

AN

ILLUSTRATED WEEKLY JOURNAL

OF

GARDENING IN ALL ITS BRANCHES.

THIS IS AN ART
WHICH DOES MEND NATURE: CHANGE IT RATHER: BUT
THE ART ITSELF IS NATURE.—Shakespeare.

VOL. V.

LONDON:
OFFICE: 37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.
MIDSUMMER, 1874.

TO THE MEMORY OF

DR. JOHN TORREY,

A GOOD MAN AND A DISTINGUISHED BOTANIST,

THIS VOLUME OF "THE GARDEN" IS DEDICATED.

ndon, June 30th, 1874.

 Abronia fragrans, 103
 Acclimatisation, 128
 Acer atheniense, 83; coriaceum 231;
 Pseudo-Platanus, 147; truncatum,
 274
 Aconitum heterophyllum, 300
 Acradenia Franklinia, 547
 Adansonia, growth of, 232
 Adenophoras, 223
 Adiantum cristatum, 182; formosum,
 158; Hendersonii, 30
 Adonises, 519
 Africa, the heart of, 332
 Agathaea celestis variegata, 10, 55
 Agapanthus umbellatus, 482
 Agave univittata, 238
 Ageratum, dwarf, 158
 Ailantus and dysentery, 524
 Alder, the, 488
 Alexandra Palace, 178, 432; Park, 88,
 344
 Allium, a new, 55
 Allotment statistics, 88
 Almond, variegated, 134
 Alnwick Castle, 100; gardens, 188
 Aloe abyssinica, 112; American, 142;
 variegated American, 400
 Alpine plants at Benthall Hall, 11; win-
 tering, 30; hardiness of, 241; rare,
 223; in Scotland, 521
 Alsophilas, 158
 Alternantheras, 419
 Alyssum saxatile, 391
 Amaryllids, hybrid, 4
 Amaryllis calyptrata, 258; new Peru-
 vian, 88; proceras, 70, 88
 Amateur's garden, the, 85; greenhouse
 and conservatory, 99; hints for, 407
 America, gardening in, 20; glasshouses
 in, 234
 American blight, 265; forest trees, 489
 Ampelopsis, 523
 Amygdalus persicaefolius ruber, 225
 Anactochili, select, 180
 Anemones coronopifolia, 440
 Anemone pulsatilla, 326; Robinsonii,
 372, 438
 Anemones as window plants, 412
 Angiopteris evecta, 415
 Angraecum sesquipedale, 28
 Animé, gum, 18
 Annuals, treatment of, 137
 Annuals and perennials in early sum-
 mer, 539
 Anthericum Lilliastrum, 440
 Anthurium Scherzerianum, 259
 Ants, cure for, 91; putty a bait for, 142
 Aphides, 2; cure for, 266
 Apple-boring grub, the, 337
 Apple marmalade, 62
 Apple tree aphides, 266
 Apples, Barchards's Seedling, 149; di-
 morphism in, 149, 525; semi-double, 254;
 extract of, 62; for Northumberland,
 61, 73; keeping, 62, 73, 186; hybrid,
 149; Lady Henniker, 149; prizes for
 new, 258; the Fig, 285
 Apricot, Kaisha, 123
 Apricots and Peaches, outdoor, 426;
 standard, 92, 186
 Aquaria, garden, 219
 Aquarium, Margate, 88
 Aquilegia chrysantha, 4; Wittmann-
 iana, 518
 Arabis rosea, 420
 Araucarias from home-saved seed, 99
 Arboretum at Walsall, new, 388
 Arborvitæ, hardiness of, 232
 Arbutus Menziesii, 522
 Architects versus landscape-gardeners,
 21, 25, 67, 68
 Arctostaphylos glauca, 524
 Argemone hispida, 95

Armeria cephalotes, 11
 Arthropodium cirrhatum, 351
 Artichokes, globe, 269
 Arundo conspicua, 534
 Asclepias curassavica, 280
 Ash, destruction of seedling, 63; and
 Oak, leafing of the, 422, 496; trees,
 dead, 510
 Ashantee vegetation, 108
 Ashton Court Grape preserver, the, 61
 Asparagus forcing, 268
 Asparagus racemosus, 243; treatment
 of, 295
 Asphodel, Poets, 295
 Asphodelus acaulis, 221
 Asplenium alatum, 243; fragrans, 182
 Asters, China, 158, 371
 Ataccia cristata, 219
 Aubrietias, 417
 Aucubas for indoor decoration, 329;
 propagating, 222
 Avenue trees, new, 489
 Azaleas, new, 226

B.

Balcony gardening, 393
 Balsam, the, 279
 Bamboo grain, 175
 Bambusa striata, 28; nana, 551
 Banana, hardy Japanese, 198
 Banyan tree, the, 332
 Barbarea variegata, 264
 Barberries, preserving, 273
 Basket, a beautiful, 56; plants for, 160,
 327; Gypsy, 483
 Baskets, hanging, 546
 Bay-tree fruiting at Romsey, 4
 Bay-trees in Devon, 344
 Beans, cooking Haricot, 102; French,
 464; forcing ditto, 269; Osborn Dwarf,
 464; runner, 229
 Bedding Calceolarias, 200; plants, 390,
 460; new, 53; spring, 417; pots, 477
 Beds, effective flower, 114
 Beech, the, 471
 Beech blight, 34, 83, 98, 148
 Beeches, B. Arnham, 17
 Beet, crisp, 180
 Beet, Chilian, 30
 Beetles, 351
 Begonia octopetala, 258, 302
 Belgian Farm gardens, 514
 Bellflowers, gland-bearing, 223; tall, 199
 Benthall Hall, Alpine plants at, 11
 Berberis atropurpurea, 125, 307; Dar-
 winii, 307
 Berberies, evergreen, 31, 63
 Beschornia Tonelli, 300
 Birds and berry-bearing plants, 3; and
 their food, 155, 162; scaring, 465, 486;
 versus Grapes, 19
 Bitter Root, the Canadian, 478
 Blackberry, Himalayan, 548
 Blackberries, 73
 Blackbird, the, 58, 110, 142; how to get
 rid of, 91; traps for, 202
 Blechnum brasiliense, 21
 Bletia Shepherdii, 281
 Blight, a new Beech, 34, 83, 98, 148
 Boiler, Meiklejohn's cruciform, 338; the
 patent Climax, 450; Cowan's, 150;
 Green's wrought iron, 150
 Bones as manure, 64; to pulverise, 318
 Border Plants, Irises as, 500
 Boronia megastigma, 482
 Boston, new park at, 28
 Botanical Society of Edinburgh, 176, 452
 Botany, Manual of, 150; Popular, 316;
 Treasury of, 100
 Bouquet Ferns, 136
 Bouquets from field and garden, 482;
 button-hole, 203; in Covent Garden
 Market, 49
 Bouvardia Leiantha, 281; tryphylla, 206
 Bouvardias, culture of, 160
 Box, a useful seed, 283
 Brainea, insignis, 413
 Brasenia peltata, 66

Bread, value of, 153
 Bremen International Exhibition, 83
 British species of Gentians, 498
 Broccoli, culture of, 84; four best, 428;
 Watts's Excelsior, 322; new, 317;
 Cattell's Eclipse, 552
 Broom fibre, 156
 Browallia denussa as a winter bloomer,
 36
 Brugmansias, culture of, 447
 Bulbous plants, 367; from seed, 55, 95;
 in Hyde Park, 362
 Bulbs, early tender, 242; rare, 116;
 winter flowering, 78
 Burnham Beeches, 17
 Butterworts, 462, 478
 Button-hole bouquets, 203

C.

Cabbage caterpillar, the, 337
 Cabbage-growing, extraordinary, 464
 Cabbages, early, 427
 Caladium, new varieties of, 9
 Calanthe curculioides, 119
 Calathea (Maranta) zebrina, 399
 Calceolarias, bedding, 77, 137, 200
 California, Orange and Grape culture
 in, 334
 Californian Lilies, 1
 Calla palustris, 140
 Calochortus Gunnisonii, 158
 Camellia, cuttings of, 213; reticulata,
 344, 368
 Camphor wood, 530
 Canadian Wonder Bean for forcing, 385
 Cannas, new varieties of, 157
 Cardamine pratensis, 440
 Carex baccans, 279
 Carnations, Perpetual, 56, 502
 Carpeting borders beneath shrubs, 30
 Carrot pudding, 273
 Carrots, cultivation of, 18; early, 269
 Caserta, Royal Gardens at, 308
 Caster-oil plants, 75, 349
 Casuarina nodiflora, 549; africana, 549
 Casuarinas, 549
 Cattleya Mossiae, 81
 Cauliflowers, culture of, 84; wintering,
 163
 Celery grub, the, 333; red, 84
 Centranthus macrosiphon, 230
 Cerasus semperflorens, 551
 Cersia Siliquastrum, 425
 Chalk and anthracite as fuel, 178
 Chamædorea Martiana, 243; Karwin-
 skiana, 531
 Chamaerops humilis, 367
 Channel Islands, trees and shrubs in
 the, 356
 Chatsworth, Victoria House at, 5
 Cheap heating of hot-houses, 474
 Cheiranthus ochroleucus, 440
 Cherries in pots, 501; new Bigarreau,
 501; wild, 395; Siberian weeping,
 524; All Saint's, 551
 Cherry-house, 548
 Chestnuts, to cook, 102
 Chimonanthus fragrans, 18, 148, 167
 China Asters, 371
 Chinese Primroses from Nice, 28
 Chiswick trials, forthcoming, 178
 Christmas Rose, new varieties of, 392
 Chrysanthemum catananche, 432
 Chrysanthemums, 350
 Churchyard trees, 124
 Cineraria, the, 351
 Cinerarias, double, 119
 Cissus, 523
 Citrus japonicus, 501
 Cladrastis lutea, 382
 Clarkia integrifolia limbatia, 28
 Clay edgings for flower-beds, 304
 Clearing ground, 358
 Clearwing, red-belted, 162
 Clematis indivisa, 260; indivisa lobata,
 328; lanuginosa purpurea, 258
 Clematises, early, in pots, 81

Clerodendron imperiale, 258
 Climatic changes, Scotch, 125, 238
 Climbers for corridors and veran-
 das, 29; stove, 136
 Clubbing, 282
 Coal, the price of, in its relation to
 horticulture, 43; new substitute for,
 108
 Cobaea scandens, 393
 Cockroaches, 555
 Cocoons, colour of, 233
 Codling moth and pigs, 441
 Cœlogyne cristata, 10, 36, 82
 Coffee, to make good, 102
 Coke dust, rooting cuttings in, 36
 Colchicum Parkinsoni, 300; speciosum,
 28
 Cold districts, wall plants for, 52
 Collector's boxes, Atkins', 78
 Collinsia violacea, 420
 Colours of flowers, the, 57
 Combretum micropetalum, 254
 Cooking apparatus, improved, 40
 Cool-house Orchids and Ferns, 6
 Coombe Wood Nurseries, the, 396
 Congress, 214
 Conifers at Penny Hill, 226
 American, 231; town, 185
 Conservatories, roof, 97; at Sunningdale,
 207
 Cordyline australis, hardy, 134
 Corn-flours, 552
 Coronilla glauca, 4, 425
 Corydalis nobilis, 500
 Corylus rostrata, 185
 Cossus ligniperda at Ghent, 4
 Cottage gardening, 248; ornamentation,
 294
 Cottages, gardeners', 435
 Cotoneaster thymifolia, 167
 Covent Garden Market, 178, 21
 bouquets in, 49; tropical fruits
 Cowan's heating apparatus, 471
 Covering, winter, 52
 Crab or wild Apple, the, 470
 Cranberries, American, 175
 Crassula quadrifida, 221
 Crataegus oxyacantha, 468
 Cress, winter, 264
 Crickets, cure for, 233, 425; R. v. m.,
 leaves a cure for, 486
 Crimson Chilian Beet, 30
 Crocuses, classified list of, 138
 Cropping, a garden, 64; advantage of,
 double, 485
 Crops, kitchen garden, 428; necessity of,
 178
 Crustaceous Saxifrages, 392
 Cryptomerias from cuttings, 205
 Crystal Palace Show, 430
 Cuckoo flower, double, 440
 Cucumbers in the open air, 464
 87; red spider on, 110; yellow
 Cucumber pickles, 406
 Cultivated fruits, Professor Asa Gray,
 the origin of, 28
 Cultivation, deep, 111
 Cupressus cornuta, 425; macrocarpa,
 253, 296; Nutkaensis, 395
 Curculigo recurvata, 467
 Currant (scarlet), 489; ditto as a bush,
 307
 Currant tea, 273
 Cut flowers, duration of, 433
 Cutting box, 283
 Cuttings, rooting in coke dust, 36
 treatment of rooted, 522
 Cyathea Cunninghamii, 9
 Cycads, ornamental, 327
 Cyclamen nook, a, 389
 Cyclamens, hardy, 70; natural, 116
 Cyclobothra pulchella, 500
 Cymbidium Mastersii, 221
 Cyperus papyrus, 504
 Cypress, the Monterey, 296
 Cypripedium irapeanum, 220;
 bile, 113; spectabile at Keble College,
 superbiens, 226; vexillarium,
 Cytisus fragrans, 200

D.

Dabeocia polifolia varicolor, 138
 Daffodils, 326, 420; true double, 278
 Dahlia arborea, 238
 Dahlia, culture of the, 369, 541; varieties of the, 543
 Dahlias, select, 349
 Daisies for spring bedding, 324
 Daisy, Ellacombe on the, 170; giant white quilled, 522
 Daphne Cneorum, 462; pontica, 395

 Daturas, flower garden, 113
 Davallia Tyermanii, 481
 De Candolle's "Prodromus," 130
 Dendrobium Boxallii, 260; Cambridgeanum, 303; Celsianum, 454; citrinum, 502; Falconeri, 432; fimbriatum occultatum, 300; Pierardi, 368; Wardianum, 260
 Deodars from cuttings, 205
 Destroying ants, 555
 Dianthus saxicola, 139
 Dickson and Turnbull's, Perth, 164
 Dicksonia squarrosa, 301
 Dictyoptera (Justicia) Tweediana, 400
 Dictyopsis Thunbergii, 534
 Didymochlæna lunulata, 413
 Dielytra spectabilis, as an indoor plant, 412
 Dinner-table decorations, well arranged, 503; Palms for the, 20
 Dionæas, 444
 Diospyros Mazeli, 156
 Dipladenia Brearleyana, 447
 Diseased Cucumbers, 385
 Dog, the best scarer of birds, 555
 Dolichos bicontortus, 225
 Domestic floriculture, 490
 Doronicum austriacum, 322, 372; Clusii, 372
 Double cropping, the advantages of, 485
 Double-flowered Lilium auratum, 10
 Double Primroses, culture of, 30
 Doum Palm of Egypt, the, 52
 Dracæana congesta, 260
 Dracænas, green-leaved, 482; in sitting-rooms, 55
 Drainage, 358
 Drawing, botanical, 316
 Drummond Castle Gardens, 442
 Dry rot in timber, 395
 Dunorlan, rock-work at, 545
 Dynamite, blasting tree-stumps with, 488

E.

Earwigs, trap for, 91, 315
 Eastbourne, new park at, 28
 Echeveria agavoides, 226; metallica, 221
 Echeverias, list of, 531
 Echinocactus myriostigma, 117
 Echinops bannaticus, 139
 Edgings, kitchen garden, 428; plastered, 347; Viola Perfection as, 500
 Edible starches, 42
 Egyptain gardens, modern, 53
 Egypt, the Doum Palm of, 52
 Elder, the, 488; v. flies, 99
 Elms in Cheyne Walk, 524
 Elms, weeping, 148
 Ely, old gardens of Bishops of, in Holborn, 70
 Embankment, new Chelsea, 322
 Endive, to protect, 84
 Epiphyllum truncatum, 502
 Epiphyllums, basket, 160
 Epithets of the month, 434
 Eremurus robustus, 50
 Erica arborea, 12, 114
 Eriobotrya japonica, 125
 Erodiums, 241; select, 179
 Eryngium bromeliæfolium, 241, 264
 Eucalyptus globulus, 204, 238, 386, 524
 Eucharis amazonica, 243
 Eupatorium ageratoides a bouquet-plant, 56
 Euphorbia jacquiniæflora, 368; splendens, 448
 Evergreens, transplanting, 394
 Everlasting flowers, 520

F.

Fashion, the inflictions of, 365
 Fences, 468
 Fencing, 358
 Fern bouquet, 136; grotto, cool, 182; insects, 486
 Fern-case, an air-tight, 546
 Fern-frond designs, 124; printing, 168
 Ferns, cool-house, 85; how to multiply Maiden-hair, 369; market, 387; mounting of, 306; stands of hardy, 329; tree, 8, 35, 158; variegated, 51; variegated v. British, 95; Tyerman's Hare's-foot, 491; British, in towns, 526
 Ferrarias, 283

Ferrieres, 266

THE GARDEN INDEX.

viii

Mantel-piece decoration, 89
 Manufactories made picturesque, 371
 Manure, bones as, 64; different modes of preparing sewage, 61; farmyard, 80; fresh leaves as, 464; new plant, 351; road scrapings as, 428; spent Hops as, 464
 Manzanita, the, 524
 Maple, the Athenian, 83; thick-leaved, 231
 Marattia alata, 415
 Marigolds, double, 540
 Maritime Alps, valley in the, 436
 Market Ferns, 357
 Market-gardens, acreage under, 112; Paris, 248
 Market, Paris fruit, 246
 Market-places, trees about, 401
 Marmalade, 273
 Masdevallias, new, 432; polysticta, 238
 Matthiola tristis, 241
 Mauritica carana, 4
 Mealy bug, 141, 162
 Medicago arborea, 148, 197
 Medicinal Rhubarb, true, 439
 Medlar, Dutch, 524
 Medlar jelly, 102
 Megacarpa polyandra, 344
 Melianthus major, 302
 Melons, French mode of growing, 373
 Mentone, contributions to the flora of, 382; Wigandia at, 462
 Menziesias, to propagate, 244
 Merendera caucasica, 243
 Mesembryanthemum truncatellum, 28; sessile album, 522
 Mice *v.* seeds, 84
 Mice, a trap for, 555
 Microscopic objects, mounting, &c., of, 99
 Mignonette, true, 182
 Mild winters, 50
 Miniature Bamboo, the, 551
 Mistletoe on the Acacia, 63; berries poisonous, 198
 Mixed planting *versus* grouped trees, 365
 Mock Orange, the, 524
 Moles, 555; in flower-beds, 202
 Monterey Cypress, the, 296
 Moneywort, 233
 Mossy Saxifrage, 325
 Moth, Whitehorn, 233
 Mountain Ash tree insects, 398
 Mucuna pruriens, 254
 Mulberry tree, Milton's, 548
 Mulchings, 486; indoor, 160
 Mushroom culture, 317
 Myosotis dissitiflora, 12, 478
 Myrsiphyllum asparagoides, 168
 Myrtle, the common, 329; cost of mutilating, 155

N.

Naples, Botanic Gardens at, 310
 Narcissus poeticus, 478; triandrus, 322
 Naturalist in Nicaragua, the, 27
 Nature printing leaves and Grapes, 209
 Neapolitan villa garden, a, 310
 Nebraska, fruit culture in, 61; fruit prospects in, 496
 Nectarines and bud-shedding, 427
 Nepenthes, 82
 Nesfield, death of Mr., 518
 Nespras, nepolica, 346, 347
 Night-blooming plants, 241
 Northumberland, Apples for, 61, 73
 Nurseries, Messrs. F. & A. Dickson & Sons', Upton, Chester, 41; Coombe Wood, 396
 Nutmegs, 133

O.

Oak-apples, or galls, 393
 Oak and Ash, leafing of the, 422, 496
 Oaks, King's Acre, weeping, 164; American, 97; singular, 238; the king of the, 22; the Yardley, 63; large, 551
 Oak woods, management of, 173
 Odontoglossum coronarium, 28, 82; Pescatorei, 160; roseum, 112; Roezlii, 28
 Oenothera serrulata, 139
 Old gardens renovated, 39
 Oldenburgia arbuscula, 547
 Oleanders as window-plants, 56
 Olives, 436
 Oncidium cheiroporum, 281; concolor, 300
 Onion, culture of the, 228
 Onion Maggot, the, 337
 Opuntia Rafinesquiana, 158
 Orange culture in the Azores, 548
 Orange and Grape culture in California, 334
 Oranges, black, 361; Californian, 134
 Orchards, acreage under, 88; Carse of Gowrie, 272; on the cultivation of 402; rules for judging, 214; Californian, 388

Orchids and Ferns, cool-house, 66; at Bridge Hall, 178; at Kew, 4; early flowering, 221, 260; in New Jersey, 182; from cuttings, 466; prices of, 258; terrestrial, 119; variegated, 180; winter-flowering, 35, 117, 135
 Orchids in teak cylinders, 547
 Orchis mascula, 478
 Oreodaphne californica, 523
 Origin of double Zonal Pelargoniums, 51
 Ornamental evergreen Berberries, 31
 Orobus vernus, 372
 Osborn's Dwarf Bean, 464
 Ouvirandra fenestralis, 222
 Oxford Road-making, 454
 Oxtan Hall, 398

P.

Pachyphytums, propagation of, 240
 Packing fruits, 123; plants, 82, 535
 Paeonias, new and improved, 477; yellow, 388
 Palm, Date, 182; in Egypt, 161; the Doum, 52; for the dinner-table, 20
 Palms, list of, 547
 Pampas Grass, male and female, 544
 Pancreaticum maritimum, 158
 Paper-reed of the ancients, 504
 Papyrus, Egyptian, 504; Syrian, 504
 Paradisia Liliastrium, 500
 Paris Boulevards, cost of planting, 205; fruit market, 246; market gardens, 248
 Paris Green, the use of, 464
 Parks and Woodlands in spring, our, 394; cost of keeping French, 344
 Parsley, culture of, 84, 111, 208; early, 269
 Pasque flower, the, 326
 Paul's (Mr. W.) Rose show, 432
 Peaches and Apricots, out-door, 426; gumming in, 92; in bloom in January, 92; ornamental, 205; root-moisture necessary for, 332; shedding buds, 169, 427, 457, 548; open wall, 270
 Peach puddings, 273
 Pears, good new, 361; Duchess de Angouleme, 314; by the sea, 61; how to convert dwarfs into standards, 225
 influence of stocks on, 245; origin of cultivated, 156; rapid decay of, 49; stewed, 42
 Pear trees in bloom, 73; Sir Phillip Crampton's, 314
 Pear wall at Holme Lacy, 168
 Peas, depth to sow, 295; early, 18, 486; early and late, 384; market-garden, 164; notes on, 237; staking, 209; to preserve from mice, 209; tried at Chiswick, 189; market, 552
 Peat and leaf-mould, 514
 Pelargoniums, a blue(?) 81, 119; a hardy, 137; Bowkeri, 119; Endlicheriaum, 241, 264; green flowered, 82; Mrs. Pollock, peculiar sport from, 392, double, 51, 103, 118, 133, 178, 264, hybridising Zonal, 118, 242; trial of, at Chiswick, 93; winter blooming, 502
 Penny Hill, Conifers at, 226
 Pentstemon humilis, 223; blue, 496
 People's Garden, the, 538
 Perennials, when to sow, 137
 Petunias, culture of, 419
 Phalanopsis Parishii, 328; Schilleriana, 243; species of, 211
 Philesia buxifolia, 212
 Phlox Boule de Fée, 258
 Phloxes, select, 179
 Phoenix Leonensis, 311
 Phygellus capensis, 284, 425
 Phyllocactus, new hybrid, 432
 Phylloxera, 278, 300, 548
 Picea, Parsonsii, 99
 Pine-apples, 232; culture of, 217; from St. Michael's, 4; in the Bahamas, 50
 Pines, flavour of winter, 186; watering, 402, 426, 440, 458, 478
 Pine, red, 205; American, 550
 Pinetum, Mr. Gordon's, 28
 Pingnicola, the, 462
 Pinon (Pinus edulis), 135
 Pinus edulis, 185
 Pinus Pinaster, value of, for sea-side planting, 395
 Pitcher plants, 82; and ants, 162
 Pits, making of, 358
 Plane, Mexican, 523
 Planes, Eastern and Western, 70; in Sackville Street, Dublin, 88; London, 63, 124
 Plane-tree, an ancient, 63
 Plant, what is an herbaceous? 544
 Plants, good hedge, 34; cases for, and aquaria, 329; collecting boxes for, 78; fly-traps, 36, 444; man-eating, 496; packing, 82; newspaper protector for, 110; Alpine, in Scotland, 521; aquatic, 220; at Benthall Hall, 11; bedding, 390; bulbous, 367; cultivated Egyptian, 199; effect of coal gas on, 502; effects of heat on, 281; for

baskets, 327; for forcing, 10; for table decorations, 377; bulbous, from seed, 55; hardiness of, 264; hardy forcing, 181; hardy, in flower in January, 12; household, 306; in vases and basins, arrangement of, 324; liquid-manure for pot, 318; miniature rock, 502; new bedding, 53; new Chinese, 134; new classification of, 518; new medicinal, 534; night-blooming hardy, 241; in bloom at Weybridge, 372; ornamental fruited, 279; out-door, in bloom, 87, 95; rare Alpine, 223; sand binding, 518; sociable, 506; spring-flowering, 347; ornamental stands for, 305; wild Egyptian, 178; the "roast beef," 50, 55; best window, 546
 Planting, ornamental, 379; seaside, 307
 Platanus racemosa, 523
 Platycodon autumnale, 199; grandiflorum, 199
 Pleiones, 280
 Plum, the Cherry, 99
 Plums, Chickasaw, 149; culture of, in Scotland, 285; new early, 73; origin of the Green Gage, 574; in Oregon, 272
 Poet's Narcissus, 478
 Poinsettia pulcherrima, 328
 Poisoned land, a, 161
 Poke-root for destroying insects, 486
 Polyanthes, 262
 Polygala Chamæbuxus, 12
 Polygonum Sachalinense, 496
 Polypodium vulgare var. cambricum, 53
 Pompeii, 311
 Pop-corn, 530
 Poppy, new double, horned, 50
 Portulacas, 241
 Post, an old, 480
 Posts, ribbon, for conservatories, 234
 Potato as a cleanser, 102
 Potato beetle, 44, 322, 385, 465
 Potato crop of 1873, 552
 Potato culture, Tillery on, 144
 Potato disease, prize essays on the, 50
 Potato essays and prizes, 177
 Potatoes and the late frosts, 486; snow-flake, 178; food-value of, 151; forcing, 269; good soil for, 230; Mexican wild, 496; new American, 111
 Potato Fungi, 70
 Potato imports, 156
 Potato trial, conditions of success in the great, 64; at Chiswick, 103
 Pots, forcing Cherries in, 501
 Preserve jars, 102
 Primroses, 262; Japanese, 284, 502, 520; culture of double, 30, 54; destroyed by birds, 388; high coloured, 304; in flower at York, 326; transmutation of, 544
 Primula altaica, 462, 478; cortusoides amoena, 417; japonica, 284, 520; japonica, American opinion of, 544; pulcherrima, 322
 Profits of Violet growing, 460
 Protection, fruit-tree, 285, 321
 Proxy voting, 344
 Pruning Roses, 346
 Prunus caroliniana, 524; myrobalana, 63, 99; spinosa, 470; triloba, 302
 Puff-ball, case of poisoning by a, 388
 Pyracantha in fruit, 4
 Pyrus Malus, 470; Maulei, 238

Q.

Quinces for tarts, 175

R.

Radishes, early, 269
 Rain-fall, 432
 Ranunculus asiaticus, 12
 Raspberries, culture of, 72, 123, 149, 168, 213; hardiness of, 244; trellis, 186
 Receipt for destroying thrips, 486
 Red Pine, 205
 Red spider, 109
 Redwood, the, 83
 Regelia ciliata, 400
 Reineckia carnea variegata, 213
 Renanthera coccinea, 220
 Rheum officinale, 206
 Rhododendron hybridum nigrescens, 226; greenhouse, 4; scarlet tree, 350
 Rhododendron sap poisonous, 198
 Rhubarb, a new, 205, 439; forcing, 268; large, 486
 Rhubarb leaves a cure for crickets, 486
 Ribes sanguineum, 489; sanguineum grandiflorum, 524
 Ribbon posts, 234
 Richardia æthiopica, 412
 Richardson's glass houses, 290
 Riviera, vegetation in the, 436
 Road-scrappings, 428
 Roads, making of, 358

"Roast-beef" plant, the, 50, 55
 Rockery, excavated, 101
 Rock-work at Dunorlan, 545
 Roffea, as a tying material, 295
 Ricinus, various kinds of, 75
 Roman gardens, 330
 Roman villas, ancient, 455
 Romanzoffia sitchensis, 223
 Rome, waterfalls near, 352
 Romneya Coulteri, 139
 Roots, bulbous, 350
 Rope-refuse for hotbeds, 160
 Rosa diversifolia, 224; intermedia, 437
 Rose-book, the amateur's, 458
 Rose-maggot, the, 337
 Roses, dimorphism in, 524; dwarf china, 412; in Turkey, 406; large Californian, 258; Ivy-leaved Geraniums a covering for stems of, 78; all the year round, 299; British, 506; for town gardens, 478, 544; for winter, 502; grafting, 277; Mr. Hole on, 321; pegged down, 521; pruning, 346; select, 438
 Roundhay Park, 156
 Royal Botanic Society, programme of, for 1874, 28, 276, 342, 364, 557
 Royal Horticultural Society, 23, 70, 129, 134, 176, 196, 216, 256, 298, 341, 429, 473, 451, 538
 Ruscus androgynus, 547
 Russell Square, exhibition of American plants in, 491

S.

Saffron, culture of, 278
 Salad plant, new, 269
 Salter, Mr., death of, 411
 Salvias, 368
 Sambucus Fontenaysii, 524
 Sandal woods, 529
 Sand-binding plants, 518, 540
 Santolina incana, 372
 Sap, ascent of the, 198, 300
 Sarracenia, 399, 446; flava, 160; new hybrid, 502; purpurea in flower at Glasnevin, 544
 Sarsaparilla, 416
 Sauce, Worcester, 175
 Saxifraga aromatica, 348; bulbifera, 476; Burseriana, 158; Cotyledon, 496; florulenta Moretti, 198; granulata, 475; hypnoides, 370; muscoides, 370; palmata, 370; peltata, 28; pubescens, 370; rotundifolia, 476; trifida, 370; sarmentosa, 329
 Saxifrages, 325; crustaceous, 239, 261, 283; Mossy, 307, 348, 418; None-so-Pretty, 475
 Scale, to destroy, 90
 Scarborough Lilies, 213
 Scaring Birds, 465, 486
 Scenery, bold variety in garden, 78
 Scions, fresh *v.* retarded, 92
 Scolopendrum vulgare var. Wardii, propagation of, 30
 Scotch Fir and its varieties, cultivation of the, 14, 488
 Scotland, climatic changes in, 125
 Scutellaria pulchella, 448; Ventinati, 547
 Sea-coast planting, 274
 Seaforthia elegans, 259
 Sea Holly Bromelia-leaved, 304
 Seakale, forcing, 268
 Sea-side, plants for the, 148, 356
 Season, and its effects, the, 194, 427, 519
 Sea-water logged land, 552
 Seed box, a useful, 283
 Seedling Amaryllis, 88
 Seedlings, how to manage, 522
 Seed ripening on cut flowers, 304
 Seeds and mice, 84; germination of, 164; vitality of, 230; when to sow flower, 137
 Senecio Mikanoideis, 412
 Sequoia sempervirens, 83
 Sermon, a flower, 449
 Sesia myopaeformis, 162
 Sewage, different modes of preparing, 61; Paris, 193
 Shading, whitening as, 502
 Shrubs, flowering lawn, 185; half-hardy, 425; pruning, 232; recently planted, 523; sea-coast, 274; spring flowering, 253, 306; variegated, 422; wall, 544
 Sibthorpia europæa as a window plant, 203
 Sisyrinchium grandiflorum, 139, 541
 Skimmas, 437
 Sloe, the, 470
 Slugs and snails, 201; destroying, 75; wall, 202
 Snowdrops *au naturel*, 345
 Sobralia macrantha, 221; macrantha nana, 482
 Soils and fertilisers, 513, 537; suitable for plant-potting, 573
 Solandra grandiflora, 103; oppositifolia, 119

Solanum betaceum, 482, 502; *ciliatum*, 225; large scarlet-fruited, 482; *rostratum*, 139
Sonchus laciniatus pinnatifidus, 203; *multibracteatus*, 534
Sorbus sambucifolia, 185
 South Australia, tree-growth in, 34
 Southernwood as a hedge-plant, 462
 Spade-hoe, 131
Sparaxis, culture of, 241; rare, 223; when to plant, 116
 Sparrows in Australia, 388
Spectator, the, on Hincksey and on gardeners, 473
Spergula lawn-turf, 496
 Spinach, Australian, 230; cooking, 552
Spiraea palmata, 540
 Spring beauty, a twofold chord of, 326
 Spring flower-beds, 45
 Spring flowers, how to make the most of, 323
 Spruce-cone ornament, 233
 Spruce Fir, golden-tinted, 18
 Squirrels in an old Oak, 205

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

CALIFORNIAN LILIES.

By DR. BOLANDER, of San Francisco.

THE genus *Lilium* is represented in the State of California by the following distinct species, of which there are several well-marked varieties:—1. *Lilium Washingtonianum* (Kellogg). 2. *Lilium Humboldtii* (Roezl), *L. Bloomerianum* (Kellogg). 3. *Lilium canadense* (Linn.); var. *L. parviflorum* (Hook.); var. *L. pardelinum* (Kellogg); var. *L. californicum* (Hort.). 4. *Lilium parvum* (Kellogg).

Bulbs ovoid, outer scales largest, fleshy, imbricated, lanceolate.

1. *LILIAM WASHINGTONIANUM* (Kellogg).—This occurs on the Cuyumaca Mountain in San Diego Co., its most southern limit known at present, northward along the western slope of the Sierra Nevada, between 3,500 and 6,000 feet altitude, in Pregou to the Columbia River, and on the coast ranges north of San Francisco, especially in the eastern parts of Mendocino and Humboldt Co. In all localities named it occurs either on ridges, or on lightly shaded slopes of ridges, having a porous loose soil, resting on a gravelly sub-soil. At no time have I met with a plant of this species in a soil the drainage of which was not perfect, and, when found on a slope, did not face towards some point between east and south. The pale loosely-scaled ovoid bulb is generally found at a depth of from 12 to 20 inches. The height of the stem, the number of whorls and of flowers on a single stem, vary very much according to soil, exposition, and age of the bulb. Much has been said about the difficulty of cultivating this beautiful species. I willingly confess that I have also met with many reverses, until I paid proper attention to its habits and habitats. If the bulb is planted at a depth of from 8 to 12 inches in a loose somewhat gravelly soil, having perfect drainage, there is no difficulty in obtaining satisfactory results. Although there is positively no specific difference between bulbs and plants collected either on the Sierras or on the coast ranges, yet I found that bulbs from the coast ranges would always bloom more readily in San Francisco (in cool houses) than those from the Sierras. The reason is obvious, but it would be interesting to know if the same holds good at other places than San Francisco. The flowers are very fragrant, and change gradually from a pure white to various shades of purple or lilac; the purplish-red spots are rather minute. The figure given in Mons. Louis Van Houtte's "Flore" (Vol. XIX.) is a very correct representation of this species.

2. *LILIAM HUMBOLDTII* (Roezl) *L. Bloomerianum* (Kellogg).—This large species has apparently a far less wider range than the preceding. It occurs mainly on the more elevated portions of the foot-hills of the Sierras, from 2,500 to nearly 3,500 feet altitude, evidently requiring a greater amount of heat to develop its full size and beauty than the first-named species. The soils in which its bulb is found are of a rather compact character, consisting of clay with an admixture of broken rocks, and a small portion of vegetable mould. Growing in open park-land, or land entirely cleared off, and therefore exposed to a hot and burning sun, and surrounded by a dry and exsiccating air, we find its bulb also at considerable depth. Its ovoid bulbs are very large and strongly built; its outer scales are largest, imbricated, lanceolate, tinged with purple, and very fleshy, well calculated to hold a large supply of moisture. A short time ago, this species was also found by Mr. Harford on the Island of Santa Rosa, opposite Santa Barbara. As far as I know, it has not yet been found on any part of the coast ranges belonging to the mainland. The plant found on Santa Rosa Island differs but slightly from that on the foot-hills of the Sierras. Its leaves are of a brighter green, acuminate, and its whorls are denser and more regular; while the leaves of plants from the Sierras are rather spatulate, and terminating with a blunt point; their green is also of a less vivid colour. The former is exposed to sea-breezes and fogs; the latter to a dry and

exsiccating air. It may be stated in connection with the above remarks, that bulbs from Santa Rosa Island do far better with us here than those from the Sierras; the reason is plain. The figure in the "Flore" of Mons. Louis Van Houtte (Vol. XIX), represents the Santa Rosa Island form as truthfully as a representation can be made. In the "Notes on Lilies and their Culture," by Messrs. Teutschel & Co., I find this species wrongly enumerated as one of the canadense Lilies. Its root is ovoid, not rhizomatous; nor does it ascend as high as Devil's Gate. What Roezl found there was one of the canadense varieties, and not *L. Humboldtii*.

Bulbs rhizomatous with short fleshy scales.

3. *LILIAM CANADENSE* (Linn.)—*a.* Var. *L. parviflorum* (Hook.); *b.* var. *L. pardelinum* (Kellogg.), (var. *L. puberulum* Torr.); *c.* var. *L. californicum* (Hort.), (var. *L. Walkeri* Wood), (var. *L. Hartwegii* Baker). The above enumerated varieties of this species demonstrate the influence of soil, location, and climate more forcibly than any other species of our Lilies, because it is more generally distributed, and has a wider range throughout the entire State. It is, therefore, not to be wondered at that so many excellent botanists described different forms of this variable species under so many different names.

a. The form of *L. canadense* var. *parviflorum* Hook. occurring largely in boggy soil, west of the great Redwood belt, and on the immediate coast, presents even there differences in size and form, well calculated to lead astray. Here, wherever exposed to the daily continuous westerly winds, it attains hardly 2 feet in height, bearing often but a single small flower of a deep red colour, with the sepals but slightly recurved towards the tip; but wherever sheltered, either by trees or shrubbery, it attains a height of from 3 to 5 feet, bearing numerous flowers of a less reddish tint, and arranging its leaves, at least a part of them, in whorls; while those of the exposed plant are all scattered, and few in number. This form extends along the immediate coast from Vancouver's Island to Oregon and California. This long linear extension and range is common to many plants of the immediate western coast.

b. Proceeding, however, eastward, along a stream into the interior, to a point where the coast climate changes gradually into that of the inland-coast valleys, and where an abundance of sunshine and shelter is added to that of moisture, we find the beautiful and charming form described by Dr. Kellogg under the name of *L. pardelinum*. Here in deep recesses on the banks of streams, in such favourable localities, the plant attains a height of from 6 to 9 feet; here its rhizomatous bulb ramifies and multiplies rapidly, forming clusters several feet in diameter. Stems shoot up, side by side, from every terminating point of the ramifying and radiating bulb, giving the plant a gregarious appearance. Perhaps nowhere, in this state, is this gregarious character so well and plainly exhibited as in the Bear Valley on the Sierras, at an altitude of 4,000 feet, where acres of a wet meadow are densely covered by this magnificent variety. The whorls are here usually broken up, and the large leaves are indefinitely scattered all over the huge stems, which are variously branched, bearing numerous flowers, with strongly recurved perianths of a bright yellowish-red colour, copiously spotted with purple spots on the face. But, if we proceed from the inland coast valleys farther eastward, and enter the large valleys of the interior, where the climate is hot and the air dry, we soon lose sight of this plant, even on the banks of streams. Crossing these valleys, and ascending the foot-hills of the Sierras to an altitude of from 2,500 to 4,000 feet, we meet it again in all its glory in wet localities. Growing in wet boggy soil, mostly subject to overflowing at some time during the year, its bulbs are imbedded but a few inches beneath the surface of the soil. At San Francisco it blooms readily in cool houses.

c. The next marked form, *L. californicum* Hort. (*L. Walkeri* Wood, *L. Hartwegii* Baker—*L. puberulum* Torr.), differs very strikingly from the preceding variety in the form and arrangement of its leaves, and in habitat. The leaves are usually arranged in dense and numerous whorls; only the uppermost are scattered, linear-lanceolate, acuminate, and of a dull green colour; while those of the preceding form are mostly spatulate, or oblanceolate, and of a bright green colour. This form we find on moist slopes of the lower foot-

hills of the Sierras, as well as of those of the coast ranges, where the climate approaches more or less in character that of the interior valleys. In these thus characterised localities the plant is neither copiously supplied with moisture by heavy dews or dense fogs, nor by an abundance from below.

4. *LILIUM PARVUM* (Kellogg).—The specific name of this species refers solely to the small size of the flower, for, in every other respect, this plant attains as large a size as any other of our Lilies, if not larger. It begins at an elevation in the Sierras, where, to my knowledge, *Lilium pardelinum* ceases to grow, namely, at an altitude of 4,000 feet, and extends upwards to 8,000. It is found growing exclusively on the banks of mountain streams, or in shady swampy places, through which a constant stream of cold water runs. The leaves are mostly scattered over the entire stem, spatulate or oblanceolate, and somewhat glaucous. The ramifications of the branches and the number of flowers depend upon the size to which the plant develops. The perianth is of an orange-yellow, spotted with purple, and but slightly recurved at the tip. Its cultivation seems to offer more difficulties than any other of our species.

Botanists, either collecting or studying Californian plants, cannot bestow too much care upon their habitats; and can never possess, of one and the same species, too large a quantity of specimens, collected at different localities. In a country like this, where there are, in fact, but two seasons, the wet and the dry, passing abruptly from one into the other—the proximity to, or the distance from, the foggy coast, the general physical and mechanical properties of the different soils, the elevation, the exposition (whether west and north, or east and south), and the distance from the rainless belt bordering this State in the south, or from the rainy belt approaching it in the north, must be carefully taken into consideration. Omitting, for the present, any remarks on those parts of California situated south of latitude 35°, and those north of latitude 40°, there are, distinguishable in middle California, the following ten well-marked botanical regions, or belts, from west to east:—1. The immediate sea-coast belt; 2, the redwood belt; 3, the hilly or mountainous park and *chaparral* belt; 4, the Sacramento and San Joaquin valleys; 5, the lower foot-hills of the Sierra Nevada to 2,000 feet altitude; 6, the middle Sierra belt, between 2,000 to 4,000 feet; 7, the higher Sierra belt; 8, the Alpine region; 9, the eastern slope; and 10, the eastern basin. The characteristic plants of these various regions or belts, their climates, and their influences on plants, will be the subject discussed in a future article.

GARDEN INSECTS, AND MEANS FOR THEIR DESTRUCTION.

By THOMAS BAINES, Southgate.

Aphides.

THERE is no insect that preys upon such a number and diversity of plants as the numerous species of aphides. On the soft leaves of the Cucumber and Cineraria, the tender shoots of the Heath and hard-wooded New Holland plants, the young delicate foliage of the Peach, and the deciduous tree of a hundred years' growth, some species of the destructive family seem equally at home. In many cases, from their numbers and the wide field of their attacks, it is impossible to do anything for their destruction. But on all plants grown under glass, as also the better class of outdoor fruits, it is imperative to destroy them. The means for their destruction, in many cases, must be modified according to the different description of plants they infest, as the remedy that may be safely employed in the case of one plant would be death to another, similarly applied. Fumigation with tobacco, or the numerous preparations made from it, is the most general as well as the best method for their destruction under glass; but, even here, there are numbers of plants upon which they cannot be killed by this method without serious injury to the plants. This is the case with many Orchids, more especially the thin-leaved kinds, such as *Dendrobium Devonianum*, *D. Falconerii*, *D. chrysanthum*, *Cælogyne cristata*, some *Odontoglossa*, &c.; consequently, where these and similar plants are grown in a house

that it becomes necessary to fumigate, they should be removed. And I may here remark that the more heat, shade, and moisture that is used in the cultivation of this class of plants, the more liable they are to suffer from the effects of fumigation. When such plants as those above indicated are attacked by aphides, they should be carefully but thoroughly washed with a fine syringe every three days, for a time, using clean water. Some Ferns, such as the young unmatured fronds of *Adiantums*, and *Tree-Ferns*, unless grown very cool, suffer from smoke; these are best dipped in tobacco-water, just sufficiently strong to kill the insects. For the generality of greenhouse plants, when affected, fumigation at intervals of ten days, until the plants are quite clean, is the best remedy; but such plants as herbaceous *Calceolarias*, *Cinerarias*, and *Pelargoniums* in flower, must have a mild application of the smoke or they will suffer. Amongst hard-wooded plants, *Aphelexis* frequently are attacked by aphides, but it requires an experienced eye to detect them, as these plants, like many others, have great influence on the size and colour of the insects. On the *Aphelexis*, they assume almost the exact colour of the plant, and appear so sickly and small as to be scarcely discernible; yet, if allowed to remain unmolested, they quickly destroy the flower-buds and turn the young leaves yellow. Their presence may be detected by their excrement on the leaves near the points of the shoots; it has the appearance of small white crystals. It is scarcely possible to kill them on these plants by fumigation. Syringe with strong tobacco-water, laying the plants on their sides over any vessel that will catch the liquid. In the plant-stove they much seldomer make their appearance on account of the atmospheric moisture and frequent application of the syringe. Yet, when necessary to fumigate, there are few plants here, except such tender-leaved things as *Torenia asiatica*, that will suffer. Cucumbers and Melons, especially in low pits and frames, are delicate subjects to fumigate, and, when affected with these insects, should have the smoke applied with great care, a little and often until the plants are clean. But, in smoking plants in small places, such as garden-frames, there is always danger, as in such small space the smoke gets out before it has time to effectually kill the insects, necessitating a stronger application than the plants frequently can bear. Covering the lights with mats assists the retention of the smoke. Damp mild evenings are the best for the operation in any structure. As an additional and important means for the destruction of these insects under glass, I always have in readiness a few gallons of tobacco-water, with which to wash any plant as soon as it is discovered to be affected. The "stitch in time" principle applied in this way, instead of allowing the insects to increase and spread, saves much labour and expense.

In fumigating plants, either in large or small houses, it should always be borne in mind that the nearer the plants are to the roof the more certain is the destruction of the insects, the smoke being the most dense near the top of the house; it will also be obvious that the closer the laps are in the glazing, the more effectually will the smoke do its work; where the laps are open it is good practice to cover them with mats, or any available material that will assist in confining the smoke. In the case of plants that will bear syringing overhead with clean water, it is well to give them a good washing the morning after; any of the insects that are nearly, but not quite, killed will receive the finishing stroke by this. Whatever material is used for fumigation, tobacco, tobacco-cloth, or paper, see that it is sufficiently moist to prevent its flaming, or it will do serious harm to the plants. The operator should always stand outside till the house is sufficiently full of smoke, to see that the material does not burst into a flame, but simply smoulders. A good plan is to sprinkle a little damp *Sphagnum* over the material as soon as it is ignited; it cools the smoke and prevents flame. Care must also be taken, that whatever is used to ignite the fumigating material is such as will contain no deleterious gases likely to be injurious to vegetable life. Coal in a half-burnt state is liable to do much harm in this way. Wood-embers, charcoal, or a little coke is the best. The material should always burn quickly, throwing up a dense volume of smoke, so as to fill the house in as little time as possible; there is then less danger of dryin

the atmosphere of the house so as to be injurious to plant life. In the density of the smoke required to kill the insects, the operator must be guided by his knowledge of the strength of the material he is using, the size of the house, and the description of the plants it contains. The larger the house the less danger I have found of injuring its occupants by fumigation; consequently, such houses may be filled more densely with the smoke than plants in small houses will bear. Pot Roses are very liable to suffer from fumigation, unless the application is very slight. With such plants as the above, frequent and weaker smokings are the safest. If *Pelargoniums* are fumigated when in bloom, the flowers generally drop, consequently attention should be given to see that the plants are quite clean before the flowers begin to open. The flowers of *Spiræa japonica*, in every stage of development, are generally spoiled if fumigated. The implements used for fumigating are various, from a garden-pot with a hole in the side to those mechanical contrivances that are frequently making their appearance, but which are more for sale than use. The fumigators which I have had in use for fourteen years, and which are the best I have seen, are made of strong sheet-iron riveted. They are 10 inches in diameter by 9 inches deep, on three legs $1\frac{1}{2}$ inches high; the bottom and sides, half-way up, are perforated with holes one-eighth of an inch in diameter, one inch between the holes; it has a stout handle at the side much like that of an ordinary saucepan. This is much better than a handle across the top, as, if the material does not burn freely, it can with more convenience be taken by the handle and swung repeatedly backward and forward, the draught quickly causing it to burn freely. I use one of these fumigators at each end of the house requiring smoking, by which means it is filled more rapidly.

Plants that have been fumigated over-night are better for being shaded the day following if the sun shines brightly. The fumigation of individual plants out of doors under improvised coverings, as is sometimes done, I look upon as a mistake; half the time and equal cost in material in the shape of a good syringing with tobacco-water will not only kill the living insects, but also destroy the eggs, which fumigation leaves unharmed, and ready to come into life in less than a fortnight from the time they are deposited. There is no plant that suffers more from the ravages of aphides than the Rose, and, where they are grown by the acre, as is the case with those in the trade, it is a difficult matter to do anything with them, but on open exposed grounds of large extent, such as those who cultivate for sale usually have, they do not so often make their appearance as in the often confined and over-sheltered plot of the amateur. Here they are to be met with almost as certainly as the return of spring, and, if they make their appearance whilst the leaves are not fully developed, and yet tender, the best means is a good syringing with tobacco-water. Further on in the season, when the foliage becomes harder, syringing two or three times a week with clean water, or, still better, the use of the garden-engine will keep them clean; the insects are not able to withstand the continuous application of water, and here it can be used with good effect to the plants in other ways besides the destruction of the insects. Dahlias, Asters, and Verbenas are all plants on which they thrive apace, and, as a general rule, the better the plant suits them, the more injury they do to it. These, and other plants of similar character, require the same treatment as Roses. Peaches and Nectarines are especially their favourites, and the trees are few that escape their attacks every spring, sometimes before, but often just as the trees go out of bloom. They may easily be detected by the leaves beginning to curl before they are half developed. A diligent look-out should be kept at this time, and not a day should be lost, as soon as they are discovered, in syringing well with tobacco-water the parts affected. But this is not always effectual unless the trees are syringed with the tobacco-water all over. This I always do as soon as any insects are discovered, and one dressing of this description is sufficient, for as soon as the leaves get further developed, they will stand the use of the garden-engine, used with care regularly twice or thrice a week, which keeps in check those and other pests. Cherries on walls are often attacked by the black aphid. This is one of

the worst of the family, as it is harder to kill than the common green aphid, and sometimes requires a second application of the tobacco-water. In washing all trees attached to a wall, the operator should stand sideways to the wall, so as to get the liquid as much as possible to the underside of the leaves; by this means there is less waste of the liquid employed. With the same object, a fine-rosed syringe should be used. The amateur who does not happen to have more than a few trees, will find the soapy water from the laundry not a bad substitute for the tobacco-water, used in the same way. Chrysanthemums, more especially such as are grown in pots, when out of doors in summer, are very liable to the attacks of aphides; dip the points of the shoots as soon as the insects are discovered, and afterwards syringe every evening with clean water. This will keep them free from the insects, and benefit the plants in other ways. There is one species of this insect that attacks the roots of Lettuce in summer, frequently destroying the crop in a few days. There is no warning until the damage is too far done to be repaired. The first evidence of their presence is given by a few plants suddenly flagging in the sun. If the roots are examined, they are generally found swarming with the insects. When such is the case, nothing can be done to save the crop. As a preventive, from the middle of June to September, as soon as the plants get a couple of inches high, we give them a good dressing round the collar with soot, washing it well down to the roots; this, generally, is effectual. With bush fruits, especially Currants, which often suffer severely from the ravages of these insects, where they are largely grown, the cost in labour would be too much; where the number of trees are small, if the insects are attacked as soon as ever they make their appearance, they may be destroyed with clean water from the garden-engine.

BIRDS AND BERRY-BEARING PLANTS.

THERE are few who would not endorse the remarks of "D. T. F." (see p. 521, Vol. IV.), regarding the wholesale disappearance of our Holly and other winter berries. I would, however, rather protect as many berries as would be required for Christmas decoration than destroy the feathered delinquents that feed upon them at this season. Here we have very fine Hollies, which literally bend down every season owing to the load of berries which they bear, and which attract swarms of birds. Hundreds of wood pigeons also eat enormous quantities of them in a single day. With the exception of the pigeons, the fatal barrel is never pointed at one of these depredators, which, at this season, are in their prettiest plumage, and much to be preferred even to the berries themselves, which are at best short-lived. I have always found a stuffed cat or two, placed in some of the most conspicuous trees, a complete protection from birds of all kinds. Not only do they frighten the small birds, but they also keep rooks from building in our large Holly trees in spring. Until we used the stuffed cats, no other means that we tried would frighten them. The high gales of wind which we have had during this month have strewed the ground under the trees with berries. I have always observed that here in very mild seasons the berries of Hollies are ready to drop off at a touch, a circumstance easily accounted for when we consider that evergreen trees in winter are susceptible of the smallest change in the atmospheric temperature. As a proof of this, I may state that here the catkins upon the common Bay are from an inch to two inches long; indeed, a few more mild days would have induced some of them to develop their flowers. It is something remarkable that during such a mild and open season, the small birds referred to by "D. T. F." should have been so destructive to his winter berries. Were it not for the fieldfares and wood-pigeons, all the berries that small birds eat here would be only a grain, as it were, from every bushel: it is, however, almost incredible what pigeons and fieldfares can devour in one day. Like "D. T. F.," I find little birds to be most destructive in spring to the fruit buds of bushes in particular; yet I spare them, not, I hope, from any absurd sentimental feeling, but because they have life and beauty, and suffer and rejoice under the various operations of nature like myself.

J. T.

NOTES OF THE WEEK.

THE house at Meecham Place, Newhaven, is now covered on all sides with *Pyracantha*, in full berry, to a height of two storeys and more. So striking a picture is not afforded by any other shrub or wall-plant at this season. We have, by the way, long observed the *Pyracantha* to be a good sea-side tree.

REPORTS reach us from all quarters as to the damage done to the flowers of Orchid and other choice plants by the late dull foggy weather. In some establishments scarcely an expanded flower escaped, and even the unopened buds in many cases damped off, from causes wholly beyond the cultivator's control. *Calanthes* suffered severely, and the damage appears to have been greatest in the warmest houses.

PASSING the pretty churchyard of the village of Bletchington, between Newhaven and Eastbourne, the other day, we were surprised to see a number of neat bushes of the well-known bright yellow Pea-flowered plant, *Coronilla glauca*, flowering as freely and well in the open air as they ever do in the greenhouse—a fact worth remembering by those having gardens by the sea and in mild districts.

WE have to thank Dr. Bolander, of San Francisco, for the valuable contribution on the Lilies of California, which forms our leading article this week. As these superb hardy Lilies are now being freely distributed in our gardens, this contribution as to their history will prove useful. Dr. Bolander considers it desirable to call attention to the needless multiplication of species. He holds there are four species and no more, and that those are easily distinguishable by the roots. Various handsome forms, reputed to be species in this country, are considered by Dr. Bolander to be varieties of the Canadian Lily.

ENGLISH-GROWN Pine Apples long maintained the reputation of being of finer quality than imported fruit of that kind. Now, however, they are surpassed in winter by those from St. Michael's, from which we get the same kinds as we grow at home, and like them, too, are grown under glass. They arrive in our markets in excellent condition, averaging from 3½ lbs. to 7 lbs. in weight. On Monday last a large consignment of these Pines was disposed of by auction at prices ranging from 15s. to 21s. a piece, and the salesmen greatly prefer them to home-grown produce, inasmuch as they are of decided soundness in the heart, whereas English Pines, though externally to all appearance sound, are sometimes discoloured at the core, and not unfrequently quite black.

ORCHID-GROWERS, who have long been accustomed to look upon the collection of these plants at Kew as most unsatisfactory, as far as good culture is concerned, will be pleased to learn that it now shows signs of vigorous improvement. A good collection of Orchids is always interesting; but it is in a botanic garden that we look for those minute or inconspicuous species not to be found elsewhere in cultivation. The Kew collection is rich as regards species, but not more so than one or two other collections that might be named, while the introduction of really new kinds is left almost wholly in the hands of our leading nurserymen. Considering the facilities which Kew possesses for the introduction of new plants, surely Orchid collecting should not be overlooked.

WE have received from Mr. Batters, Chilworth Manor, Romsey, beautiful branches of Sweet Bay, loaded with fruit as large as wild Cherries, and with them the following letter:—"Bay-trees flower, set, and ripen fruit freely here. You will see that they are heavily laden with berries, which the birds have just commenced to clear off, and in two or three weeks they will, doubtless, have completed their task. We have a golden (or yellow) berried Holly, about 30 feet high, densely covered with berries, but it will soon share the fate of the Bay, and be stripped of its beauty. *Cotoneaster Simmondsii*, although the plant is young, bears its pretty red berries in abundance. We have it as a (small, at present) pyramid on the Grass. We are, I believe, something like 220 feet above sea-level. The soil is of a poor white gravelly character; *Rhododendrons* thrive luxuriantly in it, as do also Laurels, and many other shrubs, but, for kitchen garden-
ing in dry summers, it is not so suitable."

THE Rev. Mr. Ewbank, St. John's Vicarage, Ryde, writes to us as follows respecting vegetation in the Isle of Wight:—"I can add," he says, "to the list (see p. 536, Vol. IV.) two or three things which seem to do exceptionally well here. *Rhynchospermum jasminoides* I planted in the open ground in my garden three or four years ago; and it has done remarkably well, last summer it was full of blossom; *Stauntonia latifolia* is covering the porch of my church, and appears likely to prosper; *Ceanothus rigidus* is a delightful wall plant here, and, like *Ampelopsis Veitchii*, it seems to grow by magic. Last week I had more than thirty shrubs and flowers in blossom at one time. Among them were *Gentiana acaulis*, *Erica carnea*, *Berberis Darwinii*, *Souvenir de Malmaison*, and other Roses. *Narcissus* and *Anemones* are also in flower in the open ground, thus indicating what

a forward state of things we have here. Another plant that I should have named is *Lardizabala biternata*. It is covering the east end of St. John's Church, and its glossy foliage is worthy of great admiration.

THE naked-flowered Jasmine (*Jasminum nudiflorum*) is now in full blossom in many gardens about London, and, when intermixed with Ivy, its beauty is enhanced. In the Victoria Nursery, at Holloway, it is grown in small pots for conservatory decoration. It has been very fine throughout the southern counties this winter. By far the best effect is obtained when the flowering shoots are not rigidly trained to the wall or other surface, but allowed to hang gracefully down.

THERE are just now some two or three dozen very showy hybrid *Amaryllids* in flower in Messrs. E. G. Henderson's nursery at St. John's Wood. They appear to be intermediate between *A. aulica* and *A. pardina*, and, during the winter season, their large flowers will prove useful, either in a cut state, or for ordinary decorative purposes.

MESSRS. BLACKWOOD & SONS announce a new illustrated work on "Domestic Floriculture, Window Gardening, and Floral Decorations," by Mr. F. W. Burbidge. The subject of indoor floral ornamentation is now becoming one of general interest, and any work in which it is well treated can hardly fail to be received with favour.

WE have recently seen the rare and beautiful Palm called *Mauritia carana*, growing freely in the Wellington Nursery. It has slender smooth cylindrical leaf-stalks, from 1 to 2 feet high, from the apex of which the umbrella-like segments of its leaf diverge equally on all sides. Above, the foliage is of a glaucous hue, but below it has a bright silvery aspect, which gives it a very interesting appearance; like its congeners, it requires treating as a sub-aquatic.

THE different varieties of greenhouse *Rhododendrons*, such as *R. Princess Alexandra*, *Princess Eleanor*, *Brookei*, *jasminiflorum*, and *javanicum*, are now flowering freely in the Royal Exotic Nursery, Chelsea. They grow freely in a warm greenhouse, and bloom for months together, while their clear waxy flowers are invaluable for bouquets and for other kinds of floral decorations.

WE are informed, by M. H. J. Van Hulle, that the Elms on the Boulevards at Ghent are at present threatened with total destruction from the ravages of what appears, from M. Van Hulle's description, to be the caterpillar of the goat moth (*Cossus ligniperda*), described at page 203, vol. III. of THE GARDEN. Young trees (of from seven to twelve years old) chiefly are attacked, and many of them are already dead. The caterpillar of the goat moth is the special scourge of the Elm and the Poplar, and, when it has once established itself to any extent in a tree, we believe there is no remedy for it.

MR. C. S. SARGENT, of Boston, who is now in this country, and who is well acquainted with American plants, informs us that *Aquilegia chrysantha* is the finest herbaceous plant yet introduced from America. We subjoin Dr. Gray's remarks on the plant from a late number of the *Proceedings of the American Academy*, for which we have to thank Mr. Sargent. Upon first acquaintance with this plant in dried specimens, I regarded it as a variety of the blue, long-spurred *Aquilegia* of the Rocky Mountains, some forms of which are almost or entirely white-flowered. In view of the diversity of colour, and this more remarkable deviation to yellow, I was the more disposed to follow Sir William Hooker in preferring Nuttall's appropriate name of *A. leptoceras*, trusting that the *A. leptoceras* of Fischer might not be a good species. But now that we have this golden Columbine in cultivation for the second season, and can review its characters, we must conclude that it may claim a distinct specific name, although the technical characters may seem to be slender. Its geographical range is different; it occupies a more southern range, and is found at less elevation than *A. cærulea*. Here, at least, it is more hardy, probably because it bears our summers better than its Alpine relative, and endures our winters perfectly. It is much taller, rising to the height of 4 feet in the rich and moist soil which it prefers; it comes into flower nearly a month later, branches freely into a panicle, and continues in bloom through the whole summer. The colour of the blossom is a clear yellow, the petals of a rather deeper hue than the sepals. The sepals and the limb of the petals are not so ample as in *A. cærulea*, the former hardly exceeding an inch in length and five lines in width; they barely equal the latter in breadth, and do not much exceed them in length. The long spurs are similar, very slender, and over two inches in length. If the flowers individually are not so showy as those of *A. cærulea*, they make it up in their number and longer continuance, and are remarkable for their colour. It is a native of Eastern New Mexico (Organ Mountains not far from El Paso, (Thurber, Wright; and further north, Parry), to Arizona (Mabibi, Parry, &c.) Also in South Utah. Now in cultivation from seeds collected by Dr. Parry, and distributed from the Botanic Garden of Harvard University.

THE GARDENS OF ENGLAND.

CHATSWORTH.

It was just fifty years, last June, since we first became acquainted with this Palace of the Peak, about the time when the late Duke of Devonshire had commenced those extensions of the mansion which took so many years to complete. Then Chatsworth was comparatively a small place, and, from a gardening point of view, was not equal to many other places in the midland counties; indeed, it was not until Sir Joseph, then Mr., Paxton took charge of it, that any decided steps were taken in gardening, and those steps were not in the happiest direction. The great error which Paxton committed was that of not removing the forcing-garden from its present ill-chosen position; for, make the best you can of it, the situation is as bad as could be found upon the whole estate; low, cold,

produces from ten to fifteen hundred magnificent fruits annually, and those of the finest possible quality. (If you want a superior Peach or Nectarine go to an old tree, as they will always afford the finest-flavoured fruit.) In the history of this Peach, and, indeed, of many more at Chatsworth, the fact cannot be resisted, that the roots during wet seasons must be constantly immersed in water, and yet Peaches are forced both early and well. This is a singular anomaly, over which young gardeners may ponder possibly with profit. In the management of his early Vine borders, the gardener, Mr. Speed, finds it expedient to cover them, so that between autumn and the advent of warm spring showers, not a drop of water falls upon them. For this purpose he uses what are called common pantiles, and these, while allowing a free passage of air to the soil, carry the water all off effectually. It was in a border thus protected, and from the rejuvenated old Vines of thirty years' growth, that Mr. Speed exhibited the bunches of

Interior of the Victoria House at Chatsworth.

and always damp, being but a few feet above the level of the Derwent, which runs close by, the finer varieties of fruits refuse to ripen, while vegetables are weeks later in coming to maturity than in other gardens close by; this is very disheartening to a gardener, but he has no remedy except patience, and the protection of glass, which cannot be used with advantage everywhere. Paxton tried the scheme of throwing the surface of the garden into broad ridges sloping to the south, but after several years trial it was abandoned. A low and damp garden is, however, not an unmixed evil, for in the parching summer of 1868 the crops of Strawberries and vegetables at Chatsworth were magnificent, and the envy of all who saw them. This gain, however, was but transient, for, when the rain and frost came, vegetation suffered severely. Still, for all this, there are some fruits which do well under glass at Chatsworth; as for example that grand old Royal George Peach, which, filling two or three houses,

Grapes which created such a sensation at the Oxford Meeting of the Royal Horticultural Society in 1869. Bunches such as these were, for size of berry and finish, are rarely seen; in fact the house taken as a whole from that time till now, has been year by year equal to the best we ever saw.

The Victoria and Amherstia Houses.

We cannot leave the kitchen-garden without saying a word about the Victoria and Amherstia houses. The former is a very suitable and handsome building, but, like all similar buildings which have to contend constantly with the alternations of heat and moisture, it is fast going to decay, and must at no distant date be renewed. Seen in the summer season with the broad and singular leaves of the Victoria floating upon the water, and the different varieties of *Nymphaea Lotus*, *Limnocharis*, &c., in the corner tanks, and the immense masses in baskets depending from the roof, this is certainly one of the most interesting houses in a very interesting place.

The *Achimenes*, and here let us remark that the older species and varieties only are grown, or rather are found suitable for basket growth, are in their season most effective. They consist of *A. grandiflora*, *longiflora* and its white variety, *Verschaffeltii*, and the old *coccinea*. To say that these plants at Chatsworth are used by thousands, is not to exaggerate, for no doubt thousands of each kind annually find their way into these baskets, which form globes from 5 to 7 feet in diameter, and as much high. Some conception may therefore be formed of the truly regal manner in which the *Achimenes* is grown at Chatsworth. The *Victoria* house is square in form, and has a flat ridge-and-furrow roof, 61½ feet long, 46½ feet broad, and about 23 feet high, and contains a circular tank 33 feet in diameter, surrounded by a pathway, whilst the four angular corners are each divided in the middle by a path, thus converting them into eight compartments, which are used as tanks for the growth of *Nymphæas*, *Nelumbiums*, and other tropical aquatics. The large or central tank contains another tank 16 feet in diameter, and considerably deeper than the outer portion; this contains the soil in which the *Victoria Lily* is planted. The walls of the tanks are built of brick, and the bottom is paved with stone; the tanks are lined with lead throughout, and the 2-inch hot-water pipes which supply them are also made of lead. Whilst the plant is growing, a little wheel, in the form of an overshot mill-wheel is fixed near the edge of the tank and continually kept in motion by a small jet of water from a tap immediately over it; thus the surface of the water is always rippled. The *Victoria regia*, being an annual, dies in November, when the water in the tank is drained off, and the soil contained in the inner part removed. The *Lilies* in the angular tanks, being also out of season, are, about the same time, mostly cleared away and stored in troughs filled with water in the Cucumber-house. The aquarium, thus stripped of its summer occupants, is filled in winter with large *Chrysanthemums* for furnishing cut blooms. As the *Victoria Lily* annually produces and ripens a good stock of seeds, these are preserved in vessels of water until sowing-time comes round, which is generally about the middle of December, or between that and January. The plants are potted singly, and re-potted as they advance in growth, until they have attained sufficient strength, when the best plant is planted out in a heap of fresh soil. Just now two pots containing loamy soil and sown with seeds of this noble *Lily* are in the tank containing the *Nymphæas* in the Cucumber-house. At Chatsworth this Royal Water *Lily* luxuriates better and flowers more freely than it does in any other place in the country; the largest leaves in summer measuring as much as 7½ feet in diameter.

Of the *Amherstia*, well, perhaps, not this, but the first introduced into the country by Gibson, we had the first charge on its arrival in England. Its early history was a struggle for existence; the first blooming, not of the Chatsworth plant, but of that at Ealing Park, a triumph; now, however, it blooms so freely every summer as almost to have ceased to be a novelty. It is a tree of noble aspect, with large pinnate leaves, unfortunately highly attractive to thrips, red spider, and other insect pests. To subdue these requires almost daily attention with sponge and soap, but the glorious inflorescence when it comes, in long spikes of bright and singular flowers, fully repays the trouble. At Chatsworth the house is much too small for the plant to be seen in a proper manner. To grow the *Amherstia* properly would require a house, circular or octagonal, at the least 30 feet in diameter, and 20 feet high. Then the noble proportions of this plant could be seen, and its cultivation be developed in the best manner. The *Amherstia* is a difficult plant to propagate, hence its scarcity. At Chatsworth some few plants have been rooted from layers, but not in any great quantity. The tree at Chatsworth is planted in a bed of good loamy soil, and is regarded as the finest in the country. The spread of its branches covers a space of some 26 feet, and in March it is one mass of bloom. The young leaves, being of a pale reddish hue, are also very beautiful. Beneath the tree, placed on the surface of the soil, are many varieties of *Marantas*, *Alocasias*, *Dracænas*, &c., that grow and thrive apace in the hot vapour bath in which the *Amherstia* delights and under its partial shade. Here, too, in a corner, and growing in a

pot, is a very tall plant of the *Upas* tree of Java, which has a clean stem several feet in height, surmounted by a much-branched, leafy, and healthy top. Two sides of the octagon form a wall, to which adhere a variety of climbers, such as the *Cissus discolor*, *Æschynanthuses*, *Vanilla*, and others. Associated with the *Amherstia*, is a collection of *Pitcher-plants*, perhaps the best grown in the country, inasmuch as from the smaller species, such as *lævis* and *phyllamphora*, pitchers may be cut by the thousand. These stand upon a raised platform over the hot-water pipes; consequently the heat is considerable, and the moisture abundant. The plants are trained perpendicularly, close to the front glass, and Mr. Speed has found that the less they are shaded the finer is his crop of *Pitchers*. Well, this is just a natural consequence. Our past, and to some extent present, rule of shading tropical plants is a mistake, and in no place can one have the fact more fully demonstrated than at Chatsworth, for there, in the large conservatory, shading is impossible, and yet one finds in it some of the finest tropical plants in Britain. As regards *Pitcher-plants*, the less they are shaded the more profusely do they produce *Pitchers*. They enjoy a porous soil, through which heat and moisture will pass freely, indeed, if you allow a root to stray into the trough of a hot-water pipe, the amount of heat that it will stand and enjoy is something extraordinary. *Pitcher-plants* strike readily but not rapidly from cuttings made of free-growing wood and placed on a brisk bottom-heat, and the best medium for the purpose is the Derbyshire spar broken to the size of Peas. In that they will form a bunch of spongioles or rootlets almost as fine as a sponge, and with them carry the spar. The best compost for them afterwards is *Sphagnum*, spar as before stated, charred cowdung, and just a little turfy Peat. These intimately mixed and used in a rough state, with a brisk moist bottom and plenty of water in the growing season, will produce *Pitcher-plants* in first-rate style.

The Conservatory.

This magnificent curvilinear structure is one of the largest plant-houses in the kingdom, and is entirely glazed on the ridge-and-furrow system. It is 282 feet long, 120 feet broad, and 60 feet high, with a balcony surrounding it inside, like that in the Palm House or Winter Garden at Kew, and ascended by means of a winding staircase rising out of a great mass of rock-work. It is heated by means of hot-water pipes contained in chambers underneath the floor, the heat having access through gratings to the body of the building. The flue for conveying the smoke from the furnaces does not rise in or near the conservatory itself, but the smoke is conveyed in a tunnel for a considerable distance away, and then is emitted through a large chimney-stalk. The house inside is surrounded by a walk, between which and the glass there is a broad plant-supporting shelf. Walks also intersect the enclosed space lengthwise and across. On the surrounding stage or shelf are arranged many sorts of plants, particularly *Yuccas*, *Aloes*, *Epiphyllums*, and other succulent plants, together with a miscellaneous variety of *Ferns* and *pot-plants*. At the north end of the body of the building, a massive rock-work, built of immense boulders of stone so abundant in the vicinity, and displaying a very bold and picturesque appearance, has a fine effect. It is well clothed with the *Creeping Fig* (*Ficus repens*), *Ferns* of many kinds that yield an unfailing supply for mixing with cut flowers, different kinds of *Begonias*, particularly *B. nitida*, which rambles about everywhere, enjoying its loose position, and which blooms profusely, and *Euphorbia splendens*, which, growing in the crevices, assumes a pendent and pretty habit. A very large plant of *Monstera deliciosa* surmounts this pile of stones and earth, and, in this high position, it grows apace and is never without fruits in some stage of growth; indeed, no more fitting subject could be selected to crown the mass. At the base of this rock-work, and on its western side, is a pond, bounded by high and rugged rocks at the back, and a rocky parapet in front. Its margins are clothed with *Club Mosses* and self-sown *Ferns*, and, planted here and there, is the *Papyrus Antiquorum* or *Egyptian Paper Reed*, whose Grass-like tufted heads are very ornamental. Out of a little swampy bank in this water-basin, the white *Trumpet Lily* or *Calla æthiopica* is growing in unusual vigour and in dense clumps, now thickly furnished

with flowers. *Caladium esculentum*, and a few of the *Philodendrons*, are also serviceably employed in the decoration of this aquarium. All the rest of the space in this building is planted out in a tasteful and becoming manner, and the proportions some of the plants have attained testify greatly in favour of this system of culture as compared with that of confining the roots in pots or tubs. The Bananas form a remarkable feature here, for they are lavishly employed, and not as solitary specimens, as we commonly see them, but in the more appropriate fashion of miniature plantations of each species; and, thus treated, they confer a truly tropical aspect on their adopted home. *Musa Sapientum*, which is a tall grower, and a ready and heavy fruiter, borders the central walk that intersects the conservatory, and its massive entire leaves form a pleasant canopy or archway over the path. Several are not planted individually, as might be imagined; but those that have yielded their fruit, and begun to assume a decaying look, are cut down, and the suckers, of which there are always a more than sufficient quantity, are thus only too ready to develop themselves, and this they do in one or two years, if liberally treated. The quantity of suckers, however, is limited by thinning out the weakest; for, were all permitted to exist, they would form such an impenetrable forest, and become so weak and spindly, as almost to necessitate their entire removal and replanting before they could again be got into a satisfactory condition. When the soil becomes impoverished, as it soon does, a top-dressing of dung and loam is applied, and stimulants in the form of manure-water given, and at no season of their existence is the watering-pot withheld—hence their luxuriance. The Chinese Banana, or *M. Cavendishii*, which is the sort commonly cultivated in gardens on account of its good fruiting qualities and accommodating nature, is also here largely grown in clumps along the sides of the outer passages, and its stiff, succulent, and flourishing character makes it particularly effective amongst the other plants. The specimens of *M. coccinea*, however, of which there are some very large clumps, are certainly amongst the finest and most brilliant flowering plants in this gigantic conservatory. They are of a more spindly nature than *M. Sapientum*, *Ensete*, *Cavendishii*, &c., and are only remarkable for their flowers, which are freely produced from every stem in summer. *M. rosacea*, another beautifully-flowered species, is also here abundantly grown. The Palms, however, are more remarkable than the Bananas, considering the slowness of their growth, as the stems of many of them have here attained the dimensions of sleeper-sized timber. Perhaps the finest specimen is *Corypha australis*, which is about 50 feet high, and with a trunk-base over $2\frac{1}{2}$ feet in diameter; there are, besides, *Chamaerops Griffithiana*, *Livistona borbonica*, and several others. Of *Dracæna Draco* or the Dragon-tree, we noticed a fine tall specimen, some 20 feet high, and with a clean trunk for a considerable distance; *Beaucarnea recurvata*, about 20 feet high, with a clean stem, long pendent leaves, and very large bulb-like roots; and a specimen of *Araucaria braziliensis*, planted some yards from the north-end of the house, which had grown so tall as to necessitate its decapitation in order to prevent it from bursting through the glass roof. It has a clean and even stem, about 15 inches through at 3 feet from the base. The Aloes, planted out at the north-west corner, are in a luxuriant condition, with very thick dark green leaves from 8 to 9 feet long, and quite surpassing in health and strength anything of the kind we have observed growing in pots. Of *Fourcroya gigantea* there is a very large plant growing at the base of the rock-work, and which has lately bloomed, the flower-spike being nearly 30 feet high; but it is now bent in two, and densely laden with little young plants attached like bulbils, which, when separated and potted, at once become independent plants. Some of the specimens of the Caffre Bread have trunks over 6 feet high and 15 inches through, and a few of the Tree-Ferns are of fair size, while the Sugar Cane grows freely in the borders. Of Bamboo there is a large variety, but there are none of the large-stemmed kind seen at Kew or Syon House. *B. arundinacea* is the sort most employed, and at the southern end of the house, opposite the door, is a massive pruned archway of the same, formed of great clumps of the Bamboos planted on either side of the walk, and trained and cut into shape, and which reach to the roof. The *Hibiscus rosea*

is one of the most useful plants grown here, and of it there are large bushes that seldom or never fail to yield an abundant supply of brilliant red flowers in summer. Of the Cinnamon tree there are some large specimens thickly foliaged, which are particularly pretty when they begin to grow and produce their young leaves, which are at first of a pinkish tint. There are also good specimens of the *Adamia cyanea* coming into bloom; *Heritiera macrophylla*, or Looking-glass tree, with its large shining leaves; *Franciscea uniflora* has bushes 6 and 7 feet high, and *F. latifolia* has a large dense bush some 13 or 14 feet high, and just coming thickly into flower; *Xylophylla latifolia*, which, when in bloom, is one of the most beautiful and profuse-flowering evergreens cultivated; *Barnadesia rosea*, coming into bloom; and different kinds of *Brugmansias* in flower. There are also some very fine specimens of *Strelitzia ovata* that yield an abundance of long-lasting blooms; *Gold fussia ammeloides*, bushes of which, planted out near the walks, are about 7 feet through, and much more healthy, vigorous, dense, and floriferous, than we previously remember having seen; but the gayest of all flowers in this conservatory at this season, is the *Linum trigynum*, bushes of which are planted here and there all along the front borders, and are one mass of golden yellow showy flowers. Whether grown in pots or borders, this is one of the best of indoor winter decorative plants as well as the most easily cultivated. The *Cyanella ensifolia* is now extremely pretty, bearing dense masses of beautiful blue berries; and the *Renanthera coccinea* here clings to stakes about 11 feet high, and flowers abundantly, whilst it refuses to blossom in the Orchid-houses.

The Grounds.

Chatsworth, from a landscape point of view, has, both in the park and dressed grounds, many noble features, but still in both, especially in the former, much more might have been done. As a *confrère* of Douglas, the great Californian explorer, both being at Chiswick at the same time, one might have expected that Paxton would have done more to illustrate in the park the arboreal riches of that country; but, instead of that, you scarcely find an example of evergreen vegetation, except of the most common kind. Possibly climate may be pleaded as an excuse for this, but, when we look to the glorious examples of *Picea nobilis*, and many other *Coniferæ* in the pleasure-grounds and Pinetum, it is apparent that that plea will not hold good. The omission just adverted to is undoubtedly an oversight, and one much to be regretted. The most impressive view of Chatsworth is from the Rowsley side entrance, and, if you can catch it when the cascades and fountains are in full force, it is a sight never to be forgotten. The wealth of water as it rolls headlong through the wood from the reservoir many hundred feet above, splashing, dashing, foaming, is a sight to be wondered at, the quantity of water necessary for this purpose being, we are told, 60,000 gallons per minute. Thus associated with living waters, with splendid timber, velvety lawns, and spar-bespangled walks, Chatsworth is a fairy scene which must be seen to be appreciated. But hundreds of people who go to Chatsworth never realise its full beauty. To do so you must get away from the mansion, view it from the park and Stand Wood, and then you may get some idea of the extent of this fine ducal residence of the Cavendishes. Nor will a visit to the Stand Wood be thrown away, for there, surrounding the reservoirs which supply the fountains, will be found groves of Spruce Firs of such colossal height and noble proportions as to take one, involuntarily as it were, into a primeval forest. There is no finer sight in the gilded halls of Chatsworth than these superb trees. The main entrance from the porter's lodge to the house is margined by Tulip-trees, not of large size but in fine condition. Here, too, standing in the centre of the drive perched on a mound, is a plant of Weeping Ash, removed some forty years ago from the Mill Ash Nursery, near Derby; this, at the time, was considered a great engineering triumph, as its weight, with its many tons of earth, toll-bar gates, and other obstacles had to be removed to make way for it.

Our illustration (see p. 13) represents one of the many noble aspects of this princely mansion as seen from the right bank of the Derwent. Of the pleasure grounds, Pinetum, rock-garden, and one or two other matters of interest we shall endeavour to furnish some account next week.

THE INDOOR GARDEN.

TREE-FERNS.

(Continued from p. 527, Vol. IV.)

Cyathea.

This genus has a wide geographical range, and contains many species, some very beautiful members being yet strangers to cultivation. As a group, they are distinguished by their arborescent growth, by their veins being forked and free, and by their axillary sori. The involucre when young is entire, and completely covers the sori, but ultimately bursts, and assumes a cup-like form; this, however, is very fugacious, and, in some species, soon falls away, and, as this is one of the chief points of distinction between *Cyathea* and *Alsophila*, it often becomes extremely difficult to determine, with any degree of certainty, which particular genus an unknown plant may belong to. The various species of *Cyathea* which are at present in cultivation form splendid objects when well grown; indeed, I do not think there is a single one which is not beautiful in character. Those kinds which are natives of temperate regions, as a rule, form the stoutest stems, but even these vary much in circumference, as well as height, whilst the kinds from tropical countries are frequently more or less armed at the base of the fronds with sharp spines. As a rule, these have slender stems, which are built up rather quickly, showing large scars where the old fronds have fallen away, and which materially add to the beauty of the trunk. *Cyatheas* should be potted in the same compost as that recommended for *Dicksonias*, and should receive the same treatment.

I.—TEMPERATE-HOUSE SPECIES.

C. dealbata.—This is the "Silver Tree-Fern" of New Zealand, and is now tolerably plentiful in this country. A friend, writing to me a short time since, says, "You have neither a description nor a figure in any book in England which renders anything like an adequate idea of the rare and majestic beauty of this Fern, as I see it in my every-day walks," and, therefore, I fear my attempt to render it justice in these pages will also fall short of its deserts. The stem, as we have it sent to us, is stout and clothed with the bases of the old fronds; it is said to attain a height of 20 or 25 feet; the tallest, however, which I have seen in this country have not exceeded 11 feet, and they are seldom found so tall; the base of the fronds is unarmed, and the rachis is profusely clothed with deciduous ferruginous scales or down, which also thickly clothes the crown of the plant. The fronds are from 4 to 10 feet long, or even more upon well-developed specimens, and bi-pinnate; the pinnules narrow and deeply pinnatifid on the upper side; they are dark green, but of the brightest silvery-white underneath, a character which at once distinguishes it from all others, and adds so much to its beauty. It seems to be quite peculiar to New Zealand.

C. princeps.—A truly majestic plant, usually grown in the stove; but, having seen it succeed for several successive seasons in a cool conservatory, I can conscientiously place it in the list of temperate-house kinds, and thus those who do not possess a stove, may, without hesitation, introduce it into their greenhouses. The crown of the plant, base of the fronds, and also the rachis, are densely clothed with a profusion of large white or ash-coloured chaffy scales. The bases of the fronds are quite unarmed and very stout. The fronds in young specimens are some 2 or 3 feet long, but on fine old plants reach a length of 12 or 14 feet. They are tripinnate, and bright green in colour on the upper side, but below almost glaucous. The grand beautifully-arching fronds of this fine species cannot but elicit the admiration of all beholders. It was first introduced into our collections under the erroneous name of *Cibotium princeps*, and, indeed, is still to be found in many gardens so named, but, having produced fruiting fronds, its correct relationship has been determined. Native of Mexico.

C. Burkei.—This plant has been recently figured in THE GARDEN, and it will eventually prove, I am sure, the most beautiful species in the whole family. I have recently seen this plant in some quantity at the Victoria Nursery, Upper Holloway, and all lovers of Tree-Ferns have much need to thank Mr. Williams for having introduced to commerce this truly beautiful plant. It forms a stout erect stem, and the manner in which its splendid fronds sweep downwards as they unfold renders the name of the Weeping Tree-Fern peculiarly applicable. The stipes are very dark in colour, rough at the base, with numerous very short blunt spines or tubercles, and profusely clothed with large shining brown chaffy scales. The fronds are bipinnatifid, from 2 to 4 or 5 feet in length, and bright green in colour. Native of South Africa.

C. Dregii.—Some few years ago I had a small plant of this species; which, however, made but little progress, and it was not until I saw it at Mr. Williams's, upon stout stems, that the beauty of this plant was discernible. It is very distinct from the preceding

species. The fronds are bipinnate; pinnules, pinnatifid, dark green above, rather paler beneath; stipes, reddish-brown, and somewhat sparingly clothed with reddish-brown chaffy scales. Native of South Africa.

C. Smithii.—A very handsome and rather rare plant in collections. Although I have included it here amongst the temperate-house kinds, I have invariably found it to succeed best with a little extra heat during winter. The stems are somewhat slender, and very elegant, attaining a height of about 20 feet, the crown of the plant and the stipes are profusely clothed with bright reddish-brown chaffy scales. The fronds are beautifully arched, and from 6 to 10 or more feet in length, twice or thrice divided. The segments being delicately cut, and the shade of green being peculiarly cheerful, tend to render this an extremely handsome member of the genus. Native of New Zealand.

C. medullaris.—This is a strong vigorous-growing and handsome plant, and, if space can be afforded it, will soon produce a splendid effect. In its native country the aborigines seem to make a dainty dish of the crown and inside of the stout stipes; it is very questionable, however, if the New Zealander, who is to take his seat on London Bridge and view the ruins of this city, will not even then be able to find here a more palatable dish. The stems are rather stout, attaining a height of from 20 to 30 feet; the stipes and rachis are black, the former slightly muricated, and these, as well as the whole of the frond before it unfolds, are completely enveloped in large black chaffy scales. The fronds are bi-tripinnate, and from 10 to 15 or 20 feet long; the pinnules leathery in texture, and deep green in colour. Native of New Zealand, but not peculiar to that country as most of its Ferns are.

C. funebris is a plant of somewhat recent introduction in our collections. Very little can, therefore, be said by me respecting it. The stem is stout and dark-coloured; the fronds broad and massive, leathery in texture, and dark green. It is very handsome in a young state, and entirely different from the preceding species, although it would seem to have many features in common with it. Native of New Caledonia.

C. Cunninghamii.—Our illustration of this extremely rare Fern was taken from the unique specimen in the rich collection of Mr. Williams, of the Victoria Nursery. It is a very handsome species, and as rare as handsome, for all the stems which I have seen offered for sale have been those of *Alsophila capensis*, a proof that this plant is little known and understood. Young plants of it are very rare, but well deserving the attention of Fern-growers whenever they can procure it. The stem is medium-sized, and gives one the idea of the plant being mid-way in its relationship to *C. Smithii* and *C. medullaris*. The stipes are slender and black, adhering to the stem like those of *Dicksonia squarrosa*; their base is slightly muricated. Fronds, tripinnate, finely divided, and feathery in appearance, from 5 to 10 feet long, and bright green in colour. Native of New Zealand, but, as far as I can ascertain, by no means common even in a wild state.

II.—STOVE SPECIES.

C. canaliculata.—We now come to those which are natives of tropical climes, and I have chosen to begin the enumeration with a species at once extremely beautiful, extremely rare, and extremely limited in its distribution, and which should, therefore, be the more highly prized by those who may be the happy possessors. It is not a very large-growing kind. The stems are only moderately thick, or they may, perhaps, be better described as rather slender, and very dark-coloured; stipes, black, unarmed, but densely clothed at the base with large, dark chaffy scales; fronds, bipinnate, and coriaceous in texture, from 5 to 8 or 10 feet in length; pinnules, very broad and deeply pinnatifid, from 8 to 10 inches long and upwards, of 2 inches broad, intensely deep green on the upper side, but much paler beneath. The sori are large and very ornamental. Native of Bourbon, Mauritius, and Madagascar.

C. arborea.—A majestic plant, attaining a height of from 20 to 30 feet, and bearing a large crown of beautiful plume-like fronds some 12 feet long. These, however, are only its dimensions at its greatest size. Handsome young trees exhibit all the grace of the old ones, with all the measurements considerably curtailed. Stem, slender, unarmed; the stipes, however, have a few short blunt spines at the base; these, together with the crown of the plant, being clothed with large white chaffy scales. The rachis is also furnished with smaller scales, of the same colour, for some considerable distance up. The fronds are from 3 to 6 feet long, and, upon old well-developed specimens, attain a length of even 12 feet. They are broad, plume-like, twice or three times divided, and arch over in a very graceful manner; pinnæ, from 1 to 2 feet long, the pinnules being very finely divided, and vivid green on the upper side, paler below. It seems to be abundant throughout the West Indian Islands.

C. Imrayana.—A somewhat rare plant in collections, independent

of which, however, it is very elegant; stem, slender; the bases of the fronds are armed with short prickles, and, as these adhere to the trunk for a considerable time, they give it the appearance of being spiny; crown of plant and stipes clothed with large ferruginous chaffy scales; frond, twice or thrice divided from 3 to 6 and 12 feet long, and bright green. It varies considerably in the breadth of the pinnae and pinnules, but all the varieties are beautiful. Native of Jamaica, Dominica, &c.

C. aculeata.—This is another of the slender-stemmed West Indian species, the base of the fronds-stalks being furnished with numerous short prickles; crown of plant furnished with brown chaffy scales; fronds, from 3 to 6 or 8 feet long, broad and handsome, bipinnate, the segments being furnished beneath with a few short hairs. It is a very handsome species, but does not appear to produce a very large crown.

C. serra.—A truly beautiful and massive-looking species, attaining some 20 or 30 feet in height; the stipes are stout at the base, furnished with a few short blunt spines, and densely clothed with very large chaffy scales, as also is the whole crown of the plant; the fronds are twice or thrice divided, long, broad and deep green in colour. Native of the West Indies and Caracas.

C. excelsa.—This beautiful and rare species is often confounded with *Alsophila excelsa*, but no two plants can be more distinct. The species in question forms a somewhat slender dark-coloured stem, bearing a grand head of rich deep-green fronds, which are twice or thrice divided, the chief divisions being from 1 to 2 feet long, or even more on finely-developed plants. It seems peculiar to the islands of Mauritius and Bourbon.

C. integra.—It is a remarkable fact that very few species of Tree-Ferns from the East have, up to the present time, become established in our collections. This one, however, is an exception, and, although acquainted with it only in a young state, I shall be only within the bounds of moderation when I say that it bids fair to rival any of its Western relatives. The stipes are unarmed; fronds, broadly-lanceolate in outline, twice or thrice divided; the segments broad and deep-green. It is a rare plant in cultivation. Native of the Philippines.

C. Hookeri.—This is an extremely elegant little species, and very rare in cultivation.

It forms a slender stem; but I know nothing of it, saving in a young state. When seen fertile, it may prove to belong to *Schizocæna*; but this is only conjecture on my part. The fronds are pinnate below, pinnatifid towards the apex; the rachis is, however, winged nearly to the base; lower pinnae, obtuse, upper ones longer and more acuminate, slightly serrate at the edges; colour, bright green; the base of the stipes is furnished with a few black chaffy scales. The fronds of this truly elegant species are somewhat membranous in texture; and, consequently, it requires the atmosphere to be well charged with moisture, and should be kept well shaded. I have been told that, during the dry season in tropical countries, all such plants have their fronds shrivelled up, and very little is seen of them, and that my practice of keeping Ferns watered and growing in winter is a mistake; but, as it is the fashion to want Ferns in a healthy-looking state summer and winter, and, moreover, as the plants thrive admirably under this régime, I can see no use in killing in winter that which has been produced during summer. I would rather endeavour

to preserve the fronds upon the plants as long as possible; for, by so doing, a far better display is made, and the plant or plants rendered more ornamental. Native of Ceylon.

C. microlepis.—I have neither found this name nor plant anywhere, saving in German gardens, so that of the correctness of the name I am not certain, but of its beauty there can be no two opinions; the fronds are long and broadly lanceolate in outline, tripinnate; pinnae, 18 inches long, the segments being somewhat falcate and obtuse, the upper side is dark green, but beneath they are clothed with a quantity of small scales, which give it a somewhat ferruginous aspect; the sori also are very peculiar, being apparently confined to the vein next the mid-rib of the pinnules; the stipes and rachis are both furnished with prickles. It requires the temperature of a stove, but I am totally unacquainted with its native country.

C. muricata.—This is a magnificent plant, although I have not seen it large in this country. Specimens now before me show the

fronds to be bi-pinnate with the segments deeply divided. The pinnae are from 12 to 18 inches long, and oblong-acuminate in shape, the segments being obtuse and crenate at the edges, deep green on both sides, the upper being, however, the darker. The stipes and rachis are armed with short prickles. It carries a beautiful head of dark green plume-like fronds, which renders it very attractive. Native of the West Indian Islands.

C. Schanschin.—Stipes and rachis armed with short spines; fronds, long and bi-pinnate; segments, linear oblong and obtuse; very slightly crenate, deep green above, slightly paler below. There is something in this plant which strikes one that it is distinct, and yet its characteristics are difficult to define; nevertheless it is very handsome, although I fancy somewhat rare. It seems to be a common species throughout tropical America.

C. nigrescens.—This is at once a very massive, distinct, and beautiful plant, unfortunately very rare in collections. Indeed, the true plant would seem to be very little known. The stem is somewhat stout, and, together with the frond-stalks, armed with very stout black spines; fronds broad and massive-looking, twice or thrice divided; pinnae, from 12 to 15 inches in length; pinnules, deeply pinnatifid, segments obtuse, very deep green on

the upper side, paler below. It is a grand species, and very distinct amongst a collection of arborescent kinds. Native of Jamaica, &c.

(To be continued.)

G.

Cyathea Cunninghamii,

NEW VARIETIES OF CALADIUM.

THE following varieties, raised by M. Bleu, an eminent Caladium grower, and exhibited this summer at Paris, are described and highly spoken of by M. E. André, in the *Illustration Horticole*:—

Onslow.—Plant, small-sized; centre of the leaf, blood-red, as in *C. bicolor*; margin, green; surface dotted with white, shaded with rose-colour.

Lepeschkinei.—Leaves, convex, slightly larger on one side, as in the variety *Ed. André*, but finely marked with vivid red, especially on the veins.

Emilie Verdier.—Plant, strong and tall; leaves, small, hastate, half rose-colour and half white, veined with brilliant dark green.

Felicien David.—A very vigorous plant. The heart-shaped

leaves are borne horizontally, and have very large basal lobes; margin green, centre white, with strong radiating veins of a carmine-lake colour.

No. 1.—Plant, vigorous; leaves, green and white, with a broad network of handsome green, and veins of a deep blood-red colour.

No. 2.—A hybrid, between Leplay and Ad. Bleu; leaves very large, of a charming transparent rosy-white colour.

No. 5.—Leaves very numerous, opaque, white; principal veins of a fine vivid carmine.

No. 7.—A very remarkable hybrid, between Marquise de Cazeaux and Triomphe de l'Exposition; leaves of a brilliant crimson in the centre; margin deep green; veins crimson; surface marked with very white spots. All the shades of colour fine.

No. 16.—A hybrid, between the Duc de Ratibor and bicolor fulgens: leaves white, with a green margin; centre perfectly translucent, and of a charming rose-colour; veins, delicate rose.

No. 13.—A hybrid, between Belleyme and Ch. Rouillard; leaves elongated, rather slender, of medium size; centre white; margin green, with stripes and network of the same colour; veins of a deep blood-red.

CŒLOGYNE CRISTATA.

THIS chaste and beautiful plant is certainly the queen of cool Orchids, and was introduced by the distinguished plantsman and traveller, Hartweg, who found it in woods near Guatemala la nueva, a province in Mexico, possessing a very equable temperature (the maximum rarely exceeding 80°, and the minimum 60°). Coming, as it does, from this temperate region, it is surprising that many cultivators adopt a high temperature in its cultivation. I have at this moment two specimens bearing respectively 160 and 230 pseudo-bulbs, upon each of which is a fine robust spike of flowers. Opening at this season, they are invaluable for all purposes where chaste and refined flowers are required. My plants have been grown throughout in an ordinary Mexican house, where the temperature rarely rises to 60°, except during the hot summer months. During the autumn, the plants stand in a cool Vinery or similar place, and are not introduced into artificial warmth till the middle of November, when they are placed in the cool Orchid house, and kept at a temperature ranging from 50° to 55°, in which they now (Christmas week) commence to expand their lovely dove-like blossoms. As soon as they have done flowering, they are re-potted, or the roots examined, and supplied with a little admixture of fibrous peat, leaf-mould, and Sphagnum, chopped very fine, and silver sand. They are then well watered and kept in the same temperature till the summer months, when they are comparatively dried and exposed to the vicissitudes of weather we usually have during the autumn months, merely receiving the shelter of the house they stand in. There is no plant I am acquainted with more easy to manage, and, were we to receive each introduction *ad libitum*, as in the case of many Orchids, we should find this queen of the Guatemalan forests reigning in every British garden in which Orchids are cultivated to any extent.

The Nurseries, Epsom.

RANSLEY TANTON, F.R.H.S.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Double-flowered *Lilium auratum*.—At a meeting of the Central Horticultural Society of France, held on the 11th of last September, M. Duchartre read a letter from M. Boisgiraud, of Tours, in which that gentleman stated that, amongst the plants of *Lilium auratum* in his garden, one had produced double flowers. This makes the fourth species of Lily which has produced a double-flowered variety, the others being *L. tigrinum*, *L. candidum*, and *L. Thunbergianum*.

***Agathæa celestis variegata*.**—A friend of mine sent me a plant of this last spring, growing in a large 60 pot, and I placed it in the conservatory, and allowed it to flower during the summer. It was thoroughly pot-bound, and it bloomed freely. It has now quite a charming appearance; it has made a dense wiry growth, the leaves are prettily variegated or marbled with cream and green, and it is beginning to flower again from the points of the shoots. It appears to be almost, perhaps quite, hardy, and I think it will yet prove a useful plant for winter decoration.—R. D.

Plants for Forcing.—We have many plants suitable for this purpose well known for their value as early bloomers, and there are doubtless many others well adapted for spring forcing if tried. Of these, *Saxifraga crassifolia* is one, while only the other day I saw some fine pots of *Scilla siberica*, covered with their beautiful blue flowers. The scarlet-flowered *Schzostylis coccinea* blooms well in the conservatory during the winter season, and deserves growing for the last-named purpose. Doubtless further experiments with some of our hardy herbaceous plants would furnish many admirable subjects for early bloom. One of the best of all plants for spring forcing is the rosy-flowered *Dielytra spectabilis*, and its white-flowered variety, although rare, is also very attractive.—J., *Whalley Range*.

THE FLOWER GARDEN.

SWISS FLOWERS.

No Canton in Switzerland, probably, can boast of rarer flowers than the Valais, unless it be the Grisons: and of all the glacier streams, none waters a richer flower valley than the Visp river, as it rolls on to join the glorious Rhone. I purpose ascending the river to Zermatt, thence to its source in the ice-caves under the Riffel, onwards to the glacier that stretches so silently under the Matterhorn, and Monte Rosa; and I shall gather as I go some of the rarities often scattered by Nature with no unsparing hand. Many of your readers will be able to follow me in my explorations; others may be induced to do so, some coming summer. I shall simply enumerate the rarer flowers, whether Alpine or otherwise, that, amid many treasures, more especially attracted my attention. Soon after passing the village of Stalden, a yellow Vetch, with a solitary yellow flower and square seed-pod, peered out from among the Grass on the bank—it was *Tetragonolobus siliculosus*. The narrow road was bordered by a Milfoil that bore a strong family likeness to our own *Achillea*. My Swiss Flora soon revealed its name; it was *Achillea dentifera*, of slimmer habit than ours. Among a *débris* of rocks I recognised a yellow Rest-harrow: there could be no mistake about it. Its glutinous stems and veined petals spoke for it. I found it was *Ononis Columnæ*, and local in its distribution. Near it I noticed *Asperugo procumbens*, and a curious *Centaurea*, which proved to be *maculosa*. On passing St. Nicholas, the half-way house as it is called, I gathered an old garden friend (*Lychnis Flos-Jovis*), with its woolly-leaved stem. This flower occurs also in the Grisons and Tyrol. Just as I reached Zermatt, I noticed a pretty blue Lettuce, with leaves cut like the Endive, growing in crevices of the rock. It was *L. perennis*, and it might be introduced into our rock-gardens with good effect. Before ascending the Visp above Zermatt, we must make a *détour* to the right and explore the Trift Glacier and its surroundings. As we ascend above the little English church, we gather *Bupleurum ranunculoides*, with its grassy leaves and little umbels of flowers, reminding you somewhat of *Astrantia*. Near the cleft, through which the glacier waters come rolling down, is a beautiful white Lily-flower (*Anthericum Liliago*) growing in wild craggy ground in company with *Campanula spicata*, another of our Tyrol plants, with blue and sometimes dingy white flowers. We have now arrived at the gorge, and crossed the wooden bridge over the roaring waters below. Here the truer Alpines begin to put in an appearance, but not as they do on ascending to the Riffel. Still there is enough to interest one: an unrivalled bed of the Glacier flower (*Leontopodium*), as it never grows on our rockeries, but covered with its felt dress; *Kernera saxatilis*, close to the edge of the glacier torrent; beautiful *Linaria alpina*, with its glaucous leaves, and Nature's strangest harmony of colours in the corolla, purple and orange; another Crucifer, *Draba Traunsteineri*, peeping out from under a ledge of rock, with its cousin *Draba frigida*. A little further on, under a similar ledge, is *Saxifraga aspera*, whose leaves are like little saws. The Trift is well worth a visit, if the narrow gorge will allow of your going high enough, and your nerves are strong enough to endure the tumbling of the glacier-waters. But we must now ascend to the flower-land of the Alpines, which we so love to torture into cultivation in old England! Here we revel in a very Eden of Alpines. I know not which first to gather, perhaps *Lloydia serotina*, as it is a reputed British species. Well, the little gem grows as Daisies do in England in some parts of the ascent. I got up several of its tiny bulbs; it was such a lovely Lily-bell. All around you are those prettiest of the Primulaceæ, the *Androsaces*. At least half a dozen kinds greet your eye. And two of these are *A. carnea* and *A. glacialis*, with their cushions of Lilac contrasting with the blue of the bluest Alpine Forget-me-not (*Eritrichium nanum*), the gem of Pitz Languard in the Engadine. But I must not omit another Alpine I never saw in this country, the local *Aretia Vitaliana*. This is one of the Primrose tribe. He who would grow it well must plunge it in its own granite silt. Which must I tell of next? *Campanula cenisia*, or *Phyteuma humile*, or the cushion-like tufts, all flowers, of *Thlaspi*

rotundifolium—or *Saxifraga oppositifolia*, which so often disappoints us on our rock-work after seeing its purple masses in the Alps. Then again, fancy the mountaineer, *Astragalus aristatus*, brought away to dwindle in the plains. This is a glorious plant in its home, high up in the mountains. Time and space would fail me to tell of *Anemone baldensis*, *Phyteuma Halleri*, *Soldanella Clusii*, *alpina*, and *pusilla* peeping through the snow; *Gentiana utriculosa*, *Phaca frigida* growing in the upper pastures where the highest châteaux are built, *Paradisica Liliastrum* fair as its name—so I must stop and promise you a ramble through the Engadine if you are not already tired of the long walk I have taken you.

The Lodge, Hovingham, near York. PETER INCHBALD.

THE GREAT THRIFT.

STATICE PSEUDO-ARMERIA, otherwise known as *Armeria*

cephalotes, of the "Hortus Kewensis," is unquestionably the most gigantic representative of the Thrifts or Sea Pinks. Of these two trivial names the latter is by far the most appropriate. The true normal habitat of all the species of this family is on the sea-shore or the margins of our large tidal rivers, where they luxuriate in the adjacent saline swamps, becoming so far impregnated with saline matter as to possess a brackish taste. Though, as I have stated, the sea-side is its normal habitat, yet it possesses, like other littoral plants, a tolerably cosmopolitan character, and is not unfrequently met with on the summits of some of our loftiest mountains, where, doubtless, it bears a certain, though undemonstrative, testimony of the change that has taken place during by-gone ages in the relative land and sea levels. The name Sea Pink is appropriate for two reasons—one of these will be obvious to any one who has seen the lovely roseate hue given to the shelving ledges of our sea-coast, where the common *Armeria vulgaris*, the species with which, in this country, we are most familiar, flourishes. Another is indicated by its generic title *Armeria*, which was the classical name of the Sweet William before the Knight of Normandy, whose name it bears, had essayed to tread the rosy carpet which is so characteristic of our shores. That botanists have made a happy distinction in separating the Sea Pinks from the Statice, popularly known as the Sea Lavenders, will be disputed by no one who is familiar with the characteristics of the two plants. Setting aside all the minute technical distinctions, which are neither few nor unimportant, the uneducated eye would have much greater difficulty in understanding the similarity than the more obvious dissimilarity in outward appearances that is presented by the respective genera *Statice* and *Armeria*, or to use common English parlance, between Sea Lavenders and the Sea Pinks. Of all the species of *Armeria*, and they are not few, there is none more showy than that represented in the accompanying figure of the true *Armeria cephalotes*. Be it noted that I here use the term true advisedly, for, so subject are the species

The Great Thrift.

of this genus to hybridisation and variation that the cultivating of many species in close juxtaposition leads to such an indiscriminate blending of the specific characters as to place the descriptive botanist in a mental atmosphere very little better than a London fog. Where specific variability is so prevalent it will not be at all surprising when I say that the colour itself varies, in the species here represented, from pure white (somewhat rare) to a deep crimson-pink. The large heads of bloom supported on slender stalks, from 15 to 20 inches in length, when over-weighted by the moisture of a passing shower, are liable to claim too close an acquaintance with mother earth—and more unshakeable plants there cannot be—still supports are necessary, and, seeing that a single stake and tie of matting is the gardener's usual solution of the difficulty, and that such a mode of support is essentially ugly and unnatural, it behoves me to suggest some more effective mode

of dealing, not only with this plant but with many others of a similar character. With this end in view, I know of no more effective arrangement than the following:—Take a Hazel rod, say $\frac{1}{2}$ inch diameter, cut it into lengths of 12 or 15 inches each, square across at one end, pointed at the other; then take lengths of galvanised iron wire, say 15 inches each, bend one end at right angles, about 1 inch, and hammer the same into the flat end of the Hazel stake, then bend the other end into a circle about four inches in diameter; having previously doubled the other end in form of a short hook, which will readily close on to the end, let into the upright stake, thus forming a girdle about 4 inches diameter, which will encircle the flower stems about 9 inches above the ground level, and thus support them without any stiffness of contour. Permit me to remark, that the same mode of support by enlarging the wire cincture may be used with advantage, for many of the dwarf-growing herbaceous plants, and especially so for Pinks and Carnations, and other plants of the same typically slender-stem formation, where individual stem-staking would be almost impracticable. The *Statice Pseudo-Armeria* is a native of the South of Europe, and, though generally considered a distinct species, is looked

upon by some as a large form of the old *Statice plantaginea*.

J. C. N.

ALPINE PLANTS AT BENTHALL HALL.

By J. C. NIVEN, Botanic Gardens, Hull.

(Concluded from p. 477, Vol. IV.)

I do not think that I can pay a higher compliment to Mr. Maw's gardener, on whom the detail of staking and tying must necessarily devolve, than to say that, though neatness and trimness were visible through the whole collection, the staking, or the mode by which the plants were supported was scarcely ever to be seen, or at least never obtruded itself on my observation. All the plants, though amenable to certain cultural laws, were

allowed such latitude that their natural character was well exemplified; nor should this fact pass without receiving its full modicum of appreciation, seeing that we more often meet with an infringement of Nature's laws than the reverse; as an illustration, during my ramble in the south I saw an instance of the beautiful Campanulaceous plant, *Symphandra pendula*, whose true position is on a ledge of rock, with its flowering branches hanging pendulous, in character with its very appropriate specific title, just reversed and carefully tied to a very thick stake, its large cream-coloured flowers gaping upwards as though they were bells that had lost their tongues, and were silently beseeching to be relieved from their upright bondage; nor is this, though a marked example, by any means a solitary one.

The mode by which the individuality of plants, as regards their nomenclature, is maintained is a point of so much importance, whether the collection be small or large, but especially so in a collection of 5,000 or 6,000 species as we found here, that it behoves me to make a remark or two concerning it. Messrs. Maw's terra cotta labels have a wide reputation, and as would naturally be expected, their services are here called into requisition. As used here, they consist of labels about 6 inches long by 1 inch wide; on these the name is neatly written and burnt in, so as to be perfectly indelible; and here is a most important advantage—the tally may be absolutely buried, without in the least degree affecting the legibility of the writing. In my opinion, an increase in length, and also slightly in width, would be an advantage; but possibly this has been regulated by the practical experience acquired in dealing with a material of a somewhat brittle character—the greater the size, the greater the risk. One very important item, which occurs on the lower end of each tally, and which is only visible when the information is required, consists in certain letters, which indicate the source from whence each plant has been obtained. This, bearing in mind the diversity of nomenclature that still exists, and will ever exist amid a host of synonyms, is information not by any means to be despised, and but too rarely chronicled. Though in public collections, such as those of botanic gardens, small labels would be almost useless, they answer all purposes in a private collection, and with their use the usual churchyard appearance that a herbaceous ground presents during the winter time is altogether obviated. Mr. Maw has some nice span-roofed pits with the interior sunk some 15 inches below the ground-level, which are invaluable for growing many of the rarer plants; and here we find pans in use that for general Alpine culture have everything to recommend them, if we omit the matter of cost. These are made with double sides, giving a space of about half an inch between the outer and inner skin, which space, during the summer time, is filled with water, and offers two most important advantages. First, the roots are kept moist and cool; and whoever has delved his fingers into a mountain bog on a hot summer's day, to lift a fresh-found floral treasure, will readily appreciate the value of such conditions, even though artificially obtained; secondly, the water surface forms a glorious protective cordon against slugs—those double-distilled pests, which all cultivators of Alpines will cordially unite in denouncing. I might here suggest the utility of pans so constructed for rearing seeds generally, but more especially for those of Alpine plants such as Primulas, Gentians, Soldanellas, the more choice Saxifrages, &c., in fact, all those seeds that do not vegetate till the second year. The reason will be obvious to anyone who has had to deal with such seeds, but to those who have not had an opportunity of acquiring that experience which practice gives, I may explain, that, under ordinary treatment, the continuous watering on the surface, during the long summer, lays the seeds bare, and, if vegetation during the latter part of the first season should take place, the early embryonic development is too often "nipped in the bud," and hundreds and thousands of seeds and, under favourable circumstances, ultimate plants perish. With pans constructed as I have above described, the whole body of the soil may be retained in an equable state of moisture, without a particle of surface moisture, merely by filling-up with water the cavities between the two skins, which may be readily done with a small narrow spouted can. The material of which all garden pots is made is essentially porous,

and so long as the space is filled with water so long will the body of the soil on which the seeds are placed retain an equable state of moisture, anything like sourness being checked by the perfect drainage, which is maintained in the usual way; the alteration in the character of the sides does not, in the least, affect the ordinary arrangements made for this purpose in the bottom of the pots. I might, and perhaps ought to, bring my short sketch of Benthall Hall to a close with a list of the more showy plants in bloom on the occasion of my visit; but as it occurred so late in the season, any such list would give but a faint idea of the extent and interest of the collection here cultivated. I have, therefore, thought it better to record generalities rather than details, and will bring my remarks to a close by saying that, in everything about the place, neatness, order, and method are visible to a degree rarely met with in gardens, and when met with worthy of the highest appreciation.

Hardy Plants in Flower.—The following were in bloom at Salvington, near Worthing, on Christmas Day, viz.:—*Anemone sylvestris*, *Lobelia speciosa*, *Veronica decussata* and *lanceolata*, *Valeriana alliarifolia* and *asarifolia*, Candytuft—White Rocket, *Gazania splendens*, *Nasturtium*, *Calceolaria*—yellow and dark, *Pyrethrums*—three varieties, *Primula acaulis flore pleno*, lilac and white, *Geranium nodosum*, *Echeveria secunda glauca*, *Silene Schaftii*, *Roses* (Tea)—various, *Stocks*—Scarlet East Lothian, Queen Brompton, and purple Queen Brompton; *Agathæa cœlestis*, *Violet Czar*, *Malva crispa*, *Godetia Whitneyi*, *Lupinus subcarnosa*, *Ceanothus americana*, *Antirrhinums*—various, *Chimonanthus fragrans*, *Escallonia macrantha*, *Berberis Darwinii*, *Ligustrum japonicum*, *Garrya elliptica*, *Mignonette*, *Vinca major*, *Myosotis dissitiflora*, *Omphalodes verna*, *Lavender*, *Marigolds*—common, *Wallflowers*, *Pansies*, *Aubrietia purpurea*, *Daisy*—scarlet, *Schizostylis coccinea*, *Coronilla glauca*, *Genista fragrans*.—F. T. GADD.

— At Wardie Lodge, Edinburgh, the following were in blossom on the 25th ult., viz.:—*Arbutus*, *Laurustinus*, *Ivy*, *Garrya elliptica*, *Desfontainea spinosa* (one flower), *Erica carnea* and others, *Rhododendron dauricum*, *R. atrovirens*, seven herbaceous *Asters*, *Feverfew* (single, double, and rayed), *Achillea aurea*, *Cardamine rotundifolia*, *Arabis procurrens*, *Aubrietia* (Belvoir seedlings), *Violas* (Dickson & Co.), *V. odorata*, *Anemones* (single red and white), *Hepaticas* (single, red, blue, and white), double *Daisies*, *Roses* of different sorts, *Chrysanthemums*, *C. frutescens* (yellow and white), *Myosotis dissitiflora*, *Primulas* (*Auricula*, *Polyanthus*), fifteen varieties, *Oxlip Primrose*, six do. *Helleborus* (*H. abchasicus*), *Tritoma grandis*, *Campanula*, *Potentilla*, pot *Marigold*, *Tussilago fragrans*, double *Colchicums*, *Carnations*, *Jasminum nudiflorum*, *Phlox* (autumn-flowering), *Mignonette*, *Stocks*, *Wallflowers*, *Snowdrops* showing colour, scarlet *Pelargonium*, *Calceolarias*, *Salvia fulgens*, *S. variegata*, Sweet-scented *Geraniums*, *Balm of Gilead*, *Sweet Verbena*, *Agathæa cœlestis*.—F. J. HOPE.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Tree Heath (*Erica arborea*).—We have seen plants of this very hardy Heath during the past week in full bloom in Messrs. Lee's Nursery at Feltham, and cannot but wonder that it is not found in abundance in our flower markets during this period of the year. It is, without doubt, one of the most charming hardy winter blooming plants we have, both for house decoration, for the open border, or for cutting from for bouquet or table uses.

***Ranunculus asiaticus*.**—I should like to know whether the single variety of this *Ranunculus* is in cultivation or not. It is said to be abundant in the neighbourhood of Jerusalem. There is a figure of it in Sibthorp's "Flora Græca," and in the "Theatrum Floræ" are figures of three sorts, the white, the scarlet, and the yellow. I have never seen it, but I should think it would be a desirable addition to hardy spring-flowering plants.—H. N. ELLACOMBE, *Bitton Vicarage*.

***Polygala Chamæbuxus*.**—This valuable winter-blooming plant is just now covered with buds, which will burst into flower in a few days. It is perfectly hardy, is evergreen, and grows in a continuous spreading manner. It does not exceed 3 inches in height, and it propagates itself with great rapidity. The flowers are pale yellow. It makes a capital edging plant for shrubbery borders, but needs to be occasionally lifted in order to keep it within bounds. Nice rounded tufts of it lifted and potted up early in winter, are very useful in a cool greenhouse or conservatory when other blooming plants are scarce.

***Myosotis dissitiflora*.**—Strong seedling plants of this early spring flower are already bursting freely into bloom in the open ground, at least a fortnight earlier than propagated plants, and they are far more robust in growth. I have planted out about 1,000 of each on a warm south border, and shall thus be able to give the two forms of plants a fair trial, but present appearances are largely in favour of seedlings. These were raised from seed sown in boxes under glass early in July, and were transplanted to the open ground at the end of August. The bulk of them are now 6 inches across, and they have seven or eight points, all of which are showing bloom. Such plants as these lifted into 32-sized pots now, and placed in a cool house, would soon be a mass of flower, and make lovely ornaments for any place or position.—A. D.

CHATSWORTH FROM THE RIGHT BANK OF THE DERWENT. (See p. 7.)

THE ARBORETUM.

THE CULTIVATION OF THE SCOTCH FIR AND ITS VARIETIES.

By WILLIAM GILCHRIST, Oluny Castle, Aberdeenshire.

The Pine is king of Scottish woods,
And the queen, ah! who is she?
The fairest form the forest kens,
The bonny Birken Tree.

It is considered probable by some writers, that in early ages the greater part of Britain, with those islands towards the north, in which there is now hardly a shrub, were covered with Pine forests. The remains of Pines are still found in the peat bogs of the northern counties, so much so, that Pine roots form an article of commerce, not only in the villages near which they are found, but also in the principal towns. It would be interesting to consider these ancient Pines historically, and endeavour to form some idea as to what climatic changes our country has undergone since the time when they luxuriated in situations where it is now almost impossible to grow them; but the subject being "the Scotch Fir, its cultivation and varieties," the following remarks must be devoted to the consideration of the present instead of the past. To make this report as concise as possible, we will consider it in the following order:—1. The descriptive character of the Scotch Fir, and the varieties most adapted for use and ornament.—2. The soils and situations where found growing, and best suited for proper development.—3. Cultivation and value at different periods of growth.—4. The purposes to which it is applied in the arts and manufactures.—5. The diseases to which, as a forest tree, it is most liable.

The Character of the Scotch Fir (*Pinus sylvestris*), and the varieties most adapted for use and ornament.

There are many specified varieties, but most are only cultivated for variety's sake. These are chiefly produced by cultivators, and can scarcely be called specific. Botanists are agreed as to one variety, and, when they agree, the cultivator's opinion can only be regarded as a theory. G. Don, of Forfar, tried to prove that there are at least two varieties; but Grigor, of Forres, an equally good authority, maintains, that though there is variety, it is the result of degeneracy, and that the alleged varieties do not keep their distinctive character at all stages, and fail to reproduce themselves. The author of "The Forester," another close observer, seems to declare in favour of Grigor's theory. Granting that there is only one distinct variety, and that other differences in appearance are only sports, or the result of degeneracy, or the exhaustion or unsuitableness of the soil, we have still to account for the quality of timber, which is often, in the natural forests, different in two trees growing side by side—the wood of the one being white, soft, and brittle; and of the other, resinous, tough, and durable, with full-developed heart-wood. The cones of the former are longer and more tapering towards the point than the other, and are so distinct that a practised eye at once distinguishes them, and yet the one often produces the other. The same phenomenon occurs with other trees, and if a few distinct specimens would constitute a variety, they could be had in any number. We grant that there are variations in leaves, cones, bark, wood, and general character, but as these fail to reproduce themselves, and are more or less affected by soil, situation, age, &c., we conclude that they are not specific varieties. However, there are several varieties cultivated whose distinctive characters are maintained by propagation, and were attention directed to this point, any number of varieties might be got. The most distinct of this class are the *Pinus sylvestris aurea* and *argentea*, both robust, compact, and ornamental. They are both the production of Messrs. Dickson and Co., Perth Nurseries, but the slow and uncertain means of propagation prevents their coming into general use. This is not to be regretted, as their proper place is the lawn or Pinetum in single specimens or small groups. It is doubtful if they would ever equal the common Scotch Fir as a useful tree, even if they could be produced at the same rate. The *Pinus sylvestris hagenensis*, common on the continent of Europe, and extensively used in Britain as a nurse for hardwood trees, &c., may be noticed as a special variety, and a rapid grower; but as "attention is particularly directed to the selection of any special variety adapted for use and ornament," we at once cast in our lot for the *Pinus sylvestris rubra*, as we consider it to be that from which all the other so-called varieties have sprung, and the only one adapted for use and ornament combined. Its character, according to Loudon and Don, is thus given:—Leaves, from $1\frac{1}{2}$ to 3 inches long, generally in pairs, stiff and twisted, of a pale green or glaucous colour, concave on the upper and convex on the under surface, serrulated on the edges, but not marginated; buds, ovate, blunt pointed, $\frac{1}{4}$ to $\frac{1}{2}$ inch long, and $\frac{1}{4}$ inch wide at the broadest part, the centre bud generally with five or six smaller ones round it; flowers, of a

yellowish tint, appear in May and June; cones, 2 to 3 inches long, and 1 to $1\frac{1}{4}$ inch broad, more equal in thickness and smoother than those of the white-wooded variety, which are more elongated and tapering; seeds, black, and garnished with a reddish wing, and ripen the second year; branches, horizontal, with a tendency to bend downwards; bark, comparatively smooth and light in colour, not so rugged as in the degenerate variety. As an ornamental tree it is generally found single or in small groups, height 30 to 60 feet, with wide-spreading horizontal branches reaching almost to the ground. When seen thus there are few trees having such a picturesque appearance, and so distinctive a character. As a forest-tree it averages 60 to 80 feet in height, with a clean trunk, occasionally inclining to be flat-sided, but with little taper, and the branches at the top small, and disposed in regular whorls. Of course any or all of these characteristics may vary slightly according to soil, altitude, exposure, and extent of plantation, but we consider them sufficient to guide the practical forester in the selection of the true variety of our native Pine.

The Soils and Situations where found Growing, and best suited for its Proper Development.

The *Pinus sylvestris* is now found, either wild or cultivated, throughout the greater part of Europe. It is the only Pine indigenous to Britain, and its chief native habitat is the Highlands of Scotland—hence the name "Scotch Fir." But though it is termed the Scotch Fir, it is by no means peculiar to Scotland. It has a very wide geographical range throughout the northern part of the eastern hemisphere, where it forms vast natural forests, extending from the middle of Europe to the 70th degree of north latitude, but ceasing in Asia at 63°. It is only in temperate regions that it luxuriates, and there the most extensive and valuable forests are found. In Scotland these give a character to the landscape, so that the noble Pine has been termed "the king of Scottish woods." While granting that title to be due as regards the Scottish woods, if we cross the border we must not presume to give our favourite Pine any such designation, as all authorities allow the Oak to be termed "the monarch of the woods;" but, as there is nothing essential in a name, we are content when conversing with our southern neighbours to call it "our native Pine." In the lowlands of Scotland few plantations or forests, composed entirely of Scotch Pine, are to be seen, it being chiefly used in that part of the country as a nurse for other trees, or for making up mixed plantations. It seems evident that it must have been used in this way at an early period, and, at present, most of the finest specimens of the Scotch Pine in the Lowlands have been grown amongst hard-wood trees, principally Oaks. These Pine trees, though considered handsome in their own locality, are not to be compared with the noble specimens found in the north of Scotland. It is a matter of regret that some of the noblest of these are disappearing before the woodman's axe. We agree with the general rule that trees should, like any other crop, be cleared off the ground when they arrive at maturity, so that the ground may again be turned to profitable account; but we think that regret will be general with the members of the Scottish Arboricultural Society that so many fine old specimen trees of our native Pine are ruthlessly cut down. Every available means ought to be resorted to for their protection and preservation; in fact the words, "Woodman spare that tree," should be displayed around them, so that the casual observer might know that the tree before him was a "king of the Scottish woods." The proprietor of Invercauld, with praiseworthy zeal, has had a number of the best Scotch Pines on his estate photographed, and through the kindness of Mr. Brown, his late factor, these have been presented to the Scottish Arboricultural Society, so that their shadows may be preserved when their substance is gone. The most famous districts in the north of Scotland for the growth of Scotch Pine are the valleys of the rivers Spey and Dee, with their tributaries, the chief places being Rothiemurchus, Duthill, Abernethy, and Glenmore on the Spey, and Invercauld, Braemar, and Glentanner on the Dee. These famous Scotch Pine producing districts, though far apart, have a great deal in common as regards the natural formation of the ground, hill and dale alternating with wide-stretching valleys, sheltered by neighbouring hills, soil light and gravelly, inclining to clay in the valleys, and the sub-soil granitic, geological formation chiefly grey and red granite. The comparison also holds good from a financial point of view, for in these districts wood has been the chief source of revenue to the proprietors, and affords a staple industry to the people. Again, in comparing the recorded sizes of the famous trees, each district vies with its neighbour in producing large specimens and good timber. At present Ballochbuie at Invercauld is considered the best and most valuable Pine forest in Scotland. Most of the others mentioned were at the zenith of their maturity about the beginning of this century. We have enumerated several of the most famous Scotch Pine producing districts, but there are other localities, as Monymusk on the Don, and the Scotch Fir planta-

tions near Fochabers, belonging to the Duke of Richmond, where timber scarcely inferior in quality has been produced. During this century the quantity of Pine wood that has been cut and manufactured in the north of Scotland is very great, so that it has been a chief staple of commerce. Notwithstanding all that has been felled, there is at present a greater extent of land under Scotch Pine than at any previous recorded period. Of course the greater the area, the more diversified are the soils and situations, and it is not to be expected that all the plantations will produce large trees. Judging from the soils and formation prevalent in the districts where the best specimens occur, it is evident that a light gravelly or sandy loam, with a granitic formation and north exposure, at an altitude of 500 to 800 feet, is the most favourable situation for the proper development of the Scotch Pine. Although this is undoubtedly the best, still the Scotch Pine is suited to a great variety of soils and situations; in fact it will grow, and that profitably, on any soil (except chalk) from a sand to a clay or Moss, provided there is no stagnant water, and the sub-soil is rubble or rock. In some natural forests this Pine grows on poor sandy soils, but it does not follow that, because found on these poor soils, they are adapted for its proper growth. This is only the result of seeds blown about by the wind, germinating more freely in sandy than in retentive soils; and, when once established, the Scotch Pine grows more freely in these light sandy soils than almost any other tree.

Except as a nurse for more valuable trees, the Scotch Pine should never be planted on wet tilly soils, for whenever the roots have exhausted the upper portions of these soils, and penetrate to the cold sub-soils, the vital energy of the plant is checked, and, as a natural consequence, it languishes and dies. Light gravelly soils, with a moorband pan near the surface, are inimical to its growth. On ground of this description, left in its natural state, the Scotch Pine seldom grows above the shrub size; but as the surface soil is suitable for the growth of Scotch Pine, the moorband pan can generally be remedied, or got rid of altogether, by thorough drainage. Good specimen trees are found in most of the eastern and southern counties growing on strong clay soils and well-drained Moss. We know one instance where, for trees grown on a strong clay soil, a wood merchant offered £1,000 for 1,000 unpicked Scotch Fir trees. Trees grown on this sort of soil have been frequently sold at from 10s. to 15s. each. Of course the access to the plantation was easy. These may seem very high figures for Scotch Fir trees; but they are facts, and we think the policy of planting slow-growing hard-woods on soil of this description is questionable, especially as the market for slow-growing hard-wood, unless of a large size, is steadily decreasing. We are not prepared to affirm that the timber of Scotch Pine, grown on Moss soils, is as good and durable as the timber grown on more suitable soils; but, except for carpenter work, it is suitable for all the purposes to which the timber of the Scotch Pine is applied. In contracting for railway sleepers of Scotch Fir, it is generally stipulated that they are to be of the best description; but under close inspection, we have never known objections raised to timber grown on Moss or soft ground. Except for timber used in carpentry, any objection that might be raised as to the quality of Pine timber would be of little importance, as with the chemical appliances now used for the preservation of wood, the quantity of timber produced in a given time is the first consideration, and quality only the second.

No forest-tree with which we are acquainted adapts itself more easily to change of circumstances and variety of soils and situations; and the Scotch Pine may be considered the safest tree to plant in Scotland, especially on the waste and barren ground so prevalent in some parts. Some political agitators state that about the one half of the ground in Scotland is lying waste, and ought to be improved, so as to produce food for the people. Another class, who are arboriculturally inclined, maintain that all the barren lands ought to be planted—Scotch Pine being the tree most recommended to produce the wonderful transformation. On examination, both theories prove delusive, so far as the growing of either cereals or Scotch Pine on all the waste and barren lands of Scotland is concerned. After a careful and extensive examination of waste and barren land, we confidently assert, that on a large portion of these barren lands it is impossible to grow even Scotch Fir, owing to exposure and want of soil. We have observed that the Scotch Pine is most accommodating to soil and situation; but there are peculiarities as to altitude not easily accounted for. In "The Forester," p. 237, it is stated that "the Scotch Pine is found growing at an altitude of upwards of 2,000 feet." In the Rothiemurchus district, useful and profitable timber is grown at 1,500 feet; and in the Dee district, there are numerous localities where good wood is grown at from 1,000 to 1,200 feet. This fact is encouraging; but on some hillsides it is impossible to get it to grow above 800 or 1,000 feet. Our observations lead us to conclude that shelter and exposure must be considered in deciding

the altitude at which the Scotch Fir can be grown profitably. On a sloping hillside, fully exposed to the prevailing wind of the district, we have known Scotch Fir to fail, as a crop, at an altitude of 700 feet; while on the same hillside, but in a sheltered position, it grew freely at 1,000 feet. Again, on a sloping hillside, ranging from 500 to 750 feet, the trees, though healthy and good, are short, and only average 8 or 9 feet; while on the top of the hill, there is a good portion of flat or slightly hollowed surface, and the trees there of the same age average 14 to 15 feet. On another hill Scotch Firs are growing freely on the flat summit upwards of 1,000 feet; and on the exposed slope they are little better than shrubs. Some may think this overstated, and name instances where Scotch Pine grows freely on hillsides; but these hillsides are invariably sheltered by other, though perhaps distant, hills, and therefore the prevailing wind has little effect on them. These remarks are not made to discourage proprietors from planting exposed hillsides; but we would humbly say, be not too sanguine of success, nor expect the profit that is realised from trees grown on suitable soils and sheltered situations; for although the Scotch Pine will, for a time, grow on almost any soil and in any situation, like all other trees, it prefers a good suitable soil.

Cultivation and Value at Different Periods of Growth.

We have stated that the area of land under Scotch Fir is greater at present than at any formerly recorded period; but, when we examine the kind of cultivation it receives, we find that most of the plantations receive no attention from the time they are planted until they are of a size suitable for the many purposes to which the thinnings of Scotch Fir plantations are applied. Most plants are improved by cultivation, some so much so, that their character and constitution are completely changed. The Scotch Fir, perhaps, has improved less by cultivation than any other forest-tree; and it has been said to be one of those plants that receive no apparent benefit from cultivation. To a certain extent we indorse the statement; but the question arises,—Has the cultivation of the Scotch Fir been judicious or not? In some instances the cultivation has been all that could be desired, but generally the answer must be in the negative. To particularise instances of judicious cultivation would be invidious and personal, and at best could only benefit such as have opportunity of personal inspection. A standard of perfection to be aimed at will be more useful. We consider three operations to need special attention for the judicious cultivation of the Scotch Fir, viz., first, the selection of seed; second, the treatment in the seed-beds and nursery-lines; and, third, the thinning, &c., during the first twenty-five years of growth. Of these, the selection of seeds is the most important; but it is seldom performed in a way to procure the seeds of the best varieties. It depends chiefly upon seed collectors, whose only object is to procure the largest quantity of cones at the least possible expense. At no distant period, the nurserymen sent their own seed collectors to the principal districts; but gradually (as the result of keen competition and the demand for cheap plants) seed collecting became a distinct branch of business. Now nurserymen have not the same facility of ascertaining the particular district from which their seed are procured. Of course the district is mentioned, but the main consideration is the parentage of vital seeds. There are still some nurserymen who continue to collect seed and guarantee the forest from which it is procured; and it is creditable to know that these are much patronised, although their seeds and plants are charged at a higher rate than those procured from other firms. The method adopted by the professional seed collector is to arrange with district collectors to supply a given quantity of cones at a certain rate. These district collectors, in their turn, arrange with local agents; and generally, if the quantity of cones is procured, no questions are asked as to what plantation or kind of trees supplied them. It is not uncommon to see people of all ages, and of both sexes, scampering through Scotch Fir plantations, gathering cones, wherever they can be easily procured. Cones are often most abundant on deformed and worthless trees, the tendency to produce seed being a symptom of maturity, or, according to Darwin, an indication of disease. It, therefore, follows that a large portion of Scotch Fir seed is at present gathered ostensibly from the best districts, but really from the worst trees in these districts. The result is the natural consequence of the system, and will not be remedied till all seeds are gathered under skilled supervision. We have already dwelt upon the best varieties of the Scotch Fir, and how they may be known by their cones; and, as our standard for its cultivation, we recommend that the professional seed collector should personally, or by deputy, select not only the districts, but the forests or plantations; and to ensure the seeds being procured from the best trees, a responsible person should superintend the operation.

The treatment of the seed beds and nursery lines is generally well understood by practical arboriculturists. Instances occur where the cultivation is not skilful; but this operation being open to inspec-

tion at all stages, the observer may detect instances of bad cultivation, and avoid them accordingly. In general the cultivation in the nursery is fair. The principal errors are high manuring of the ground, overcrowding of the plants, and too much shelter. Highly manured ground is injurious to the development of the Scotch Fir at all stages, although its bad effects are not so observable at this stage. But when planted out, especially in exposed ground, the effects of high manuring are soon noticed. However, if the soil is good, and the plants get a fair start, the effects readily pass away. The case is different with Scotch Fir plants that have been overcrowded either in seed beds or nursery lines. No amount of care in after treatment can remedy injuries received at this stage. In fact, experience teaches us that under no circumstances will overcrowded plants attain the same robust habit or become as profitable a crop as plants that have been allowed ample space for the development during the early stages of growth. The reasons are obvious, and not peculiar to the Scotch Fir. They are—First, A want of roots, fibres, and spongioles, which are essential to the vitality of plants. Second, A deficiency of leaves, necessary for the transpiration or exhalation of the superfluous fluids, and for absorbing from the atmosphere the substances that are subservient to growth. Third, A contraction of the diameter of the stem, and consequent check on the formative cells or cambium, which forms liber, alburnum, and wood. Fourth, A slender habit and bad constitution, caused by a deficiency in these vital parts. It occasionally happens that the seed-beds are overcrowded unintentionally, and under the best management; but when such is the case, they should be thinned at once, and planted in lines or bedded as one-year seedlings. As to overcrowding in the lines, it should never occur. Too much shelter is often as injurious to plants as overcrowding; in fact, the two generally go together. Shelter does not injure a plant so long as it is in the nursery, but a plant grown in an over-sheltered place cannot be removed with safety to the open ground. Other causes of mischief occasionally occur in the nursery, as Fungus, beetle, mildew, &c.; but these are generally checked as soon as observed, although sometimes after great loss and disappointment to the cultivator. Our standard at this stage should be good habit, tapering form, and sufficient fibrous roots, leaves, and branches. A plant of this description will grow and succeed in any situation.

The thinning, &c., of Scotch Firs during the earlier periods of growth is the next point in their cultivation, and one which is seldom sufficiently attended to. Good seed may be procured, good plants produced, and planted in suitable soils and situations; but if thinning is neglected, they suffer more from overcrowding at this stage than in the nurseries, and there is less excuse for it. Generally Scotch Fir plantations are more neglected at this stage than any other. This may sometimes be attributed to the extent of these plantations, and the consequent expense of thinning, without any present adequate return. None, except those who have experienced it, know how difficult it is to get proprietors, who take no interest in their plantations, to expend money on thinning. There are, sometimes, difficulties in the way, even where the thinnings would pay the expenses. Another great drawback to the early thinning of Scotch Fir plantations is the opinion, sometimes freely expressed by men who ought to know better, "that to produce clean grown timber, Scotch Fir cannot be grown too crowded together." We have frequently seen plantations under the charge of individuals who hold this opinion, and we confidently assert, that instead of plantations treated in this manner producing clean timber trees, they scarcely ever produce a crop of profitable spars. A favourite argument against thinning Scotch Fir plantations is to point to some patches or groups of really good trees that may be growing in such a manner as clearly proves that they have not been thinned. We at once grant that such instances do occur; but they are the exception and not the rule, and only go to prove the Darwinian theory of the struggle for existence. Personally we have examined many Scotch Fir plantations, and have never met with an instance of a good crop of wood, even in prospect, where the trees had been planted at the ordinary distance apart, and their thinning neglected until they were a suitable size for propwood. If such an instance is known, we feel assured that it arises from exceptional causes. The practical operation of thinning has been minutely described in the "Transactions" of the Scottish Arboricultural Society; to enlarge on it would only be to repeat in substance what others have so well written; and those who neglect to thin their plantations cannot plead the want of sufficient information on the subject. Making due allowance for soil, situation, and exposure, we would say that Scotch Fir trees should have ample space for development of roots and branches during the earlier stages of growth. To ensure this, thinning is generally needful at eight to twelve years after the plantation has been formed. Occasionally we have thinned at an earlier age, where the trees had been planted at three feet apart on good soil. The first thinnings are not

worth removing, except they are required for brushwood, screen fences, &c. They are generally given at a nominal price to ensure their removal. The second and third thinnings are generally suitable for light propwood, and when conveyed to market are worth from 3s. to 4s. 6d. per hundred lineal feet. When the trees are from twenty to thirty years old, a thinning of full-sized propwood may be taken, which, when conveyed to market, are worth from 5s. 6d. to 7s. per hundred lineal feet. At this stage the standard crop of trees will be at an average distance of from 9 to 12 feet apart; and if the management has been judicious, the plantation may be allowed to rest, *i.e.*, the trees to get drawn, in the assurance that a full crop of good timber trees are in prospect.

The foregoing remarks express our *beau idéal* of the judicious cultivation of Scotch Fir plantations. Owing to the many changes that take place between the formation of a plantation and its maturity, it is difficult, often impossible, to procure exact information as to the early treatment of the best of our Scotch Pine plantations, consequently, many of the conclusions must necessarily rest on circumstantial evidence. However, we know several instances where we have been assured, by resident parties, that the treatment has been similar to the above recommendations.

The Diseases to which, as a Forest Tree, it is most liable.

One of the most fruitful sources of disease—stunted growth and premature decay—in Scotch Pine plantations is the total neglect of thinning when the trees are young, and then too severe thinning after they have come to be of useful size. We have already adverted to the importance of thinning, and the loss sustained by neglecting it. We would only add, in treating of diseases, that the neglect of thinning predisposes Scotch Pine trees to almost every disease to which they are liable. As an illustration, we would only mention that the small white protuberances (than which there are no surer signs of decay) in the bark of Scotch Fir seldom occur except on trees that have had their roots shaken and partly broken, by being too much exposed to the wind, and are always most common in neglected plantations the season after a severe gale of wind. The common causes of disease in Scotch Pine, and which tend to hasten premature decay, are—First, ground-rot caused by the tap-roots failing to obtain sufficient nourishment from the sub-soil, generally most prevalent on light gravelly soils, with a hard impervious sub-soil; deep drainage is the best preventive.—Second, roy or trunk-rot, most prevalent in old plantations, and is a sure sign that the trees have passed maturity, and, as a crop, ought to be realised.—Third, ulcers or resinous boils, generally caused by the bark being damaged, sometimes by accident, but more commonly by insect eggs being deposited in the bark, and as soon as the larvæ begin to develop, they eat into the sapwood, and cause the natural juices to run out; trees seriously affected with this often break over at the disease part.—Fourth, want of drainage, and stagnant water; the remedy for this is not far to seek, but frequently the crop is sacrificed before the remedy is adopted.—Fifth, Fungus; this is a disease affecting the roots, and only met with in highly-manured ground, most common in the nursery. On highly-manured and cultivated ground (naturally poor) we have known fifty per cent. of the Scotch Pine trees die from Fungus and white bug before they were eight years planted. Some of the natural enemies of the Scotch Pine, when young, are ground game, field-mice, white bug, Pine-leaf caterpillars, black game, and brown beetle. This latter and its varieties prey on the Scotch Pine at all ages, and, if not checked, threaten to damage some plantations very materially. After a crop of Scotch Fir is cut, the ground is sometimes so much infested with them that it is found impossible to get a second crop to grow until the ground has been cleaned. The beetle generally injures young plants by cutting the bark near the surface, but in older trees it eats into the pith of the top or leading shoot, and the points of the lateral branches. We consider that the best preventive is to keep the surface as clear of rough herbage and superfluous branches as possible, as we have never seen a plantation that was regularly grazed much affected with beetle. Squirrels are also very injurious; the best remedy is to kill them, but not by shooting, as the trees are sometimes more injured by the cure than the disease. These are some of the diseases and their causes that are generally known; but unless where they are observed and checked at once, little is practised or known as regards their remedies, if indeed remedy is possible with some of them. We sometimes think that the "stamping out system," so strongly urged by the Aberdeenshire farmers during the cattle plague, must have been borrowed from the foresters, for it is seldom that any curative means are tried with diseased trees. They are generally cut down (*i.e.*, "stamped out"), and turned to account. However, we trust that the improvements begun in the art of forestry will continue, and tend to maintain the prestige of our native Pine as "the king of Scottish woods."—*Scottish Arboricultural Society's Proceedings.*

BURNHAM BEECHES.

THE picturesque and curiously interesting old wood, called Burnham Beeches, forms part of the manor of East Burnham, and adjoins a wild common distant about four miles from the railway station at Slough. Up to the time when railways were introduced, there was not a nook of the country, far or near, more secluded or less known than Burnham Beeches was. Londoners appear to have been entirely ignorant of this picturesque tract, although the poet Gray—whose favourite walks were in its shadowy depths—speaks of it in his letters. In Moore's "Life of Sheridan" will be found a series of letters, written from East Burnham Cottage, by Sheridan. At that time Burnham Beeches was one of the wildest and most romantic of our ancient forest remains; the axe of the woodman had left it untouched, and its owners, generation

may be reached by several roads, each very beautiful in its seclusion. We ascend a hill, and find a sort of table-land, forming a rude common with a few scattered houses. Gradually the common grows less open; we see large masses of wood in clumps, and now and then a gigantic tree close by the road. The trunks of these scattered trees are of amazing size. They are for the most part pollards, but, not having been lopped for many years, they have thrown out mighty arms, noble as well as beautiful in their grotesque proportions. As we advance, the wood thickens, and, as the road leads us into a deep dell, we are at length completely embosomed in a leafy wilderness. This dell is a most romantic spot; it extends for some quarter of a mile between overhanging banks covered with the graceful fronds of the Ash and the Birch, while the contorted Beeches show their fantastic roots and unwieldy

One of the Burnham Beeches.

after generation, had scrupulously preserved its primitive aspect. The oldest inhabitant alive, in 1856, one William Buckland, said for fifty years he had never known one instance of a tree standing on the waste or forest being cut down. After the year 1840, when the railroad came into use, the neighbourhood became better known and its sylvan solitude gradually became the favourite resort of summer pleasure-parties from the surrounding districts. The late Charles Knight, describing the place at this time, says—"We know nothing of forest scenery equal to Burnham Beeches. There are no spots approachable to it in wild grandeur to be found in Windsor Forest." Sherwood, we have been told, has trees as ancient, but few so entirely untouched in modern times. When at the village of Burnham, which is about a mile and half from the railway-station at Maidenhead, the Beeches

trunks upon the edges of the glen in singular contrast. If we walk up this valley, we may emerge into the plain of Beeches, from which the place derives its name. It is not easy to make scenes such as these interesting in description. The great charm of this spot may be easily conceived, when it is known that its characteristic is an entire absence of human care. The property has been carefully preserved in its ancient state, and the axe of the woodman for many a day has not been heard within its precincts. The sheep wander through the tender Grass as if they were the rightful lords of the domain. We asked a solitary old man, who was sitting on a stump, whether there was any account as to who planted this ancient wood. "Planted!" he replied, "it was never planted. Those trees are as old as the world!" However sceptical we might be as to the poor man's chronology, we were sure that

history or tradition could tell little about their planting. The ancient tradition of the neighbourhood tells how the Beeches were pollarded by the Parliamentary army under Cromwell which encamped there during the great civil war, but some have denied that they ever were pollarded, although their appearance is certainly such as that process might have produced. At any rate the tradition helps us to estimate the age of the trees. Of course these quaint, grotesque, and picturesque old giants in their present deformed and maltreated condition have not the stately grandeur and symmetrical beauty of the Beech in its natural state. Their monstrous sizes—most of them must have a girth of from 14 to 18 feet, and some of them measure over 20 feet—their fantastic profiles, and wild weird-looking attitudes, giving them in the dim twilight of the wood an aspect calculated to awaken the wildest superstitions in the minds of forlorn and wandering travellers, have now long been the delight of artists, whose paintings and drawings have conferred upon them a species of immortality; but the gracefully arching branches, the tall straight trunk, with its smooth grey bark, and its seeming cluster of banded pillars, with other characteristics which have won for the Beech its title to regard as the grandest of forest trees, are altogether absent in these gigantic specimens.

Lichens on Trees.—I should be much obliged if any of your correspondents would inform me what conditions of atmosphere, soil, and temperature are most conducive to the formation and growth of Lichens on trees, stumps, &c. I had imagined that dampness of soil and atmosphere were the chief promoters of Lichen, but this theory seems rather contradictory to a fact I have lately observed, viz., a very inordinate growth of Lichen where the soil is chiefly sand and gravel, with a light peat on the surface. If damp causes it, wherein does this cause differ from the cause of the development of Mosses? and has vicinity to sea air anything to do with the formation? Is there any book on Lichens?—C. J. WRIGHT.

Gum Anime.—In an article on Amber in your number of the 13th Dec., I find it stated that gum animé is the produce of a North American tree, and is a modern secretion forming at the present day. As this was quite opposed to the account I had always heard of the gum animé of commerce, I have searched for some information on the subject, I find a letter from Dr. Kirk to the Linnæan Society, dated Zanzibar, March 20, 1868, in which he states that along the creek of Dan Salam on that coast he finds among many other shrubs the *Trachylobium Mossambicense* which produces one variety of Copal, and he proceeds to give his reasons for believing that in this tree we have the source of the older Zanzibar Copal, the semi-fossil or bitumenised resin known in the English market as animé, and which is the most valuable of all resins for the manufacture of varnish, exceeding anything produced on the west coast for hardness, elasticity, and polish. There are three distinct kinds of Copal in Zanzibar, the first the tree Copal; second, Copal dug from the soil in places where the Copal tree now exists; third, the animé, also dug from the soil, but harder, less soluble, and more than twice the value of the other kinds. The *Trachylobium Mossambicense* is found only along the creeks and becomes very rare at a little distance inland, and quite unknown long before the change in geologic structure offers an explanation of its absence. It requires the near presence of the sea and dies when far removed from its influence. The animé is, undoubtedly, the produce of forests now extinct, for there are no trees growing along the ancient sea beach which produces it, and which here fringes the Continent to a depth of 20 to 40 miles in general. It is dug up by the natives after the rains have softened the soil, and the supply appears practically unlimited.—W. H. MOBERLEY, 23, Great Winchester Street, E.C.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Chimonanthus fragrans.—This is now flowering very freely on warm sunny walls, and is one of the most useful of winter-blooming outdoor shrubs. The large-flowering variety is much finer in every respect than the common form, and intending planters should procure it if possible. We may again call the attention of propagators to the fact that this plant has never been struck from cuttings, a circumstance which induced the late Dr. Lindley to offer a guinea to any of the young gardeners at Chiswick who might bring him a rooted cutting of it.

Golden-tinted Spruce Fir.—This richly-coloured form of the common Spruce Fir bids fair, when abundant, to become a popular tree for planting in bleak and desolate localities, as the rich hues of the foliage are always best in the winter months. It is perfectly hardy, and is as robust in growth as the green variety. As it is not amenable to increase by the ordinary mode of cuttings, the stock is worked by means of layers, some large plants having been laid in the Fulham Nursery for that purpose. Under the name of *Abies excelsa aurea*, it has already received a first-class certificate at South Kensington.—D.

THE KITCHEN GARDEN.

CULTIVATION OF CARROTS.

THESE roots are in request every day in the year in all large kitchens, and are also a most valuable root for cattle-feeding and hog-fattening, as no other root that we cultivate produces finer flavoured beef and bacon than the Carrot does, which I have practically proved. I have grown above thirty tons to the acre of the Long Surrey Red and the Green Top, and considerably more of the White Belgian sort; but, to grow such heavy and clean crops, the soil should be a good sandy open loam, deeply cultivated, thoroughly pulverised, and kept rigidly clean. Sow moderately thin, and timely, on land that was manured the previous year. Never sow Carrots on newly-manured land, as they are sure to become forked and branch-rooted, seeking after lumps of manure distributed amongst the soil; and, besides, they are very likely to get attacked with the maggot and canker, are bad keepers, rough and ill-looking, and consequently much reduced in their value. In order to get a heavy clean crop, cultivate the soil deeply in winter, and expose to the influence of the atmosphere the greatest possible surface of rough-lying ridges. Rout it about only in frosty or dry March weather; and, when all is in good order and in readiness for the seed, which should be sown for the main winter-storing crop by the last week in March, or the first or second week in April, according to season and conditions, have ready some hot air-slaked fresh lime, of which cast a moderate coat over the land, which should be harrowed well to incorporate the lime with the soil, and also drill in the seed with air-slaked hot lime, and the return will be a heavy crop of clean handsome Carrots, fit for any table or other use. To have young Carrots fit for table every day in the year, choose the Early Horn and French Early Forcing, and sow them, about the 1st of January, on slight hot-beds close to the glass in frames or pits, and also a succession in February for supplying the table from March till May. Sow also on a warm border out of doors in February, to be protected by some kind of covering; and, to keep up a good succession, sow every month out of doors till September. The largest sowing should be made in July and August for a good supply throughout the autumn and winter; but they will require some temporary protection when winter frost sets in. Make a small sowing on a slight hot-bed, in a pit or under frame-lights, the first week in October, and nice young Carrots will be the return for every day throughout the winter and early spring. In storing large bulks of Carrots for winter use, never place them too thickly together, as the roots are apt to heat and sweat very much. Place them between hurdles, not more than 3 feet apart, and finish the top in ridge shape, protecting the sides and top with bavons, or rough faggots, or Furze tied in bundles, and thatch the top with straight straw. If severe frost sets in in winter, protect the sides with additional Furze, litter, Fern, or Heath.

JAMES BARNES.

Exmouth.

LEEKs.

To GROW these large, crisp, and of mild flavour, we require good rich land, well trenched, pulverised, and manured. Sow in the middle of March and again in April. In order to grow them large, and blanch a good length of them, throw out a shallow trench 18 inches wide, and plant them in two rows for the convenience of earthing up, in order to blanch them, and also for a slight protection when severe frost sets in. Fifty years ago they were but little grown in this country, and were only distinguished by the name of "Leek." Of late years, although many varieties have been brought out as new, or under new names, such as Henry's Prize, Large Rouen, Ayton Castle, Giant, &c., the old London-Flag, when well cultivated, would hardly be distinguished from the Giant, or any other kind with a new name.

J. B.

Early Peas.—On the 17th of November I sowed in a south border here, William the First, Sangster's No. 1, Sangster's Improved, and Racehorse. The three latter are appearing here and there, but the former, William the First, is fully up in the rows, which I have covered with coal-ashes. This is a fine hardy variety, of a deep green colour, and in flavour is all that can be desired. I should certainly recommend it to all my gardening friends.—R. GILBERT, Burghley

THE FRUIT GARDEN.

BIRDS VERSUS GRAPES.

IN THE GARDEN the other day I noticed an article under the above heading. I fully agree with your correspondent "B.," as to the paper collar being a good protection to the fruit, as the top or "shoulders" of the bunches are sure to be attacked first, and the Robin is generally the bird that performs that operation. Will you kindly allow me to state what I have found to be a more effectual safeguard? I use neither bags nor paper; but to every alternate light, front or top, I have a perforated zinc light, made to fix inside the glass ones. The door of the house is made light, and the panels, instead of glass, have the perforated zinc as for the lights. When the fruit is gathered, they—the zinc lights—can be removed into store, and will last as long as the fruit-house itself. They save all trouble of sugar-and-beer bottles, muslin bags, &c., and effectually protect the fruit, so that I can leave the houses with air on day and night, at ripening time (in fine weather), without fear of mice, rats, birds, wasps, or bluebottle flies. I took the idea from the meat-safe principle, and my employer with whom I was living some eleven years ago, kindly gave me permission to have lights made at once. May I add that for fruit structures, especially Vine houses, I prefer those glazed to the rafters, to those with running lights; as one can have air on at front and back, no matter if it rains in torrents; a little fire-heat and you have no damp, and the perforated zinc, nicely breaks or filters the air. Whence comes the mildew? Why, in nine cases out of ten, from a damp stagnant atmosphere. A gentleman, visiting here the other day, told me he had had a large crop of Grapes, but had the greater part of them quite spoiled and eaten by wasps and large flies, although they had the wires between the Grapes literally covered with bottles of beer and sugar, and some bunches enveloped in bags, but the wasps made a way through to the Grapes. I do not write this thinking my plan may not be used by others, but I say to those who have not tried it, whether to the individual in a small way, or to those who have a large extent of glass, that they will find it beneficial and, in the end, economical.

JAMES BATTERS.

Chilworth Manor, Romsey, Hampshire.

PECULIARITIES IN GRAPE CULTURE.

THERE are several varieties of Grapes which are acknowledged by all to have their individual points and qualities of excellence, but which are very often subject to defects and faults; and we think that a few remarks relative to our experience with these may perhaps prove useful to some of our readers. The subject cannot be regarded as unimportant, seeing how very popular a fruit the Grape has become, and how many, comparatively inexperienced, are now attempting its cultivation. Certainly there has been a great amount of remark and information brought out in the gardening press from time to time on the peculiarities of culture most likely to ensure success in the case of several desirable Grapes; but that information lies in a very scattered form, and we propose to give in a brief, but, at the same time inclusive, shape, our experience with some of these varieties, and begin with one of the finest of late black Grapes.

Gros Guillaume.—In some instances, this showy and excellent Grape is rather a shy fruiter, especially when pruned on the spur system; and sometimes it does not colour well, and the berries swell unequally. We have found it develop these peculiarities on its own roots. To obviate such defects, some have recommended that it should be grown in poor sandy borders. We have found that grafting it on the Muscat of Alexandria causes it to fruit as freely as a Black Hamburgh when spur-pruned; every berry swells equally, and invariably it has coloured to the deepest purple. We consider the bunches more compact on the Muscat than on its own roots; the berries always larger and perfectly regular. Grafted on Black Hamburgh, it did splendidly for a couple of years; but each year degenerated in every respect till we cut it out. When calling at Chiswick Gardens last July, we were informed that there, on Hamburgh roots, it manifested the very same tendency. We consider that on Muscat roots, in Muscat heat, Gros Guillaume is one of our grandest Grapes. In 1872 we cut six bunches from a graft put on a Muscat in 1870. The largest of the six weighed 9 lb., and the least 5½ lb. The style of bunch was far superior to those on a

Vine on its own roots in the same house, and the quality was better.

Muscat Hamburgh (Black Muscat).—We have never met with this variety well set on its own roots but at one place—viz, Eccles, in Dumfries-shire, grown in a red-sandstone loam. Here every berry stones like a Hamburgh, and there has been produced a bunch 7 lb. weight; but the defect is that they never colour beyond a brownish-black. Grafted on the Black Hamburgh it sets perfectly, and colours as well as can be desired if not grown in too high a temperature. Like some other black Grapes, I have observed that in Muscat heat it does not colour well. The warm end of the Hamburgh-house is the place for it. Few Grapes can surpass this one either for appearance, flavour, or long-keeping qualities. We have had it 5 lb. weight on Black Hamburgh roots; but Mr. Fowler, of Castle Kennedy, has shown it heavier—and its size is its least valuable quality.

Black Lady Downes.—This, as is well known now, is a strong free-fruitering Vine, and chiefly esteemed on account of its unsurpassed long-keeping quality, and is largely grown for hanging till spring. But like most other Grapes, it is not perfect in its behaviour. In hot summers it gets sadly decimated by the berries getting scalded; and some of our scientific (?) but impractical men have attributed the affection to some defect in the root action; it is clever, of course, to know this, when it cannot be demonstrated nor seen. The cause of the scalding is more heat than this Grape can do with just at the stoning point, and the remedy is simply to give abundance of air till the stoning period is over. We have during the last few years had scalded bunches sent to us to inspect, and have heard from the senders afterwards that increase of ventilation had completely prevented it.

Alicante.—This Grape is among the most easily cultivated, and generally finishes well. We have noticed that when it chanced to be planted in the Muscat-house it did not colour well in the high temperature. The same applies to another not very desirable but free-fruitering Grape, Burekhardt's Prince, which never colours well in a high temperature.

Muscat of Alexandria.—There are varieties of this Grape which set and generally ripen and colour better than others. In many instances Muscats do not attain that high colour which indicates the best quality, and ensures their hanging well. It is about the best of all keepers. We have known it perfectly ripe in August and hang till the end of March. Some attribute the very high colour and quality which this grand Grape sometimes attains to soil and climate; others to bottom-heat. It is generally well coloured in the east of Scotland, where the climate is dry and the soil rather light. But we have seen it quite as finely finished in the gloomy south-west of Scotland in heavy soil. We have never failed in colouring Muscats well; and we attribute it chiefly to keeping the soil dry, or, at least, preventing its getting too much wet, and more especially to keeping the foliage rather thin over the bunches, and even tying it aside to let light at the bunches after colouring begins. Badly-ripened green Muscats are about the most worthless of Grapes, yet no one thinks of condemning them *in toto*. It is well worth while continuing to grow them, and to try every means of bringing them to the highest pitch of culture.

Frontignans, grizzly and white.—A few of these should be grown wherever there are a few Vineries. They are fruitful, early, and of exquisite flavour, and do pretty well on their own roots, but much better when grafted either on the Muscat of Alexandria or Black Hamburgh. They give finer bunches and larger berries than on their own roots. They are best in a Muscat temperature, but do very well at the warm end of a Black Hamburgh-house.

Golden Champion.—The great fault found with this Grape is that it spots. It is so noble-looking and luscious a fruit that it is well worth the time and patience, observation and experiment, which, as in the case of other Grapes, will establish for it a rule of culture that will grow it free from spot. It is a tender-skinned Grape; and, if grown in a Muscat-house—where it ripens before the Muscat—and subject to a high temperature, with moisture, with not enough of ventilation, it of course spots. The place for it is the Black Hamburgh-house—grafted on Muscat roots—where it will get abundance of dry air as soon as, or even before, it begins to change colour. Managed in this way, it ripens without spotting. It sometimes cracks in wet weather. The first indication of cracking should be the signal for cutting the shoot half through below the bunch, and, if possible, throwing the rain off the roots. It is well worth while to take these simple measures in the case of so noble a Grape as this is. We have never known it figure in the dessert yet, but it was praised as the grandest of Grapes.

Duke of Buccleuch.—Perhaps this may supersede the last-named, and perhaps, also, it is too early in its history to speak of its peculiarities. We have, however, had opportunities of watching some of the finest examples of it that have yet been grown, and the

conclusion we have come to in reference to it is that, though a grand Grape, as it proves to be on its own roots, we think it better still grafted on the Muscat of Alexandria. The finest we have seen of it were on the Muscat stock in a Muscat-house. But it ripens so long before the Muscats, that the heat necessary for the Muscats is detrimental to the Duke; consequently, if grown in the Muscat division, it should be at the coldest end. Anywhere in the Ham-burgh-house is the place for it, where it hangs for months after it is quite ripe.—*Gardener.*

THE AMATEUR'S GARDEN.*

PALMS FOR THE DINNER-TABLE.

Few plants are so well adapted for the decoration of the dinner-table as Palms, and nearly every species in cultivation is valuable for this purpose when in a young state. Some of the slow-growing species may be used for several years in succession, while the other and quicker-growing kinds are easily grown on for this purpose from seeds. These elegant plants are not only as graceful as the most delicate Ferns, but far better fitted to withstand the aridity of apartments heated by either coal-fires or gas. I find plants from 1 to 2 feet in height are, as a rule, most useful for table decoration; but, in exceptional cases, where the tables are very large, plants 3 or 4 feet high may be employed with excellent effect. Palms for dinner-table work should be grown in small pots, a 48 pot, or

Dinner-table Palm.

at most a 32, being amply large enough for a plant 2 to 3 feet high. Much of their elegant appearance is lost if the pots are large in proportion to the plant, and the only extra labour entailed on the cultivator by the use of small pots is the necessity for watering them more frequently, especially during the dry hot summer months. If provision is made for letting the pots through the table-tops—a course as yet not very generally adopted—the size of the pots is not a matter of much consequence, since they are then concealed from view. The best soil for Palms of all kinds I find is a good fibrous loam, intermixed with sufficient sand to keep it fresh and open, and the pots must be thoroughly drained. Some cultivators add a little peat to the above, but it is not essential, except in the case of the more delicate kinds. In potting, press the soil down firmly; for, of all plants, Palms affect a stiff hearty compost, and will do far better in it than in any light loose soil.

For a small or moderate-sized dinner-table, three plants will be amply sufficient; but at large parties, where very long tables are employed, these plants can be multiplied in proportion to the space at command. These plants form an agreeable change from floral compositions arranged in March stands, and a table ornamented with Palms can be arranged very effectively in a few minutes, while no other plants whatever equal them in the freedom and grace with which their plumose,

* This department is written exclusively by amateurs distinguished for skill in various branches of gardening.

glossy foliage springs in elegant curves from the snow-white cloth. Palms may now be purchased of any of the leading nurserymen at moderate rates, or the amateur cultivator may procure seeds and propagate his own plants year after year. By adopting the latter method, plants of all sizes may be obtained, and they will form useful permanent ornaments for the plant stove or conservatory, or even for the decoration of apartments, as practised in several continental countries, where facilities for their cultivation are less common than here at home.

Perhaps in no other class of plants can we obtain more agreeable variety than in the use of Palms if carefully selected with reference to their size and habit of growth. The Plumose section are, as a rule, best suited to our present requirements, but in practice we have repeatedly used small specimens of the Fan-leaved *Chamaedoreas*, *Livistonas*, and *Geonomas* with good results. For a small table, a tall central plant of *Latania aurea*, or *Cocos Weddelliana* may be supported on either side by a plant of *Livistona altissima*, or small plants of *L. borbonica*. Next to the elegant *Cocos Weddelliana*, we have *Chamaedorea graminifolia* or *C. elegans*, both very useful when in a young state; while nearly all the *Dæmonorops* are elegant Plumose species, admirably adapted for table work. *D. plumosus*, *D. accidens*, and the subject of our present illustration, *D. fissus*, being the best. *Geonomas* are very compact and useful, several of them forming miniature stems, something like *Chamaedoreas*, but much dwarfer. Our illustration also shows the application of the new enamelled vases, which associate well with the other dinner table ornaments, or are pretty additions to the side-board in ordinary apartments. In practice, if ornate vases are not to hand, it is generally best to surface the pots with fresh green Moss, or *Selaginella*, or Drooping Fern fronds can be inserted round the sides, so as to hide the dull red mass of earthenware, or the pot can be wreathed with green and variegated forms of Ivy, *Periwinkle*, or the fresh young growth of *Myrsiphyllum asparagoides*. Amateurs, like myself, will, I am quite sure, find Palms a most tractable class of plants, and they come in for many useful purposes besides that of table decorations. I append a list of some of the best and most easily grown Palms for indoor decorative purposes:—

<i>Areca</i>	<i>Chamaedorea</i>	<i>Geonoma</i>	<i>Martinezia</i>
<i>alba</i>	<i>lunata</i>	<i>Martiana</i>	<i>Caryotaefolia</i>
<i>Catechu</i>	<i>microphylla</i>	<i>pumila</i>	<i>Lindeniana</i>
<i>lutescens</i>	<i>Sartorii</i>	<i>Schottiana</i>	<i>Maximiliana</i>
<i>monostachya</i>	<i>Wendlandii</i>	<i>Guilielma</i>	<i>regia</i>
<i>Calamus</i>	<i>Cocos</i>	<i>speciosa</i>	<i>Morenia</i>
<i>asperrimus</i>	<i>Weddelliana</i>	<i>Licuala</i>	<i>corallina</i>
<i>Hystrix</i>	<i>Dæmonorops</i>	<i>elegans</i>	<i>fragrans</i>
<i>Lewisianus</i>	(<i>Calamus</i>) <i>acci-</i>	<i>peltata</i>	<i>Oncosperma</i>
<i>melanochaetes</i>	<i>dens</i>	<i>Livistona</i>	<i>Van Houtteana</i>
<i>Carludovica</i>	<i>plumosus</i>	<i>altissima</i>	<i>Phoenix</i>
<i>rotundifolia</i>	<i>fissus</i>	<i>borbonica</i>	<i>reclinata</i>
<i>Ceratolobus</i>	<i>Elaeis</i>	<i>humilis</i>	<i>sylvestris</i>
<i>glaucescens</i>	<i>Guineensis</i>	<i>Jenkinsiana</i>	<i>tenuis</i>
<i>Chamaedorea</i>	<i>Geonoma</i>	<i>Malortiea</i>	<i>Rhapis</i>
<i>elegans</i>	<i>congesta</i>	<i>humilis</i>	<i>flabelliformis</i>
<i>Ernesti Augusti</i>	<i>elegans</i>	<i>simplex</i>	<i>humilis</i>
<i>glaucifolia</i>	<i>ferruginea</i>	<i>Mauritia</i>	<i>Welfia</i>
<i>graminifolia</i>	<i>macrostachys</i>	<i>flexuosa</i>	<i>regia</i>

GARDENING IN AMERICA.

WHOEVER comes to America, thinking to find there gardens as pretty and as well-laid out as are to be found in Britain, will be disappointed. Everything is done in America on the spur of the moment, as cheaply as possible, in a temporary way, and only with a view to the enjoyment and satisfaction of the present proprietor. Draining, especially, is very badly done; every one is his own landscape-gardener, and hot-house building is performed in a miserable, though economic, manner. As an example of the way in which glass-houses are erected in the United States, I may mention that I lately visited the establishment of one of the wealthiest nurserymen in Philadelphia, where there are a great many hot-houses of all kinds, and where the proprietor informed me that he built all the houses himself, adding, that he never had a tradesman near his place. The houses are lean-to's, and, in forming them, the ground had been levelled a little, and about 8 inches taken out to accommodate a plank that supports the lower end of the rafters; then trunks of trees with the branches pruned off are sunk at the back, one end in the ground and the other end as high out of it as the height of the house is required to be. These posts are about 8 feet apart, and the space between them is boarded up, an operation which finishes the

back wall. The rafters are made into shape with an axe, fixed to the back wall and to the plank on the ground in front, and spars are laid across them. The house is now ready for glazing, and, as the glass is bought cut and ready, it is soon fixed. The ends of the houses are boarded, not glazed, and no interior staging is required. The house it will, therefore, be seen, is now complete. When working inside of such houses, it is necessary to stoop, and, if the workman requires to straighten his back, he must kneel down to do so. I visited another famous nursery at Philadelphia, in which large portions of the roof were stuffed with Sphagnum where the glass had been broken, and the piping was laid along the passages in a zigzag form, necessitating, in passing along, the stepping from one bend to another. In these hastily-built houses, however, I observed some very fine plants, both as regards culture and quality. These ready-made houses prevail, with a few exceptions, throughout all the States, and in them good results are obtained; indeed, in a nursery, in a thriving manufacturing town in Indiana, where I acted as manager, I had in a few frames and a range of these lean-to houses, annually several thousands of fine Roses, and an incredible quantity of Pelargoniums and other plants. Fine Crotons, Dracænas, Dieffenbachias, and other fine-foliaged plants that gladden the indoor gardens of Old England, are comparative rarities in this country, and, as the majority of Americans know little about them, they only want what they do know, and what is gaudy. Camellias, Tuberoses, Lilies, Bouvardias, Myrsiphyllum asparagoides, Roses, and Pelargoniums are the greatest favourites with most people here. Nevertheless, I can see that Orchids and other European treasures in that way are gradually finding favour with us. Before an American buys or cares for a plant he must see it in perfection, and be impressed with its worth and beauty. There is, however, a grand dépôt of fine plants at South Amboy in the nursery of Mr. Such, which is quite an English nursery, and a very extensive one. Here I met with the finest specimen Orchids I ever saw, and a larger plant of *Adiantum Farleyense* than I remember having seen in the old country, whilst other Ferns, Palms, and miscellaneous stove and greenhouse plants are equally fine. Mr. Taplin, an intelligent and excellent cultivator, is manager for Mr. Such. As regards myself, I have the good fortune now to be in a private garden, which will soon be one of the finest plant establishments in the States. We have good houses, and my employer, a thorough business man, has taken an ardent fancy for Succulents, and for all the finer kinds of indoor plants, but, as the place is quite new, we have, as yet, only a limited number. My employer is, however, sparing neither pains nor money to make his plant collection complete. We have a fine plant of *Adiantum Farleyense*, and over two hundred tree and other Ferns, twenty varieties of Marantas, ten of Dracænas, twenty-five of Orchids, four of which are now in bloom; also about one hundred Camellias and Azaleas, over thirty varieties of Agaves, some of the newest kinds of double Fuchsia, and many other plants, to which additions are continually being made, not only from neighbouring, but also from European, establishments. I may add that we have lately had 24° of frost.

New Jersey, Dec. 2nd, 1873.

GARDEN DESIGN.

LANDSCAPE GARDENERS *VERSUS* ARCHITECTS.

THE relation between the architect and the landscape gardener has always been unsatisfactory; we are not surprised, therefore, to find an architect opening up the delicate question in last week's *Builder* :—

The danger to which I advert is the insidious encroachments of the landscape gardener upon the domain of the architect. It is true this is no new thing, but the encroachments have of late become more daring than before, and it behoves architects to put themselves upon their guard. The profession of the engineer has grown up chiefly through the extraordinary development attained by the railway system in this country, and however much architects may lament the fact, there can be no dispute that the engineer has fairly won the position he has acquired, and that he supplies a want which the architect was not fitted, either by taste or education, to supply. But this is not the case with the landscape gardener: his functions are essentially different from those of the architect, to which they are usually and properly subordinated, and there need not be any jealousy or any question as to jurisdiction between the two. Some landscape gardeners have, however, assumed the title of landscape architects, a palpable misnomer, which can only have been assumed to mislead, and have taken upon themselves to design and carry out buildings in addition to their other duties. The public, little accustomed to discriminate, are deceived by the assumption of the name of "architect," and the landscape gardener is not unfrequently entrusted with commissions for works of importance, to the manifest

injury of the architect proper. It may, perhaps, seem idle to complain of the preference of the public for these irregular practitioners, seeing that, as already observed, there is no recognised standard of architectural education, and that anybody is entitled to call himself an architect, and to carry out any work that he may be able to obtain; but that is not the point to which I desire to direct attention. It is, of course, impossible to coerce the public taste, and to lay it down as a rule that none but properly qualified men should be employed upon architectural works; that is clearly impracticable in the face of the attitude of the present Government, whose action with regard to architects is not only countenanced, but applauded, by the majority of people in this country. We must be content to take things as they are, and for the most part we have become accustomed to the present position of affairs; but the new danger consists in this, that while hitherto architects and landscape gardeners have been in the habit of working side by side upon the same work, without any risk of interfering with each other, it is now impossible for the architect to call upon the landscape gardener for his assistance, or to acquiesce in his appointment, without introducing at the same time a rival who may take away the most profitable portions of his work, interfere with his most cherished designs, or, perhaps, supplant him altogether. This could not have occurred under the old *régime*, but it does happen now, and the sooner architects become alive to the danger they incur in thus acting the better it will be for all parties. It comes about in this wise. An architect has prepared designs for a mansion, let us say; the site is bare and unadorned, and the client determines to employ a landscape-gardener to lay out the grounds. The landscape-gardener prepares a plan, showing not only the arrangement of the grounds, but terraces, conservatory, garden-walls, lodge, entrance-gates, stables—in fact, everything necessary for the completion of the mansion and its surroundings. This is submitted to the client, who is in all probability ignorant of the distinction between the duties of the architect and landscape-architect, the design is approved by him, and the landscape-architect is entrusted with the execution of the work. The architect is not, perhaps, consulted at all, or if he is consulted and objects, the landscape-architect makes the plausible suggestion that as he will have the control of the roads and paths, walls, &c., it will be desirable that the buildings which adjoin should also be placed in his hands; perhaps he suggests that the main building itself has not been properly treated, or that the expenditure has been excessive, or that he has carried out similar works for the Marquis of Blank, or Sir Humphrey Chose, and the client, as we have before said, ignorant for the most part of the practice in these matters, and dazzled by the achievements of the landscape architect, acquiesces, although perhaps reluctantly. It is not the mere loss of business to the architect which is to be looked to in this proceeding, although that is not to be disregarded; but it is to be borne in mind that it is in the power of the landscape gardener to interfere greatly with, or, perhaps, entirely destroy, the effect of the architect's design. The mansion may be Gothic, and the lodge classic, or, *vice versâ*, the stables may dwarf the house; and it is also always in the power of an unscrupulous man to put his rival's work in the shade, or by means of colour, outline, or juxtaposition, to enhance the effect of his own compositions at the expense of his coadjutor's. This is not an illusory picture, and the danger is real and threatening. The remedy is in the hands of architects themselves; let them take care not to associate themselves with landscape architects, but choose a landscape gardener of the old type; let their respective duties be clearly explained to the client, and, if necessary, defined in writing; and, above all, let the architect assert his authority, and insist that all drawings, for whatever works, shall be submitted for his approval before being put in hand. This is the architect's proper position, and if he abdicates his right to being consulted upon everything relating to the house and its surroundings, he will inevitably lose the confidence of his client, and will find himself immersed in numerous unnecessary difficulties.—CIVIS.

OBITUARY.

THE announcement which we have this week to make of the death of Mr. Charles Lawson, ex-Lord Provost of Edinburgh, which took place on the 21st ult., will take few by surprise, though it will be received with general regret. Far advanced in life as he was, Mr. Lawson no doubt suffered severely in health from the anxieties connected with recent commercial misfortunes. For some eight months past he has been so enfeebled as to be quite incapable of any exertion. A shock of paralysis which he experienced about three weeks ago reduced him to a still more helpless condition. The paralytic seizure recurred on Saturday the 20th ult., and from this attack he never rallied, but slowly sank. He was born in 1794, and had, therefore, at the time of his death attained the ripe age of seventy-nine. He was the son of Mr. Peter Lawson, the founder of the firm in connection with which the name was destined to become so well known, not merely in Scotland, but throughout the world.

THE KING OF THE OAKS.

WHERE is the largest Oak tree in this country? There are many claimants; and, in the confusion of measurements—for, although they are frequently given, we are not always told at what height above the ground they have been taken—it is by no means easy to arrive at a certain conclusion. The third Lord Holland, whom Sir Walter Scott describes as of so bright and cheerful a temperament that “he came down stairs every morning looking as if some special stroke of good fortune had befallen him,” must have looked his brightest when he announced to his guests at the Ampthill breakfast-table—“I have just heard that Lord Bagot’s tree has been blown down, and now I have the largest Oak in England.” Lord Bagot’s Oak was at Blythefield, in Staffordshire. The rival tree still exists, and still bears its coronal of leaves and its few Acorns. This is the Oak which is mentioned in the current number of the *Quarterly Review*, where, by some oversight, it is described as in the grounds of Holland House. It is really in the park of Ampthill, in Bedfordshire; where the verses quoted by the reviewer may still be read, fastened on the gigantic trunk:—

Majestic tree, whose wrinkled form has stood,
Age after age, the patriarch of the wood;
Thou who hast seen a thousand springs unfold
Their ravelled buds, and dip their flowers in gold,
Ten thousand times yon moon relight her horn,
And that bright star of evening gild the morn,
Gigantic Oak! thy hoary head sublime,
Erewhile must perish in the wreck of time
Should round thy head innoxious lightnings shoot,
And no fierce whirlwind shake thy steadfast root;
Yet shalt thou fall, thy leafy tresses fade,
And those bare scattered antlers strew the glade.
Arm after arm shall leave the mouldering bust,
And thy firm fibres crumble into dust.
The muse alone shall consecrate thy name,
And by her powerful art prolong thy fame,
Green shall thy leaves expand, thy branches play,
And bloom for ever in the immortal lay.

These lines are ascribed by the *Quarterly* reviewer to Rogers. We had always supposed them to have been written by Wiffen, the translator of “*Garcilasso de la Vega*,” who was much at Ampthill and at the neighbouring Woburn, and who has hung a garland of his certainly not immortal verse on the Oak tree in Woburn Park, which served as a gallows for the last unfortunate abbot. However this may be, the lines provoked a deserved retort from the late Lord Wensleydale, who made Ampthill his home:—

I’ll bet a thousand pounds—and time will show it—
That this stout tree survives the feeble poet.

This Oak, and its brothers scattered over the picturesque park, might well call forth the powers of a greater poet than Rogers or Wiffen. Ampthill stands on a ridge of high ground, overlooking the broad level of Bedfordshire—the plain of the Ouse. The ridge, so great is the contrast between it and the low country, and so wide are the prospects commanded from it, was not impossibly the prototype of Bunyan’s “*Delectable Mountains*.” The park of Ampthill extends over the sides and summit of the rising ground, and its sweeping glades and hollows, with much wood of later growth, display a greater number of venerable Oak trees than, perhaps, any other park in England of the same extent. They are for the most part shattered and wind-rent, and the sward beneath them is covered with broken fragments; but their main branches are still green and vigorous, and like the famous Oak of Yardley Chase—

The spring
Finds them not less alive to her sweet force
Than yonder upstarts of the neighbouring wood.

The two largest trees are near the house. They are nearly of the same girth—a little more than 35 feet at about a yard from the ground. But the tree which the poet has celebrated is by far the more striking of the two, and is marked by one long lateral bough which stretches nearly at right angles from the main stem, then dips sharply to the ground, and again rises. This Oak is full of leaf, and is, perhaps, more noticeable for its huge short bole and its indication of great age than for picturesque growth. Like other Oaks in the park, it has been pollarded, but at some very remote period. Of the age of these trees it is difficult to speak with even an approach to certainty. Dr. Hooker, we have been assured, has pronounced that they have not seen more than five centuries, but they had long passed their prime in the days of the Commonwealth, when a survey was made of the timber in Ampthill Park, and it was declared to be unfit for naval purposes. We may at any rate be quite sure that these venerable Oaks have many a time cast their shadow on Queen Catherine of Arragon, during her tenancy of Ampthill; and it may have been under the greatest of them that, during a hunting party held here before the coming of the unhappy

Queen, the Bishop of Paris and “*Mdlle. Anne*” were posted, each with a cross bow, waiting for the driving of the deer towards them. King Henry was himself in the heat of the chase. The bishop, in a letter to his own court, describes the scene and his conversation with Anne Boleyn—who, he adds, had made him a present of a hunting cap and frock, a horn, and a greyhound. The old castle of Ampthill stood on the highest ground in the park, looking far and wide over the masses of greenwood at its feet to the wide plain of the Ouse, fading away into a blue distance.

Leaving for the moment the question whether this Ampthill Oak is in truth the king of English forests, we may cross to the border of the neighbouring county of Northampton, and, penetrating the thickets of Yardley Chase, find our way to the Oak sung by Cowper, who, by the way, is not quite accurate when he talks of it as—

Survivor sole, and hardly such, of all,
That once lived here, thy brethren, at my birth.

Three large Oaks remain in an open “lawn”—to use the true forest term—near a farm in the midst of the Chase. The space is nearly level, and is fringed by younger growth; and the three giants stand out picturesquely as in a green “court” of their own. The largest and most shattered tree is Cowper’s. On it is fastened a gracefully apologetic warning—“Out of respect to the memory of the poet Cowper, the Marquis of Northampton is particularly desirous of preserving this Oak. Notice is hereby given that any persons defacing or otherwise injuring it will be prosecuted according to law.” The tree is a ruin, with hollow trunk—

that seems
An huge throat, calling to the clouds for drink.

broken through below and capable of holding many persons. There are two or three bare limbs, from which the bark has fallen, showing like whitened skeletons against the Lichened and knotted rind of the trunk, and there are at least two large boughs which still send out their clusters of green leaves. The trunk is not lofty, and is not more than 30 feet in circumference at a yard from the ground. But the tree is a study for an artist, and its condition is wonderfully suggestive of the long course of time since it put forth its first feeble leaflets:—

Thou wast a bauble once; a cup and ball
Which babes might play with; and the thievish jay,
Seeking her food, with ease might have purloined
The auburn nut that held thee, swallowing down
Thy yet close-folded latitude of boughs
And all thine embryo vastness at a gulp.

Many large Oaks are scattered through Yardley Chase, and two called “*Gog and Magog*,” are of especial size. But none claim to be the largest Oak in England; and although the great existing forest districts of this country—New Forest, Dean, Sherwood—abound in stately trees and in Oaks of vast girth and great evident antiquity, there is no known tree in any one of them of which the dimensions exceed those of the Ampthill Oak. For true Oak character indeed, and for the charm of deep untrodden greenwood, we must penetrate the recesses of the New Forest or Sherwood glades, where the great trees rise by thousands from a golden “lair” of Brake Fern, where the light quivers under the leafy vaulting, and where the scene is still much the same as in the days of Robin Hood or Clym o’ the Clough. But the largest remaining English Oaks stand comparatively alone, like that at Newland-on-the-Wye, which is said to measure 40 feet at a yard from the ground, and like that which we have reserved to the last, and which we believe to be in the truth the largest and most venerable Oak in this country—the Cowthorpe Oak, in Yorkshire.

This gigantic tree stands about a bowshot north-west of Cowthorpe Church, in a meadow on the right bank of the River Nidd. Its true measurements are as follow:—Circumference, at 5 feet from the ground, 36 feet 3 inches; close to the ground, 60 feet; extent of the principal branch (propped for safety), 50 feet 6 inches; girth of this branch close to the trunk, 10 feet; height of tree including decayed wood, 43 feet. In 1776 the height of the tree was 85 feet. An enormous bough, which extended 90 feet from the trunk, fell in 1718; and the owner of the tree, Mr. Montague, of Ingmanthorpe Hall, possesses a table made from this wood. Like that of the Ampthill Oaks, some of which has occasionally been used, it is full of knots and linings, and from its great hardness takes a very high polish. It may be added that the box in which the freedom of the city of York was presented to Lord Brougham was made of Cowthorpe Oak. The tree is a wonderful ruin, such as no words can fairly describe. It is a hollow tower into which you enter by an opening at the side, and the great ribbed masses of the trunk sweep round—the tree has twisted in its growth toward the south-east—in unexampled grandeur, resembling more than anything else the clefts of a sea-worn sand-rock. The sun-light falls through narrow openings, and flecks the interior of this literally

"worm-eaten hold," the colour of which, in the more shattered portions, is a deep umber. High above your head the blue sky—we last saw the Oak on a clear autumn day when the sky was cloudless—seems to roof in the tower, round the summit of which clusters a coronal of green leaves, still borne by the outer boughs. No silver Lichens or branching Polypody hang from this grandest of Oaks. The expression is that of the highest dignity, and of a strength almost unrivalled—a majesty that "smiles in death." Professor Burnet ascribed to this tree an age of 1,600 years; and if he is correct what changes it has witnessed—what worlds of thought and of feeling have passed away since the acorn fell from the old barbaric Oak, its parent? Its young boughs may have trembled to the march of Roman legionaries; it was a stately and even an aged tree before the first Christian missionaries arrived in Northumbria; it was extending all its wealth of boughs over the surrounding croft long before the first stone was laid of the adjoining church; and it has seen that church, like itself, crumbling into slow decay:—

Oh, couldst thou speak,
As in Dodona once thy kindred trees
Oracular, I would not curious ask
The future, best unknown, but at thy month
Inquisitive, the less ambiguous past.

—Standard.

[We are by no means certain that the Cowthorpe Oak, which we have seen, is the largest Oak in England; a very great width at the base is not the right test of the size of an Oak; the best place, if we are to measure at a given spot, is at five or six feet from the ground. Will any correspondent kindly tell us which is the biggest Oak in Warwickshire! If it has not the biggest Oak in England it certainly has more fine Oaks than we have seen in any other county.]

THE FUTURE OF THE ROYAL HORTICULTURAL SOCIETY.

WHAT is to be the upshot of all the agitation that is going on in the horticultural world—or, rather, amongst those connected with the Royal Horticultural Society?—a question that must be occurring to many besides myself, and one that requires careful consideration. If we are to believe what report says, the society is in a complication of difficulties of long standing. There are evidently a variety of schemes afloat for setting it to rights, but without either unanimity of purpose or action. In fact, it would appear that there are a number of cliques, each agitating on its own account for a something, and, as regards several of them, it is by no means apparent what that something is. We are weekly made aware of the existence of Mr. G. F. Wilson's clique, proposing the reduction of the fellows' subscription to a guinea, as a certain restorative; also, I believe, advocating removal from South Kensington; but Mr. Wilson does not state where he would take the society to. According to Mr. Wilson's statement, there is a clique of "competent agriculturists in London engaged in the work of reconstruction." Reconstruction of what? for I am not aware that any London society has as yet actually fallen to pieces; therefore, what does this reconstruction mean? Perhaps this clique meditates turning the present Council out in February, and the reconstruction means putting themselves in their places. If so, it would be well to know who these "competent horticulturists" are, and what their subsequent policy would be. Then, there is the vote-by-proxy clique, who, I believe, have requested the Council to summon a meeting of the fellows—to do what? Why, "to make a bye-law to give the power of voting by proxy." Now, if I read the charter aright, the fellows do not possess the power of making a bye-law at all; consequently, the meeting will be a futile one, independent of the fact of a similar proposal having already been negatived once this year. A clique of horticulturists which existed a short time since, called the Horticultural Defence Committee, took upon themselves (in conjunction with another clique, I believe) to go as a deputation to her Majesty's Commissioners—so the Defence Committee's report stated; but (query), did they not merely go to her Majesty's Commissioners Office. However, be this as it may, What did they go to do? Nothing but mischief, for they possessed no power to make arrangements with her Majesty's Commissioners, even if met by them, nor had they any authority from any one to attempt to do so; in fact, this movement on their part looked to me very like the rank and file rushing over to the enemy's camp without either the presence or authority of an officer, simply to be caught in a snare prepared for them. I read a proposal to build a club-house at Chiswick, for the convenience of the country gardeners, as a meeting place, &c.; this seemed to be in connection with Mr. Wilson's guinea scheme. Then there is what is called the Kensingtonian clique, a large and wealthy clique, too, and one that contributes largely to the Society's funds, who, it is said, desire that the South Kensington Gardens should be kept in first-rate order (at the society's expense) for themselves

and their friends to play croquet in; with frequent flower-shows, and band playing for their own, their children's, and their nursemaid's amusement. All these cliques are apparently pulling in different directions, the more they pull and waste their strength, or, in other words, the more they squabble and disgust the subscribing fellows, and consequently fritter away the society's means, the better, I guess, it will be liked by the mightiest clique of all—her Majesty's Commissioners, who, under these circumstances, will have simply to bide their time, and let these cliques go on fighting till, like the Kilkenny cats, there is nothing left but their tails; then they will be able to walk quietly in, and swallow up what little remains, and all they had been fighting over. This, I fear, will be the upshot of matters connected with the Royal Horticultural Society if we don't mind. I am not aware if any of these cliques have consulted the Council, which is the only body possessing any power to make arrangements with her Majesty's Commissioners or anyone else; whether this body is unanimous upon a policy, or is also divided into cliques, I know not; but it is whispered that they, too, either in their corporate or individual (a mode of proceeding as ruinous as the Defence Committee's) capacity, or both, have in some way or other endeavoured to induce her Majesty's Commissioners to come to some arrangement, if this be so, in which way, and with what objects in view? it is the duty of every fellow to make himself acquainted; and the duty, also, I take it, of the Council, in a business-like and straight-forward manner, to inform us; and not to follow the example of the previous Council of trying to sell us, and then expecting us, without consideration, to vote upon the instant the confirmation of the warrant for our own execution. If there are a few independent fellows who take an interest in the society's welfare, and who are desirous that it should be preserved intact, and that it should maintain the position which the Royal Horticultural Society of England ought to occupy; moreover, that it should be free to manage its own affairs, financial and otherwise, free, in fact, from all foreign control, and free to expend its income for the promotion of the science of horticulture, I say, if there are some who have not formed themselves into party cliques, but are desirous of promoting these views, it is time that they should come forward and sign a requisition also, requesting the Council to call another meeting (or to arrange for the continuation of the one already called), not to consider an isolated question, which can be brought to no issue, but to consider what can best be done to reinstate the society in an independent and prosperous position; at the same time, soliciting the Council to state plainly their views and policy, and to assist them in solving the problem. I cannot bring myself to believe that her Majesty and the Royal family can really intend to desert the society, the prosperity and maintenance of which at South Kensington formed a part of the late Prince Consort's scheme, both for the promotion of the science of horticulture in conjunction with other sciences there, and for the adornment of the Kensington estate. There can be no two opinions, I think, as regards the desirableness of coming to "satisfactory" arrangements with her Majesty's Commissioners, if possible; but what those arrangements should be require mature consideration, and I maintain that the whole body of the fellows should be consulted and given ample time to consider. We must bear in mind that we possess, for nineteen years, the control of most valuable property, property, too, that her Majesty's Commissioners want at once; in fact, bad as our affairs are said to be, I believe we possess the means of inducing her Majesty's Commissioners to come to us (instead of our going to them), and with such an offer of terms that would enable the society to maintain an honourable and independent position, and at South Kensington too. But if her Majesty's Commissioners will not meet us upon fair and honourable terms, then let us keep them out of every inch of ground belonging to us, and make no temporary arrangement whatever with them.

Stoke Newington.

WORK FOR THE WEEK.

PRIVATE GARDENS.

Flower Garden.—The chief attractions belonging to outdoor gardens at present are winter Aconites, Jasmines, and Christmas Roses, together with a few miscellaneous flowers that have been tempted to expand. Both evergreens and Grass have also an unusually fresh look for this season of the year. Unless, however, cleanliness and tidiness are maintained, the most charming arrangement cannot be in itself satisfactory; therefore, in order to have a garden enjoyable, the roller, broom, and rake must be frequently at work. Use the hoe amongst growing plants, for a loose and open surface is congenial to their health. Prune deciduous shrubs; but the pruning of evergreens should be deferred until spring. All kinds

of trees may still be transplanted, especially such as are deciduous. Proceed with any alterations that may have been previously determined upon. Any ground yet unturned should be dug over as soon as practicable; if for Dahlias, Foxgloves, Hollyhocks, or other strong-growing gross-feeding plants, add plenty of manure; but if for Pelargoniums, or other plants that are required to produce abundance of flowers and to keep dwarf in growth, a dressing of leaf-mould will be more beneficial. Lay up the ground quite roughly, in order that the frost, wind, and sun may ameliorate and sweeten it; well pulverised soil is greatly superior to that newly dug. Break up the surface of gravel walks, but not so deeply as to disturb the rubble in the bottom; and, if necessary, apply a coating of fresh gravel. Roll Grass verges, so that they may not appear too high above the gravel when cut. Protect all tender plants with mulchings and temporary light coverings against frost.

Bedding Plants.—Pelargoniums must still be kept rather dry, with the exception of a few plants of them which should be placed in an intermediate house and moderately watered, in order to induce them to make young wood for propagating purposes. Keep all the finest-leaved kinds, such as tricolors and bicolors, near the glass, in light airy pits or greenhouses, and give them sufficient water to prevent them from flagging. Verbenas, Ageratums, Salvias, Tropæolums, and similar plants should be cleared of all decaying leaves, and dry wood-ashes or sand should be scattered over the surface of the soil in the pots or boxes that contain them. If the stock of them is short, introduce a few plants to a warm house, give them a fair quantity of water, and they will soon produce young wood, which may be made into cuttings. Indeed, from this time till the end of April, Verbenas, Ageratums, &c., may be forced and propagated in large quantities, for the cuttings root readily, and soon furnish tops and side-shoots which may be used for a similar purpose. Sow some Lobelia seeds in heat, and prick off the young seedlings as soon as they are fit to handle into pots, pans, or boxes containing light sandy soil well mixed with sifted leaf-soil. By sowing Lobelias, pricking them timely out, and pinching them a little before planting-out time has arrived, they will bloom early and long. Cuttings of Lobelias may also be inserted as soon as convenient. Leave Gazenias undisturbed till March, it being then soon enough to propagate them; for early-struck plants become long and weakly before they are planted out, unless a good deal of room and pains can be devoted to them. Calceolarias in frames and boxes should be well ventilated in fine weather, and all decaying matter removed from amongst them. Remove the points of any shoots that are growing too rankly, and prepare cold frames for purposes of propagation next month. Calceolarias strike as well in cold frames if inserted in early February as they do if inserted in October; but, if the operation is delayed till March, they require a little heat to induce them to root readily. Any kinds of Dahlias that are scarce may be started in heat at once, and cuttings of them may be taken off and rooted as soon as they can be obtained; next month, however, or even the 1st of March, is soon enough for starting the general stock. If a good stock of *Caladium esculentum* be required, start some of the rested plants in a brisk bottom-heat, and, when they have begun to grow, remove the top and insert it as a cutting, still retaining the old root-stocks in the plunging material. Before long the latter will push forth a numerous progeny of young shoots, which may be separated individually after they form a leaf or two, and used as separate plants. Rub over the incision with powdered charcoal, in order to counteract damp, and return the root to the position which it formerly occupied, keeping it there until it has exhausted every effort to produce another offset. Seeds of sub-tropical plants, such as Solanums, Wigandias, Ferdinandas, Uhdeas, &c., should be sown in heat as soon as possible, in order to have good strong plants before bedding-out time; and all old plants of these genera wintered in pots should be plunged in bottom-heat, in order to produce young shoots to be used as cuttings. Prune back Hibiscuses, Cassias, Fuchsias, Abutilons, and similar plants, so that they may begin to grow slowly and hardily. *Acacia lophantha*, raised from seeds sown now, makes good plants before May for mixing with other plants in small beds. Keep *Centaureas* rather dry than otherwise, in open airy houses or pits near the glass, and remove every particle of damped-off leaves that may be hanging about them, sprinkling powdered charcoal or dry wood-ashes about their necks and over the soil. *Echeverias*, and other succulents, treat like *Centaureas*, with which they are equally, if even not more, hardy.

Conservatories.—Use only fire-heat enough to expel damp and frost, and no more; and when for the former ventilate the house at the same time. Maintain a temperature of 40° at night, with the usual daily rise. Water all evergreen plants moderately, and keep deciduous ones nearly dry. Plants in borders require watering very seldom at this season, there being but little demand upon the roots at this time of year; but pot plants, especially such as are near hot-

water pipes, require unremitting attention as regards water, for although apparently moist on the top the soil in the bottom of the pots may be dry. Such a condition would be extremely detrimental, as the greatest amount of roots is amongst and over the drainage. Rather than keep the conservatory too warm, in order to forward the plants therein, supply any deficiency there may be in the way of flowers by means of Camellias, Azaleas, Jasminums, Weigelas, Kalmias, Prunuses, Acacias, Dielytras, Lily of the Valley, Dutch and Roman Hyacinths, Tulips, Narcissi, Crocuses, and other plants from the forcing pits. Decaying leaves must be regularly removed, and a rather dry and healthy atmosphere is a good remedy for such an evil, and to effect this supply artificial heat and plenty of air. Keep Heath, Epacris, Chorozeas, Boronias, Tremandras, &c., in the coolest and freest ventilated portion; and forced shrubs and other flowers, Orchids, &c., in the warmest parts. Cut over Chrysanthemums that have done flowering, and keep a pct of each kind in a frame, if sufficient cuttings have not already been obtained. Plant the others in the open border, or, if not wanted out of door hrow them away. Shift herbaceous Calceolarias and Cinerarias as they require it, and keep them cool and well watered; never permitting a damped or decayed portion of a leaf to remain. Fumigate to destroy aphids, and keep in mind the old maxim, "prevention is better than cure." Keep Mignonette near the glass, and stake and tie it as may be necessary. Have a good succession of it, Violets, and other plants, in pits. Regularly train Tropæolums, and give them a little manure-water if they are making good progress. Continue to pot off singly good rooted early autumn-struck cuttings of Azaleas, Camellias, &c., but if neither time nor space can be spared for shifting them at present, leave them for a time in their cutting pots set on a side-shelf of a close pit or intermediate house. Any Statice becoming too long-stalked should have an incision made on each branch just at the base of the foliated crowns, after which some Moss should be tied around it. The Moss should always be kept damp, and if a little silver sand is mixed with it so much the better, as it helps to encourage root-production. Keep old and young Statice moderately moist and in a minimum temperature of 45°. Pot off cuttings of Libonias and keep them for a short time in a warm pit, and when root action again begins, transfer them to an intermediate house. Divide the rhizomes of the variegated-leaved *Acorus javanicus*, and keep the divided portions for a time in gentle heat. From male Aucubas in flower gather the pollen and keep it dry between bits of glass for future use. Start into growth, in a warm pit, tropical Crinums. Re-pot and start some *Hæmanthus*es; they may be placed upon the floor in a warm house or pit, or on a back shelf.

Hardy Fruit and Kitchen Garden.—Proceed with the pruning and nailing of wall-trees, such as Plums, Pears, Cherries, and Apricots. All standards, if not already done, should be pruned as expeditiously as possible, and old unfruitful trees removed to give place to younger ones. Moss growing on the stems of old trees should be scrubbed off, and afterwards the trees and large branches should be washed with a mixture of lime-water, soot, and brine. Root-prune over-vigorous trees, taking care not to encroach too severely on the roots. Cut off shoots to be used as scions in grafting, and insert their ends in soil in some well-sheltered situation. Head back stocks, for if allowed to remain without being cut until the sap is in active circulation, the bark commonly dies back a little below the wound. Freely expose Lettuces, Cauliflowers, &c., in frames in favourable weather, protecting them from frost at night. Plant out some Lettuces, at convenience, on a warm border, and prick some Spruce branchlets amongst them. Plant in dry ground Ash-leaf Kidney Potatoes, and make new plantations of Horseradish and Jerusalem Artichokes. Sow some Parsley on a sheltered spot, and protect a portion of the old plantation with a frame-sash or two, so as to permit of the leaves being gathered in frosty weather, and likewise Cauliflowers under hand-lights. Lift in Broccoli that is living with good balls, and place them in cellars or sheds to protect them from frost. Uncover Celery ridges from the mulching of litter in fine weather, as its presence would generate dampness and promote rottenness. Sow some of Wood's Frame Radishes on a south wall border, and mulch it with litter; and Early Horn Carrots may be treated the same as Radishes, and some Early Dutch Turnips may likewise be sown on a warm border. Avoid sowing anything on sodden soils, as much harm is done by so doing, and whole crops frequently lost.

Gilbert's Protectors.—I notice in the advertisement columns of the gardening press, what, I may call an extraordinary assertion on the part of Messrs. Boulton, viz.—That the judges at Birmingham gave them the only prize for protectors, when at the same meeting I was awarded a medal for Gilbert's hand-lights and protectors. Such assertions as these are apt to lead the public astray.—R. GILBERT.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

LANDSCAPE GARDENERS *VERSUS* ARCHITECTS.

By J. C. NIVEN, Botanic Gardens, Hull.

THE article which appears in your last week's number (see p. 21), in which "Civis" defines, no doubt, to his entire satisfaction, the relative positions of the architect and the landscape gardener, should not pass without comment at the hands of those whose status he somewhat rudely assails. The habit which some have of looking at things from only one point of view is tolerably well exemplified in the article in question, and, in offering the following remarks, I do so, not exactly as the knight champion of the landscape fraternity, nor as possessing the ability to define clearly, for all whom it may concern, that boundary line which separates the two professions, but merely to assert my individual opinion upon one or two matters in the article just alluded to, which, I think, ought not to pass unchallenged. Let me, in the first place, congratulate the "citizen" architect on his frank and free admission of the engineer to a fair professional recognition. I wish, when admitting the fact, that he had not qualified it by a sort of "lamentation," and hinted that he had been galvanised into existence by a sort of high-pressure railway development, but had honestly admitted that the engineer was a necessity of the iron age in which we live—a necessity which no sensible architect will, I think, deny. Remembering perfectly the onslaught which was made by the architectural journals when the construction of Westminster Bridge was placed in the hands of Mr. Page, the engineer; and admiring, as I do, the beauty of the bridge so designed and, in spite of all the ill-natured prognostications, still existent, I the more appreciate the recognition of the civil engineer's profession, and am further enlivened with the hope that at some future time the true status of the landscape gardener will be as fully recognised, and his services as highly appreciated, even by "Civis" himself, as those of the engineer. Permit me, at the outset, to demur to the somewhat novel title which some of us landscape gardeners have assumed—namely, that of "landscape architects." I have heard the title "garden architect" appended to the more general one of "landscape gardener," and a perfectly correct and intelligible addition it is, as both combined appear to define pretty clearly the work which devolves on the landscape gardener. I will now endeavour briefly to point out the respective spheres which the two professions should occupy—nay, I might almost add, do occupy, were I to speak from my own professional experience, which extends over some twenty years. Let us suppose, as in the illustrative case which "Civis" uses, that, as a matter of course, the services of the architect are called in to prepare the designs for a mansion. Here, of course, he is master of the situation; but has he not forgotten that, as a general rule, the "site" of the house—which has a somewhat important bearing on the style—is usually first selected? And here I claim the right of the landscape gardener to be heard—nay, to be fully consulted. Not only is there truth in the old adage, that "two heads are better than one," but so much of the picturesque character of the mansion depends on its surroundings, that the salient points, even "Civis" himself will admit, are more likely to suggest themselves to the practised eye of the landscape gardener than to the architect. Here, then, at the outset, let the two professionals argue out, if necessary, their *pros* and *cons*, with the client as umpire; and, the site having been determined, let them proceed on their separate courses, taking care that such courses run in parallel grooves, and not at cross purposes, in which case there is sure to be a collision. On the architect clearly devolves all the work in connection with the mansion and its outbuildings, the lodge, the gardener's house—and, in fact, any other cottage or building of that description on the estate; but, let me add that, as in fixing the site of the mansion, so, before the sites of all such buildings are finally determined upon, the landscape gardener should be consulted, as it devolves on him either to utilise them, if

ornamental, or to screen them from view if otherwise; and who more likely than he to know what are the natural advantages available for this important purpose? My practice is to indicate on the general plan of the estate, the positions for all such buildings, leaving everything else to the architect. The next point, namely as to the arrangement of terraces, terrace steps, fountains, &c., is one open to considerable difference of opinion, even amongst those of our own profession. I am clear on the matter that those immediate adjuncts of the mansion should represent the result of a happy combination of the two professions; the general lie of the ground, and the arrangement of the flower-beds, if any, should belong to the landscape gardener; the architectural details, which, of course, will be carried out in harmony with the details of the building, belong to the architect. Where the latter monopolises the whole arrangement to himself, he is not always happy in his results, and rarely is he practical, as many a poor gardener can testify to his cost. A conservatory, now-a-days, is almost invariably an adjunct to a country house, and properly so; but, as it has a use beyond its mere external appearance, namely, its true use as a means of extending and increasing indoor enjoyment, while it possesses sufficient architectural character to harmonise with the rest of the building, it ought to be equally well adapted for the growth and artistic display of plants. There should be means of maintaining a proper temperature and full power of thorough ventilation. Here it will be obvious that the grooves in which I proposed the two professions should run, again just touch one another; let the architect build the conservatory, consulting his brother professional as to the ventilation, and let the "garden architect" (here we give him his other name) complete the internal arrangement, including the disposal of the hot-water apparatus, &c. Of even more importance than the conservatory is the kitchen garden, with its forcing houses, plant-houses, and the various sheds which are necessary for the usual purposes of garden accommodation, including, of course, the walls. These belong, I most unhesitatingly maintain, to the garden architect. Here the architect, pure and simple, is out of place, just as much, and perhaps a little more, than the so-called "landscape architect" would be in dealing with the lodge or the stables, as contemplated by "Civis." The majority of our profession have been at one time practical gardeners, and thus know by experience what the essential requirements of such buildings are in all their detail. Should, however, the designing of these kitchen garden adjuncts devolve on the architect, as might possibly be necessary in the case of one or two of our most highly æsthetic landscape gardeners, I will give him one word of advice—let him not deem it beneath his dignity to submit his plans, before final completion, to the gardener, and avail himself of those practical suggestions which I will warrant he will obtain from that source.

Having thus indicated what, from my point of view, appears to be the relative position of the two professions, I have one or two points to touch upon before I bring my remarks to a close. Let me ask "Civis" for a straightforward answer to the following questions:—Does his so-called "Landscape Architect," against whom he has made out a case of professional poaching, represent the only class of poachers? Do architects never by any chance arrogate to themselves all the functions of the landscape gardener? If "Civis" declines to answer these questions, I will do so for him, after the Scotch fashion, by asking another question or two. Have we no terrace-gardens in the country where artificially variegated walks are made to wage war with the true contrasts and harmonies of nature's beauteous flowers? Have we no parterres that bid defiance to all the powers of the gardener, even with the most extensive resources, to plant successfully? I am of opinion we have, and for most, if not all, of them we are indebted to architects who have stepped beyond their calling and become poachers on the true preserves of the landscape gardener. Again, look at the hundreds of cemeteries scattered through the length and breadth of the land that have sprung into existence within the last few years. The great majority of these are illustrative of the result of architects undertaking to do what they possess no qualification for, with what result I

will not trust myself to say. The public have, in many cases, passed a true verdict, and more fully will it be endorsed by the descendants of the said public in future years, when they find that even the softening hand of time will fail to obliterate the incongruities that have been, and, indeed, are every day being, perpetrated by architects, and in many cases by architects of no mean reputation either. If I lay myself open to be challenged as speaking harshly of a profession in whose ranks I have personally always met with the most honourable and straightforward conduct, I must plead that they have been called forth by the insinuations from "Civis" derogatory to our profession. In conclusion, I would say, with reference to the "happy thought" broached by "Civis" "That the architect should assert his authority, and insist that all drawings for whatever works shall be submitted to him for his approval before being put in hand," that the profession of landscape gardener and garden architect is year by year assuming a more definite status, and, in spite of all "Civis" may do or say, will hold its own true position as independent of the whim or fancy of the "architect."

THE GARDENS OF ENGLAND.

CHATSWORTH.

(Concluded from p. 7.)

The Pleasure Grounds.

THESE, including the Pinetum, may be counted by miles, not by acres, and require a full day to pass through them, and far more to know them thoroughly. Paxton has done much; but, from an artistic point of view, he might have done more. We have seen many of his creations at Sydenham, Birkenhead, and at other places, and, with all due respect for his memory, we are bound to confess that Chatsworth, as a whole, is not the most meritorious of his works. This may not be his fault, but rather his misfortune. We all know that, with ancient families, interference with the past is more difficult than improvements for the future; and hence old landmarks must be retained, which, for real improvement, would frequently be better swept away. Many of these crop out at Chatsworth, but to detail them would be simply waste of time. Hence, much that has been done in the garden, or pleasure ground, properly so called, might have been better done. Smoothness, Burke, in the "Sublime and Beautiful," defines as one of the main elements of beauty; but in the walks at Chatsworth, especially in the strictly Paxtonian parts of the grounds, there is a want of finish and smoothness which is anything but pleasing to the eye of taste. The main fronts associated with the mansion are terraced, the retaining walls, and all belonging to them, being of the most substantial and appropriate character. Numerous specimens of vases, urns, and statuary decorate the piers, and the principal flower-beds are margined with massive stone walls of suitable design. When, in the autumn months, these beds are full of the flowers of the season, they have a brilliant effect. But bedding-out at Chatsworth is disheartening work, for the frosts are so late and so early that it is the end of June before it is safe to plant, and the end of August is certain to bring frost. However, while the beds are in perfection, the sight is a glorious one. Seen from the principal apartments, with the silvery Derwent meandering through the valley, amid fine timber, the scene is a charming one, and one which is worthy of the pencil of our greatest artists. But, fine as is the effect of bedding-plants during their transient season, it is when the garden can be seen with acres of the various-tinted Ghent Azaleas, Rhododendrons, and other American plants, backed by the variously tinted foliage of deciduous trees and the ever-grateful Hawthorns, that it crops out in full glory. Of timber trees, there is at Chatsworth a fine avenue of Limes, Spanish Chestnuts of more than usual size, and grand specimens of Oak, Beech, and Ash. Holly and Yew luxuriate there, associated with some fair specimens of Cedar of Lebanon, Wellingtonia, and the Lawson's Cypress; but the Deodar, Araucaria, and some of the tender Conifers, suffer much in severe winters. The lawns at Chatsworth are superbly kept, the turf being smooth and velvety; but, as you get away to the arboretum, less care is observed. The collection of trees and shrubs was at one time very complete; but the severe

winter of 1861 destroyed so many of the tender shrubs, that it was considered impracticable to replace them. Still, many interesting examples may be found in the three miles' walk which comprises the arboretum.

The Rock Garden.

This may be considered the ante-garden to the grand conservatory, and it is not until you get into it that you realise the Paxton idea of landscape work; and there you have a fair example of what may be effected by means of excavations, stones, and shrubs. The latter have now played an important part, having covered the nakedness of the rock-work, and, when they cover the whole, the garden will look none the worse. It was a bold act of Sir Joseph to enter into competition with nature in one of her strongest positions; and, though the conception was good, and in some respects well executed, one has only to take a run from Chatsworth to Buxton to see how futile it is for man to enter into such a trial of skill. The stone used is mainly of the boulder formation, piled together so as to form archways and rock pillars, the labour of moving such huge masses being not the least remarkable feature connected with the work. Except in the principal mass, some 30 feet high, from which drips a streamlet into a basin at its base, little attempt is made at stratification. In the strictly garden part, huge stones crop out from beds of American plants, and Ferns and some Coniferous trees play an important part in diversifying the scene. In fact, this is as much an American as a rock-garden, and the association is by no means bad.

The Plant Houses.

A collection of many hundred plants of *Epiphyllum truncatum*, and its varieties, is, at this season, one of the most remarkable features of the conservatory, to which we briefly adverted last week; while, in hanging baskets suspended in various parts of the house, they present a floral charm rarely to be equalled. Of the suitability of these plants for hanging baskets, those only who have seen them at Chatsworth can form an opinion: they are simply superb. As a non-flowering plant, nothing looks so well as the Elk's-horn Fern (*Platycerium alcinorne*), with a few *Adiantums*, and other Ferns of that kind. In their season, *Achimenes* also form a grand feature in baskets; indeed, it may be said that the baskets at Chatsworth are a feature always to be admired. Other plant-houses are numerous, and some of them of fine proportions. The Orangery, which adjoins the sculpture gallery, is a noble structure, and contains some remarkably fine trees in vigorous health. This house is, of course, architectural in character, and, when artificially lighted, and the trees are in bloom, it forms a charming promenade. From the Orangery extends a glass-cased wall of several hundred feet in length, which forms in stormy weather a very agreeable shelter. It is, however, very narrow, not being more than 6 or 7 feet wide, but we believe it is contemplated to make it 15 feet wide, and to continue it from the Orangery at one end to the plant-houses at the other, thus forming a very interesting promenade. In the central part of this case may be seen remarkably vigorous specimens of double white and other *Camellias*, which annually produce thousands of flowers. Here, upon this wall, may be seen the original plant of *Clianthus puniceus*, first shown at Chiswick by Messrs. Young, then nurserymen at Epsom, and for which the late Duke paid fifty guineas. Here, also, is one of the first plants of *Brugmansia sanguinea* and a remarkably fine specimen of *Citron*, presented by the Duke of Rutland. On this wall many plants grow with wonderful vigour. *Ugenia Ugni* yields annually a heavy crop of fruit, and we never have seen *Mitraria coccinea* in such fine condition as it is when thus protected; in short, it blooms almost continuously. The *Camellia*-house is an architectural building, perhaps the oldest in the garden. It has heavy walls pierced with windows, and the roof consists of very small glass; the plants, however, many of which are very large, are in the finest conceivable health, and produce, annually, tens of thousands of flowers. Mr. Speed's plan is to deluge them, in the growing season, with weak soot-water, and never, at any time, to let them know the want of water at the root. Adjoining this glass promenade are three ranges of plant-houses, erected some five years back. Each range is divided into

three houses; the first range consists of stoves, the second of intermediate-houses, while the third, which is of considerable size, is devoted to Orchids. One house is occupied almost exclusively with Vandas, Aërides, and Saccolabiums, some of them being enormous specimens, which bloom in the most perfect manner. The plants stand upon slate shelves covered with spar, the extremes of heat and cold in summer and winter rendering isolation from the slate necessary. This house is heated by sixteen rows of 4-inch pipe. In the cool-house will be found a fine collection of *Sarracenias* in robust condition, and also grand masses of *Cœlogyne cristata*, *Miltonia spectabilis*, *Lycastes*, and some of the hardier *Dendrobies*. Of *Dendrobium nobile* and its allies, Chatsworth has many very large specimens, and the plants *D. Devonianum* and *Dalhousianum* and some of the rarer ones are also very fine. *Phalænopsis amabilis* and *Schilleriana* will be found in superb condition, while *Pleiones* and *Calanthes* for cutting flowers from are grown by the hundred.

Stove plants are grown mainly for the sake of their blooms, in a cut state, for table decoration, hence the object is rather to keep the plants small and healthy than to produce enormous specimens, and the same may be said of the greenhouse plants.

Upon the whole, Chatsworth is a most interesting place, but no one should expect to realise its full attractions without devoting, at the least, three days to the work of inspection. The keeping of the whole place reflects great credit upon Mr. Speed, and is yearly improving under his skilful management.

THE LIBRARY.

THE NATURALIST IN NICARAGUA.*

In the beginning of 1868, Mr. Belt arrived in Nicaragua for the purpose of superintending the operations at the mines of the Chontales Gold Mining Company, situated near the village of Santo Domingo, and nearly in the centre of the republic. Here he resided for four years, during which time, in addition to the discharge of his professional duties, he employed himself in acquiring a thorough knowledge of the natural history of the country, and the manners and customs of the inhabitants. He says, "I had much riding about. The mines worked by us when I first went out extended from Consuelo, a mile higher up the valley, to Pavon, a mile below Santo Domingo, and even after I had concentrated our operations to those nearer to our reduction works, there were many occasions for me to ride into the woods. I had to look after our wood-cutters and charcoal-burners, to see that they did not encroach upon the lands of our neighbours, as they were inclined to do, and involve us in squabbles and law-suits; paths were to be opened out, to bring in Nispra and Cedar timber; our property had to be surveyed, and new mines, found in the woods, visited and explored. Besides this, I spent most of my spare time in the forest which surrounded us on every side, so that we could

not go a mile in any direction without getting into it; longer excursions were frequent. These rides and strolls into the woods were very fruitful in natural history acquisitions and observation." The result of these four years of constant and intelligent observation Mr. Belt has embodied in a handsome illustrated volume of nearly 400 pages, replete with the most useful and interesting information on the natural history and present condition of that part of Central America. Had we space, we might quote pages. We must content ourselves,

however, with the following short extracts, the first of which contains an account of the singular insects represented in the illustrations, for the use of which we are indebted to the courtesy of the publisher—Mr. Murray:—

Amongst the insects of Chontales none are more worthy of notice than the many curious species of Orthoptera, that resemble green and faded leaves of trees. I have already described one species that looks like a green leaf, and so much so that it even deceived the acute senses

of the foraging ants; other species, belonging to a closely related genus (*Pterochroza*), imitate leaves in every stage of decay, some being faded-green blotched with yellow; others, as in the species figured, resemble a brown withered leaf, the resemblance being increased by a transparent hole through both wings that looks like a piece taken out of the leaf. In many butterflies that resemble leaves on the under side of their wings, the wings being raised and closed together when at rest so as to hide the bright colours of the upper surface, there are similar transparent spots that imitate holes; and others again are jagged at the edge, as if pieces had been taken out of them. Many Chrysalides also have mirror-like spots that resemble holes; and one that I found hanging from the under side of a leaf had a real hole through it, formed by a horn that projected from the thorax and doubled back to the body, leaving a space between. Another insect, of which I only found two specimens, had a wonderful resemblance to a piece of Moss, amongst which it concealed itself in the daytime, and was not to be distinguished except when shaken out; it is the larva stage of a species of *Phasma*.

Of the effect of corrosive sublimate on ants, the author writes as follows:—

A little of it sprinkled across one of their paths in dry weather has a most surprising effect. As soon as one of the ants touches the white powder, it commences to run about wildly, and to attack any other ant it comes across. In a couple of hours, round balls of the ants will be found all biting each other; and numerous individuals will be seen bitten completely in two, whilst others have lost some of their legs or antennæ. News of the commotion is carried to the formicarium, and huge fellows, measuring three-quarters of an inch in length, that only come out of the nest during a migration or an attack on the nest or one of the working columns, are seen stalking down with a determined air, as if they would soon right matters. As soon, however, as they have touched the sublimate, all their stateliness leaves them: they rush about; their legs are seized hold of by

some of the smaller ants already affected by the poison; and they themselves begin to bite, and in a short time become the centre of fresh balls of rabid ants. The sublimate can only be used effectively in dry weather. At Colon I found the Americans using coal tar, which they spread across their paths when any of them led to their gardens. I was also told that the Indians prevent them from ascending young trees by tying thick wisps of Grass, with the sharp points downwards, round the stems. The ants cannot pass through the wisp, and do not find out how to surmount it, getting confused amongst the numberless blades, all leading downwards.

Moss Insect.

Leaf Insect.

* "The Naturalist in Nicaragua." A narrative of a residence at the gold mines of Chontales, journeys in the savannahs and forests, with observations on animals and plants in reference to the theory of evolution of living forms. With maps and illustrations. By Thomas Belt, F.G.S. London: John Murray, Albemarle Street. 1874.

NOTES OF THE WEEK.

— WE are glad to announce that the new edition of Mr. Gordon's "Pinetum" is now almost ready for the press. The book is nearly re-written, and the information on the subject brought well down to the present time.

— WE learn that the autumn show of the larger Fungi at the Royal Horticultural Society has so steadily increased in interest and popularity that it is intended to considerably extend it this year. The most useful of the edible and easily obtained kinds should be shown in some quantity, and, if possible, in a cooked state also.

— WE have just seen a batch of single and double Chinese Primroses, which have been sent by express from Nice, where they were grown by Messrs. Stuart. Nothing could be more beautiful than their varied and rich hues. They are not grown in the open air at Nice, but in cool houses as at home.

— A PLAN has been prepared, which contemplates the making of a park for Boston containing 3 square miles of territory, or about 2,000 acres, and for this the cost, with improvements, is estimated at 5,000,000 dols. The site contains small streams and a large pond of water, and it is proposed to use the water-supply in making an artificial lake and a chain of lakelets, which will give variety to the scenery.

— THERE is now a fine specimen of *Angræcum sesquipedale*, bearing twelve of its great wax-like flowers on three spikes, in the Royal Exotic Nursery, Chelsea, the plant being one of the finest we have seen. The beautiful white-flowered variety of *Lælia anceps*, named in honour of the late Mr. Dawson of Meadowbank, "*Dawsonii*," is also in flower, as is likewise a fine rosy-coloured variety of *Cypripedium Roezlii*, while a good form of the pretty little *Colax jugosus* is in bloom.

— WE are pleased to hear that *Odontoglossum coronarium* is again showing flower (two spikes) in Lord Londesborough's collection at Surbiton. This plant seems as shy in its flowering as *Renanthera coccinea*, and has, as yet, only bloomed in one or two collections in this country. Amongst other plants also in bloom in this fine collection are *Lælia autumnalis*, with seven flowers on a spike, and *L. albida rosea* with two deep rosy blooms in place of the white ones common to the species. A plant of the rare and beautiful *Sophranitis violacea* has also produced deep rosy-lilac flowers in the same collection.

— THE Royal Botanic Society of London have issued their programme for 1874. The arrangements are:—Exhibitions of spring flowers, Wednesdays, March 25th, April 22nd. Summer exhibitions, Wednesdays, May 20th, June 10th, and June 24th. Gates open at two o'clock. Special evening *fête*, Wednesday July 8th. American exhibition, daily, May 25th to June 9th. Promenades, every Wednesday in May, June, and July, excepting the exhibition days, commencing May 6th. Visitors admitted only by the special coloured orders. Lectures in the museum at four o'clock precisely, Fridays, May 15th, 22nd, 29th; June 5th, 12th, 19th, 26th; July 3rd.

— IN the January number of the *Botanical Magazine*, among other plants figured there, are three deserving of especial attention. Foremost amongst these is *Saxifraga peltata*, a native of California, a species which has great peltate-lobed leaves and erect cymes of rose-coloured or rosy-white flowers. It is found in moist localities, and grows best treated as a sub-aquatic. *Stendnera colocasiæfolia*, a dark blotched-leaved yellow-flowered Arad, also deserves mention, as does likewise *Mesembryanthemum truncatellum*, a stunted swollen species from the Cape, of a brown colour, bearing golden-rayed blossoms; and the beautiful *Colchicum speciosum*, a native of the Caucasus, also to which we have already alluded as having flowered freely during the past autumn in Mr. Barr's collection at Tooting.

— AN account of the Hull Window Garden Society just received shows that, after paying all expenses, a balance of upwards of £14 still remains in the treasurer's hands, while last year the balance was little more than £3. Upwards of ninety money prizes have been given away this year, and in addition thirty-seven prizes, consisting of articles of various kinds and values—from a bird-cage or a pair of table-spoons to a flower vase. Besides these some three hundred well-established plants for window culture have been given to the exhibitors. It is likewise stated that every exhibitor, including the little children who brought their neatly-arranged bunches of wild Grasses (and of these there were some two hundred), received some reward for his labour. It is mentioned that no plants taken from the borders have been distributed this autumn, the committee being of opinion, from previous experience, that as much pain as pleasure is given by such distributions. So many of the plants die, that the effect is often discouraging as well as disappointing; they propose, therefore, to act in future years as they have done this year, viz.:—give away, at the flower-show, as many well-established plants as

they can obtain from their friends, who, like themselves, are desirous of promoting the culture of window-plants by the working classes.

— A PLANT of *Lycaste Skinneri*, now in blossom in the Royal Exotic Nursery, Chelsea, bears two flowers on one spike, as is occasionally the case with *Cypripedium barbatum*, *C. venustum*, and its variety *C. pardinum*.

— IF we wanted proof of the hardiness of shrubby Veronicas it might be had in Miss Hassard's garden at Upper Norwood, where there are plants from 4 to 5 feet high, that have been out in the open ground this two winters, and in no way protected during the hardest frosts.

— AMONG rare tropical fruits offered for sale in Covent Garden Market we have this week noticed fine samples of the white-fruited Guava from Madeira, *Psidium pyrifera*, the fruits of which are of a pleasant sub-acid flavour.

— THE *Botanical Magazine* for January contains a figure of *Bambusa striata*, a Chinese species, having deep green stems striped with bright yellow. It grows under cultivation 6 or 8 feet high, and forms a highly ornamental plant either for conservatory or greenhouse culture.

— THE new *Clarkia*, *C. integripetala limbata*, is well figured in colours in the new issue of Messrs. Carter's seed-catalogue. It is a large full-petalled kind, with its crimson petals evenly and distinctly margined with white, and it is likely to prove a very popular garden flower.

— AT a sale at Stevens' on Thursday last, single plants of the rare and beautiful white-flowered *Odontoglossum Roezlii* realised from £5 5s. to £16. Ten thousand bulbs of *Lilium auratum*, newly imported, also fetched good prices, notwithstanding other large importations lately received.

— AT a meeting last month of the Central Horticultural Society of France, M. A. Rivière, chief gardener at the Luxembourg, exhibited a very charming specimen of a Bromeliad, not too well known in our gardens, viz., *Vriesia brachystachys* Regel., or *V. psittacina*, var. *brachystachys* Hort., which was pronounced to be unequalled amongst Bromeliads for vigour of growth and beauty of bloom.

— WHEN completed, the new park at Eastbourne will be one of the greatest improvements at that fashionable town. The ground, nearly 13 acres in extent, is to be known as Burlington Park, and is situate close to Eastbourne College. The southern part is arranged in three terraces, and will be planted with shrubs and trees of various kinds. There will be a row of Elms all round the ground, while an avenue of trees, opening from the south on to the cricket-ground proper, will form the main entrance. The cricket-ground will be nearly 6 acres in extent, and surrounded by trees. It is intended to have ornamental water in the ground. The whole expense will be defrayed by his Grace the Duke of Devonshire.

— PROFESSOR ASA GRAY, in a paper read before the American Pomological Society, makes some interesting and apt remarks as to the origin of our cultivated fruits. He asks, "Were the fruits made for man, or did man make the fruits? These," he says, "need not be taken as mutually exclusive propositions; for as 'God helps those who help themselves,' and man's work in this respect is mainly, if not wholly, in directing the course or tendency of nature, so there is a just sense in which we may say 'the art itself is nature,' by which the greatest triumphs of horticultural skill have been accomplished. Moreover, I am not one of those naturalists who would have you believe that nothing which comes by degrees, and in the course of nature, is to be attributed to Divine power. The answer I should give to the question, as we thus put it, is: 1. Some fruits were given to man as they are, and he has only gathered and consumed them. But these are all minor fruits, and such as have only lately come within the reach of civilized man, or are not thought worth his trouble. Cranberries, Persimmons, and Papaws are examples. Whether even such fruits have or not been under a course of improvement irrespective of man, is another question. 2. Others have come to man full flavoured, and nearly all that he has done has been to increase their size and abundance, or extend their season. Currants and Gooseberries, Raspberries and Blackberries, Chestnuts, and, above all, Strawberries are of this class. 3. But most of the esteemed and important fruits, as well as the grains, have not so much been given to man as made by him. The gift outright was mainly plastic, raw material, time and opportunity. As to the cereal grains, it is only of the Oat that we probably know the wild original; of Wheat there has been an ingenious conjecture, partly but insufficiently confirmed by experiment; of the rest, no wild stock is known which is not most likely itself an escape from cultivation. Of some of them, such especially as Maize, not only can no wild original be indicated, but in all probability none exists. So of the staple fruits; of some, the wild originals can be pretty well made out; of more, they are merely conjectural; of some they are quite unknown and, perhaps, long ago extinct."

THE FLOWER GARDEN.

CLIMBERS FOR CORRIDORS AND VERANDAHS.

ARCHITECTURAL features, however beautiful in themselves, are improved both in appearance and interest when judiciously associated with climbing or trailing forms of vegetation. We have many plants suitable for covering balconies and pillars that add very materially to the charms of a well-appointed garden or landscape. The remains of some of our finest abbeys and castles owe much of their beauty to the Ivy that clings lovingly to the ruined arch, or that clambers rampant to the highest point of the massive keep or donjon tower; and what the Ivy is to our old castles and churches, ornamental climbers are to our more modern dwellings. In our town gardens more especially, these graceful plants should find a place, as they require but little attention after being planted, and do much towards softening down the rugged angularities of brick-and-mortar structures, the barren nudity of which is but too obvious in our streets and squares. We have a great wealth of material at hand for such purposes. In planting climbers for covering buildings, protect them from drip from the eaves, as this is fatal to their well doing. Among the forms of vegetation best suited for pillars, balconies, arbours, or porticoes, are Roses, especially the climbing varieties, all of which are very beautiful. The common white Jasmine is a great favourite with us, and the golden-coloured *Jasminum nudiflorum* is very pretty in winter, when trained loosely up a trellis on a fresh green background of the common Ivy. One of the best of all trailing plants is the fragrant lilac-flowered *Wistaria sinensis*, which, as most of us know, blooms very freely on a sunny wall, while its foliage keeps fresh and green until very late in the autumn. We generally see this plant trained horizontally along a wall, but it is much more beautiful when trained up the trunks of Larch, Scotch Firs, or other trees, and allowed to droop down from among their branches in elegant festoons, or its long branches may be trained along the tops of palisades and railings, where it forms fresh green wreaths of foliage all through the summer months. *Aristolochia Sipho* is one of the most noble of all climbers with which to drape balconies or outer walls of town houses, but, like the *Wistaria*, it is deciduous. Those who have seen this beautiful climber on Mr. Fleming's house at Clevedon, or in the garden at Ockham, will not need to be told of the unique effect which it is capable of producing. Mulready was greatly struck with the effect produced by the plant at Ockham, where it grows most luxuriantly, and a graphic pen and ink sketch of its foliage may be seen at South Kensington, the handiwork of that great artist. The common Grape Vine is one of our noblest deciduous climbers, either for corridors or for trellises, while the American and Canadian Vines are very attractive in autumn, when their foliage changes to the brightest tints of crimson and gold. The American Fox Grapes used to grow and fruit very luxuriantly on trellises in the Royal Horticultural Gardens at Chiswick, and they are useful for covering walls or low out-houses along with the green and variegated forms of the common Ivy. *Cotoneaster microphylla* is another excellent evergreen wall-plant, which is always fresh and cheerful, either in spring when covered with snow-

white flowers, or in winter when thickly studded with crimson berries. A very pretty effect may be produced by planting the last-named plant with the golden-flowered *Jasmine nudiflorum*, as the two contrast most effectually when seen together. For town gardens few deciduous trailers surpass the Virginian Creeper which succeeds so well in the neighbourhood of London. It grows quickly, and is invaluable for covering blank walls and trellises in the shortest possible time. Its foliage is fresh and green throughout the summer, and in autumn it dies off, tinted gloriously with glowing crimson, rich brown, and purple. Its congener, the Japan Creeper, is another fine wall plant, which clings firmly to masonry or brickwork. In the Royal Exotic Nursery at Chelsea this species of creeper grows very luxuriantly, covering a cottage and other buildings with admirable effect.

For walls, porticoes, arches, and corridors, such as those represented by our illustrations (from Mr. Delamotte's charming sketches of "Holland House," published by Messrs. Macmillan), few plants are equal to *Clematis Montana*, *C. Jackmanii*, *C. lanuginosa*, and many other varieties of that useful genus are well known on account of their profuse-flowering qualities, and we have seen them grow well and flower freely in exposed

positions, even as far north as Leeds. The common Hop plant is also one of our best coverers, and of Honeysuckles there are several species that flower freely. *Solanum jasminoides*, *Bignonia capreolata*, and *B. grandiflora* are likewise all suitable plants for sunny walls on warm soils, where they grow and flower freely; nor must we forget the different kinds of *Magnolia*—*M. grandiflora*, *M. purpurea*, *M. Soulangeana*, and *M. glauca* being the best. *M. grandiflora* and its variety, *exoniensis*, are very useful in warm situations, having glossy evergreen foliage and large fragrant white flowers.

Colonnade at Holland House (exterior view).

THE FLOWER GARDEN IN WINTER AND SPRING.

It is during the winter season that we appreciate flowers most, since many of our favourites are then rendered conspicuous by their absence; but it really

requires little trouble or outlay to obtain and keep up a stock of hardy winter and spring-flowering plants and bulbs. After the bedding plants are cleared away is the proper time to dig over the beds and see about planting dwarf evergreen shrubs, bulbs, and trailing plants, so as to hide the bare soil, even if nothing further is attained. If however, as frequently happens, this has not already been done, not a moment should now be lost in making up for loss of time. Those who have seen the beautiful effects obtained by the use of common spring-flowers at Belvoir or Cliveden, will best comprehend what can be done in this way by the judicious use of simple means. No time must now be lost in planting Tulips, Hyacinths, Crocus, and Anemones, the flowers of which do so much towards making the first bright days of spring enjoyable; while Hepaticas, Primulas, Arabis, Aubrietia, Forget-me-nots, variegated *Lamium purpureum*, *Stachys lanata*, *Cerastium*, and other plants equally hardy, will assist in producing an excellent effect. One of the finest of all spring or early summer-flowering plants is the pale blue *Myosotis dissitiflora*, which may be readily propagated in any quantity from seed, and it is simply invaluable for dry banks or beds, not only in the flower garden proper, but also in the

half-wild parts of the pleasure-grounds, where it can be associated with Primroses, Blue Bells, and other native plants. During the early part of the winter, say in November and December, Pompones and other Chrysanthemums are available for the decoration of flower-beds, more especially those nearest to the house. They can be readily propagated from cuttings in April, and may be grown on in pots outside all the summer, so as to be in readiness for removal to the flower garden as soon as the bedders are cleared off in the autumn. The centres of large beds are best filled in with groups of Conifers and evergreen shrubs massed together for effect, leaving margins round the side for spring-blooming plants and bulbs. The best shrubs for the purpose are Retinosporas and Thujas, green and variegated Hollies, and Aucubas. Ivies, and the gold and silver-variegated Periwinkles may be used with good results for edgings and borders. One of the best of all spring-blooming annuals is the *Saponaria calabrica*, the seeds of which should be sown in autumn, on dry banks or borders, and in such positions it will be found a charming companion plant to the blue *Myosotis dissitiflora*, before-mentioned, forming great breadths and patches of the most delicate rosy-lilac colour imaginable, and lasting in bloom for several successive weeks. Of the common Primrose, one of the finest of all spring-blooming plants, we have now many beautiful sorts, varying in colour from pale yellow, through all the shades of lilac and pale rose, to bright rich crimson; and these can scarcely be used too extensively in producing lively effects early in the year. They are easily propagated by dividing the clumps after flowering, when they should be planted in rows in some light deep earth, and well watered, especially during hot dry weather, when they are liable to suffer; for we must remember that naturally the Primrose is a moisture and shade-loving plant, and is too often neglected when the summer bedding-season commences. In partially neglected portions of the lawn or pleasure-grounds very pretty effects may be produced by planting yellow, white, or purple Crocus, Snowdrops, and yellow Daffodils. These peep through the herbage early in the spring, and produce a delightful effect, while the common yellow *Caltha palustris* is well worth naturalising on the margins of ponds, or in wet situations where other plants fail to grow. With the great wealth of material, both British and exotic, at our command, we may make our gardens as delightful in the spring as at any other time of the year, and even more interesting, since the number of distinct species we may employ is far greater and better suited for close examination than are those in general use for bedding purposes during the summer months.

F. W. B.

CARPETING BORDERS BENEATH SHRUBS.

In places where greenhouse plants are used (says the *Farmer*) to decorate the grounds, whether they are turned out or the pots are plunged, the appearance of the border devoted to them is greatly improved if the surface of the soil be covered with some low-growing and rapidly spreading plant. We have seen *Portulacas* sown broadcast with very good effect, but the trouble with these is, that the seed germinates slowly, and the plants do not make much show until late in the season. The best attempt we have seen at carpeting was where *Gnaphalium lanatum* was used. This bedding plant is propagated with ease, grows rapidly, and soon covers the soil with a carpet of a neutral grey tint, against which bright foliage and flowers show to the best possible advantage. This is a point in gardening that has received less attention than its importance demands. If the soil of beds in which plants are temporarily placed be carpeted with some rapidly growing plant of a pleasing colour, not only is the general effect heightened, but of course much labour in keeping is saved. In permanent shrubberies, too, this is a matter of no little importance. The soil beneath our shrubs is either bare or covered with weeds. Why not grow some pleasing plant which shall cover the ground and save all trouble of weeding? We are trying two plants for this purpose. In one row of shrubs we have set plants of Money-wort (*Lysimachia Nummularia*), which always grows rapidly enough when allowed to become a weed, and which makes as dense a mat as can be desired. In another clump of shrubs we are trying *Cerastium Biebersteini* (a variety of Mouse-Ear Chickweed). We have not had either of these long enough upon trial to be able to say more than that they promise well. The common Periwinkle (*Vinca*) would probably be useful in such places, and the Moss Pink (*Phlox*

subulata) might be tried. Could we get a set of low-growing plants that would flourish well beneath the drip of the shrubs, and completely cover the surface, it would not only greatly improve the appearance of our grounds, but do away with the necessity for weeding. When shrubs are set out to remain in one place for years, the soil should be so well prepared at the outset that there will be no need of the annual forking in of manure that many think it necessary to give their shrubberies every spring.

Wintering Alpine Plants in Pots.—The greatest enemy to Alpines in low-lying situations is excessive wet and damp. Accustomed as these miniature gems of the vegetable kingdom are in their native habitats to be frozen dry for nearly six months of the year, it is evident that what they require is not to be protected from cold, for no amount of frost will injure them, but to be sheltered from excessive rain and snow. Where there are large quantities of these plants to be preserved through the winter months, it is scarcely possible to place them all in frames under glass without going to a great expense; therefore, the following plan, which I have now tried for two years may be useful. I place a row of bricks or empty pots on the side of a north wall, and about 12 inches from it; on these I lay the plants with the crowns of foliage outward, in a horizontal position, tier upon tier, with a slight incline towards the wall, filling in between the pots and the wall with fine ashes or sand. It will, therefore, be seen at a glance that the rain falls on the sides of the uppermost row of pots, while the plants in them remain as dry as when they were first placed there. For some Alpines a south aspect is better than a north, especially such as have tomentose foliage.—R. P., York.

Propagation of *Scolopendrium vulgare*, var. *Wardii*.—Having been successful in propagating large quantities of this hardy Fern, which is one of the prettiest of the dwarf-crested and bulb-bearing varieties of the Hart's-tongue, I wish to record my experience for the benefit of your readers, as it very rarely, if ever, produces any fructification. My method of increasing it is as follows:—Procure some good established plants, place them in a warm pit near the glass, and let them remain there for three or four weeks. Then introduce them into the coolest end of the propagating house, still keeping them near the glass. Thus treated, in a short time they produce quantities of small bulbils on the edges of nearly every matured frond, and from these the stock may easily be increased. Prepare a small seed-pan or pot, and half fill it with finely-broken crocks, which cover with rough peat, and fill to within half an inch of the top of the pot with fine soil, consisting of two parts peat, one of well-rotted leaf-mould and another of loam, with a fine admixture of sand, and some finely broken potsherds, all well mixed and finely sifted. Distribute the small bulbils carefully over the surface of the soil in the pans thus prepared; water rather sparingly, cover with a square of glass, and place them in a cool part of the propagating-house case. Under ordinary circumstances, they will be ready in three months for transplanting into store pots, prepared as the pans were, and as they make progress in growth they may be potted and gradually hardened off, until eventually they are planted in a moist nook in the outdoor Fernery or rock-work, or even in a greenhouse, where they are seen to better advantage.—S.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Culture of the Double Primroses.—I have repeatedly failed to grow these well and increase them rapidly, and shall be greatly obliged if any correspondent of THE GARDEN will kindly tell me what is most essential to success with these lovely hardy plants.—J. N. H.

Crimson Chilian Beet.—This forms a beautiful indoor decorative plant if potted and removed to a warm greenhouse in autumn. It soon establishes itself and throws out its fine glossy crimson-veined foliage in great quantities, the colour being very bright and effective mingled with fresh green Ferns, Palms, and other fine-foliaged plants. Grown in pots it is very useful for conservatory decoration during the winter season.—Q.

***Adiantum Hendersonii*.**—I consider this to be one of the most useful of all the *Adiantums*, more especially for table decoration. Its young fronds are of a bright purple tint, and contrast well with those more fully developed, while the whole plant has a graceful appearance, its fronds drooping on all sides very elegantly. It will be found to be invaluable in pots for decorative purposes or for cutting, and it grows well in but a moderate temperature.—A.

***Viola White Swan*.**—In my notice respecting this new bedding *Viola* in a previous number of THE GARDEN, I omitted to mention that it is an exceedingly early bloomer. As it was a seedling of the previous summer, of course that point in its character had not been tested, but now that we are passing through the chill season, it is gratifying to find that this *Viola* proves itself to be the very earliest variety in cultivation, every shoot of it being now in bloom, whilst not a bud is visible on any other *Viola* or Pansy. If this earliness to flower should prove to be of a permanent character, I am disposed to believe that this white-flowering *Viola* will become a most useful plant to grow for the supply of white blooms during the winter months.—A. D.

THE ARBORETUM.

ORNAMENTAL EVERGREEN BERBERRIES.

SOME of these come to us from the west, some from the east. America has contributed a large number, and has an abundance of others in store to reward the enterprising collector. Nor does the warmer part of Asia yield the palm in this respect. The evergreen Berberries should be divided into three principal groups, viz:—I. Those in which the leaves are simple, and the flowers solitary, or fasciated in the axils of the leaves.—II. Those in which the leaves are simple and the flowers in lengthened racemes or panicles.—III. Those in which the leaves are pinnated. In this order they are treated of here.

Leaves simple, Flowers solitary, or, if in Clusters, one only on a Stalk; the Stalks all springing from the Axils of the Leaves.

Crowberry-leaved (*B. empetrifolia*).—From the country lying between the Straits of Magellan and the Cordillera near Valparaiso. A little trailing bush, with stiff three-parted spines, and linear pungent leaves, not unlike those of *Genista anglica*, bright green, clustered, and about an inch long. From their axils appear, in the month of May, a few bright yellow flowers, growing singly or in pairs, on stalks shorter than the leaves. This is a well-known plant, suited for rock-work in a mild climate, but among the less valuable of the genus.

Box-leaved (*B. buxifolia*).—A very common plant all over the southern regions of South America, throughout Patagonia, Chiloe, Tierra del Fuego, and the Straits of Magellan. In gardens it forms a straggling bush, with small ovate, or oblong, spiny-pointed, toothless leaves, of a dull dark-green above, and somewhat glaucous with indistinct veins beneath. When the bush is old, it produces an abundance of strong three-parted spines, which are longer than the leaves, some of which are toothed, and obovate instead of ovate. The flowers grow singly or in clusters, are very deep yellow, and rather larger than usual in the genus. It is almost universally known in gardens by the erroneous name of *B. dulcis*; but I have it from Messrs. Veitch under its correct designation, they having raised it direct from seeds collected by Mr. T. Lobb. In its early state, the leaves are much rounder than in the more advanced stage. In "*Flora Antarctica*," is the following account of the wild plant:—"This is a variable species, especially in the foliage, exhibiting a different aspect at different seasons of the year. In spring, when the flowering commences, fascicles of new leaves are produced, which are pale green, membranous, and entire. At this period the leaves of the former season begin falling, while those of the present year gradually become larger, stiffer, coriaceous, and generally mucronate or pungent at the apex. They are not fully developed till autumn, when they are generally quite entire, attenuated at the base, and shortly petiolate, about half an inch long, rigid and coriaceous, reticulated on the upper surface; during the following spring these in their turn fall away. In seedling plants the leaves are larger than at any future time, on long petioles, broader, and here and there furnished with spinous teeth. The flowers are pale yellow, generally in threes, but sometimes solitary. The berries, about the size of a small Pea, were much used for tarts by the officers of the *Beagle* and found excellent. The *B. dulcis*, of Sweet, agrees with the common form of this plant, except that the flowers are larger in that author's figure, and the pubescence of the pedicels not visible in the wild specimens. The *B. inermis* seems a variety, some of the specimens being quite unarmed: indeed, the spines of this genus afford but an inconstant character." For the purposes of cultivators it may be desirable to distinguish the true *B. buxifolia* from the Straits of Magellan, from the *B. dulcis* from Valdivia. The latter has larger and more spathu-

late leaves, larger fruit, and is more deciduous. The former is also a dwarfer plant. They are not, however, specifically distinct.

Yellow (*B. lutea*).—A native of the mountains near Veto in Peru, at the height of 12,000 feet above the sea. Ruiz and Pavon say that it grows in coldish places (*locis frigidiusculis*). In its wild stations this is said to be an evergreen bush as much as 18 feet high; it has, however, all the appearance of being much smaller. The branches are downy, and thickly covered with small leaves the size and colour of *B. Darwinii*, oblong, with three or more spiny teeth when young, perfectly undivided, narrower, and mucronate in old plants. The spines are small and slightly three-parted. The flowers grow in fascicles from among the leaves, on slightly downy foot-stalks. It has stood out during two winters with Messrs. Veitch. It is a very pretty little species, and, if hardy, will almost rank with *B. Darwinii*, from which it differs in its flowers not being in racemes.

Wallich's (*B. Wallichiana*).—An evergreen of most beautiful aspect, with brown branches, a very dark green dense foliage, and long, slender, three-parted spines. The leaves grow in clusters, are about 3 or 4 inches long, with a sharp prickly point, and numerous fine serratures, ending in a straight point on each side; on the upper side they are a rich bright green, turning to a claret colour in the autumn, and remarkably netted; on the under side they are pale green and shining. Wallich describes the flowers as growing

on foot-stalks, clustered in a round dense fascicle, and pale yellow. As it is a Java plant, it may be the *B. xanthoxylon* mentioned, but not described, in Hasskarl's "*Hortus Bogoriensis*." If so, that name must give way to Dr. Wallich's.

Leaves simple. Flowers in Racemes or Panicles.

Ilex-leaved (*B. ilicifolia*).—Wild in Tierra del Fuego and about the Straits of Magellan. This very rare shrub is described as being a straggling bush about 8 feet high, and the handsomest species of the genus. It has bright glossy Holly-leaved foliage, large clusters of fine orange-coloured flowers, and berries of a deep steel blue tint. The leaves are described as being obovate, petiolate, acute, coriaceous, dark shining green, especially above, pale beneath; the margin coarsely and distantly serrated, and each serrature armed with a distinct spur. The plant which flowered

Colonnade at Holland House (interior view, see p. 29).

at Kew is unfortunately dead, and the species requires to be re-introduced. There is not a more ornamental hardy shrub in any of our foreign possessions.

Darwin's (*B. Darwinii*).—Chiloe and Patagonia. An evergreen shrub 3 to 5 feet high, of extraordinary beauty, and conspicuous for its ferruginous shoots, by which it is at once recognised. The leaves of the deepest green, shining as if polished, not more than $\frac{3}{4}$ inch long, pale green, with the principal veins conspicuous on the under side, with three large spiny teeth at the end, and about one or two more on each side near the middle. Although small, the leaves are placed so near together that the branches themselves are concealed. The flowers are in erect racemes, and of the same deep orange-yellow as in the Box-leaved species.

Small-flowered (*B. parviflora*).—Supposed to be a native of South America. It is a pale-wooded evergreen bush, with slender branches, small, rather fine spines, and bright green leaves, without a trace of glaucousness. The leaves are about $1\frac{1}{2}$ inches long by $\frac{1}{2}$ an inch wide, and have pretty exactly the form of a lengthened wedge, whose upper end is almost always divided into three nearly equal coarse spiny teeth; other teeth, however, occasionally appear at the sides. The flowers are unusually small, and grow five or six together in nodding clusters, whose stalks are nearly as long as the leaves. Among all the evergreen species this is known at first sight by the form of its leaves. Perhaps its nearest relation is *B. Lycium*. It differs from *B. virgata*, whose name it sometimes bears, in the form

of its leaves, and especially in the flowers being racemose, not solitary. It is a true evergreen, perfectly hardy, and rather handsome.

Loxa (*B. loxensis*).—If it were not for its smaller size and much more diminutive flowers, this would be regarded as a variety of *B. Jamiesoni*. It has small palmated spines, and very shining, blunt, obovate, bright green leaves, of nearly the same colour on both sides; they seem to have in all cases a spiny point, and very often several teeth at the sides. The flowers are unusually small, and stand erect in paniced racemes on a long peduncle quite clear of the leaves. Its hardiness is uncertain; but its beautiful foliage makes it worth some protection if necessary.

Wavy (*B. undulata*).—From the mountains of Peru. This has slender branches, and weak palmated spines. The leaves are dull green, scarcely glaucous, oblong, tapering to the base, remarkably wavy, and furnished with a few spiny distant teeth, without any distinct trace of netted veins. In a wild state it is a stout stiff bush, with three-parted or five-parted spines, sometimes as much as $1\frac{1}{4}$ inches long. The leaves are thick, narrower than in the cultivated plant, but still preserve their undulated appearance. The flowers appear in small roundish, nearly sessile racemes, which are scarcely so long as the leaves. In this state it is not unlike the figure of *B. flexuosa* in the "Flora Peruviana," but the spines are not corky at the base, the racemes are much shorter, the flowers smaller, and the leaves thicker. It is a hardy evergreen shrub, from 4 to 6 feet high.

Orange-flowered (*B. aurahuacensis*).—Found in the province of New Granada, near the village of Aurahuaco-Taquina, in the Sierra Nevada, or Snowy Mountains, at about 9,000 feet above the sea, near the snow-line. It is an elegant shrub, with straight erect branches, and to be distinguished by bearing leaves of two sorts: the lower cordate, slightly enlarged and angular in the sinus where they are jointed by the petiole, which is very long; the upper obovate, elliptical, tapering to the base, coriaceous, wavy, with a few marginal spiny teeth near the end, very glaucous beneath. The flowers are in compact racemes, drooping, and very deep yellow.

Jamieson's (*B. Jamiesoni*).—This very beautiful Peruvian bush has leaves of the deepest green and most lucid surface; they appear in fascicles, and are nearly 3 inches long when full grown; in form they are oblong, a little narrowed at the base, with a spiny point, and a few spiny toothings on each side, or with scarcely any; beneath they are pale green without a trace of glaucousness. The flowers are in close, somewhat erect, paniced racemes, about 3 inches long. This must certainly be a plant of great value in gardens. Not so hardy as Wallich's Berberry.

Whitened (*B. dealbata*).—From the mountains of New Granada. A good-looking shrub, with stout brown branches, scarcely spiny, and undulated leaves of a bluish-green on the upper side, and almost white beneath. The latter are generally truncate, with three spiny teeth at the end, and two or three more at the sides, sometimes 2 inches long, and $1\frac{1}{4}$ wide. In the "Botanical Register" they are not well represented, being much too small, and not distinctly enough truncate. The flowers appear in April, in short, oblong, very compact drooping yellow racemes.

White-backed (*B. hypoleuca*).—One of the stoutest of the genus, with strong, very pale, erect branches. The spines are unusually small for the size of the shrub. The leaves are larger than in any other simple-leaved species, sometimes measuring 4 inches in length by 2 in breadth; they are leathery, strongly netted, dull dark green, and very white underneath; at the edge they are furnished with coarse rather spiny teeth. The flowers are about the size of those of *B. vulgaris*, and appear sparingly in long-stalked corymbs. It is a remarkably fine species, likely to rival the Kushmul in stature. It is truly evergreen, but is sometimes slightly injured in the foliage by a severe winter.

Kushmul (*B. asiatica*).—Found in all the mountainous country north of Hindostan, where it appears to be called Kushmul. It is correctly distinguished from the Chitra, or *B. aristata*, by Dr. Royle. This is the largest of the species in cultivation, growing quickly to the height of 8 or 10 feet, with pale erect branches, rather small spines, and a beautiful lucid, bright green, glaucous foliage. The leaves are oblong, tapering to the base, and a good deal netted when old; as in all the Indian species, they are toothed in various degrees, according to age or other circumstances; when toothed they are invariably scalloped, as it were, and not serrated as in the Chitra. The flowers grow in very short, roundish, sessile racemes, scarcely projecting beyond the leaves, and are succeeded by clusters of dark purple roundish berries, covered with a rich bloom like a Plum. In India these are dried and sold as raisins, which they much resemble, except in size. It is the best known of all the Indian Berberries, having been longest in cultivation, and in the south-west of England has become extremely common. Thousands of plants have been distributed by the Horticultural Society. Nowhere, however, has it

been cultivated, with so much success, or on so large a scale, as at Killerton, the seat of Sir Thomas Dyke Acland, Bart., from whose gardener I have received the following account:—"About eighteen years ago I received a packet of seed of *Berberis asiatica*, from which I raised about 100 plants. After keeping them two or three years in the nursery, I planted them out singly in different situations both at Killerton and Holmcote. The plants grew vigorously, were allowed to make their natural growth, and in a few years, at the latter place, began to seed. Being near the sea, the late spring frosts did not kill the blossoms; and from those plants we have now, for several years, obtained many pounds of seed, the plants being upwards of 14 feet high, and as many in diameter. From the commencement of their ripening with us, the seeds have been sown annually in drills, or broadcast in beds in the open ground, about the first week in March, in a light soil, letting them remain in the above situation until the spring after. I then plant them out in the nursery in rows, about 15 inches from row to row, and about 6 inches from plant to plant. In two years they make fine strong bushes for permanent situations. Finding the plants to be free growers, nearly evergreen, and very strong, and raising many thousands per year, I began, by the desire of my employer, to plant them out for hedges, and they succeed particularly well, either planted on banks or on the bare surface. The latter I can highly recommend for dividing allotments in cottage gardens, this Berberry being free from mildew; and it can be kept clipped with shears or shorn with a reap-hook to any width required. When planted on a bank, it makes a beautiful hedge by cutting out with a knife the very luxuriant shoots about twice a year to within an inch or two from where they grow, allowing the side and weak growth to form the hedge. I have a hedge at Killerton so treated, which has been planted upwards of twelve years, and at this time is not more than 4 feet high and about the same width; and with the same treatment it can be kept to the same size. I should recommend, in planting hedges, to keep the plants a foot apart, and, if the hedges are to be kept shorn, in a single row; but if to be kept in the more natural growth, plant two rows, not more than 1 foot apart, and the plants the same, but put in alternately. When strong, this Berberry is proof against any cattle. Last spring I planted a stout bush in the deer park without protection. They have rattled it with their horns, but they have not killed it. It can be planted nearer a fence where cattle have access than any shrub I know." It is, indeed, a most valuable plant, and hardy enough to defy the rigour of any frosts south of the Humber. Many varieties are to be found in gardens, but they are not different in important characters.

Chitra (*B. aristata*).—Long known as a Nepal plant, and more particularly described by Dr. Royle as inhabiting the Himalayas at from 5,000 to 8,000 feet of elevation, from Jurreepanee to Mussooree, and on the Choor Mountain: its hill name is Chitra. It is also found on Nuera Ellia, in Ceylon, and probably grows along the whole of the Neilgherry range. By no means uncommon in gardens, where it forms a stout evergreen bush, with dark brownish-red spreading branches, and shining rich green leaves, usually fringed with bristle-pointed, fine, close serratures, whence its specific name. The flowers are large, bright, not dark, yellow, in loose, paniced, long-stalked racemes hanging down beyond the leaves. They are succeeded by an abundance of red, bloomless, oblong, acid berries, which hang on the branches till Christmas. The fine, close, bristle-pointed serratures of the leaves, the rich reddish-brown branches, and the long, loose, paniced racemes of flowers are quite peculiar to this plant, and separate it clearly from every other. Dr. Royle tells us that its fruitforms a part of the hill "raisins" of Nepal; in England they acquire no bloom, and would not readily dry. Like *B. asiatica*, this produces several varieties, one of which I propose to call the "entire-leaved Chitra" (*B. aristata integrifolia*). It is distinguished by the edges of the leaves being almost wholly destitute of bristles, and is known in some gardens under the false name of *B. Wallichiana*, to which it bears no resemblance. The plant figured in the "Exotic Flora" has the leaves of *B. petiolaris* of Wallich, a species which I have not myself seen alive; at least their toothed, not serrated, margin would lead to such a conjecture; at the same time the flowers are exactly like those of *B. aristata*.

Umbelled (*B. umbellata*).—Dr. Wallich's collectors appear to have first discovered this plant in Kamaon and Gossain Than. For its introduction to our gardens we are indebted to the East India Company. It is a hardy bush, about 4 feet high, with a spreading manner of growth, pale brown, angular branches, slender three-parted spines, and very narrow, bluish-green leaves, strikingly glaucous beneath; on an average they are $1\frac{1}{4}$ inches long by $\frac{3}{8}$ wide; sometimes they are perfectly entire, in which state they are represented in the "Botanical Register"; but they are more commonly furnished with a strong, marginal, spiny tooth or two, and sometimes with many. (Can this state be the *B. ceratophylla*?)

of G. Don?) The flowers are pale yellow, in drooping, narrow racemes, and are succeeded by an abundance of oblong purplish fruits. The species is very pretty, in consequence of its graceful manner of growth. It is best suited for growing among rough places, such as heaps of rock-work, where its spreading way of branching can best be seen. It is not, however, a good evergreen, the leaves being too thin and pallid.

Dyer's (*B. tinctoria*).—Found wild in the Neilgherry Mountains, whence it was lately introduced by the East India Company. The plants in gardens are slender brown-wooded shrubs, with small slender spines, usually three-parted. The leaves are thin, not shining, dull green above, glaucous beneath, oblong, blunt, with a spiny point, but scarcely spiny-toothed, except on the seedling plant. The flowers have not hitherto appeared. They are represented by Dr. Wight as standing erect in loose racemes scarcely longer than the leaves, and succeeded by an abundance of dull red fruit. In the absence of such evidence there would be some doubt as to this; for botanists have evidently misunderstood the distinctions of some of the Indian Berberries. M. Delessert, for instance, figures a *B. tinctoria*, declaring at the same time that it is nothing but *B. asiatica*; yet *B. asiatica* has no resemblance to the plant now described, whose leaves are glaucous, not bright green, thin, not coriaceous, almost veinless, not strongly netted. Dr. Wallich, on the other hand, distributed, under the name of *B. tinctoria*, specimens which in part at least belong to *B. aristata*. But the specimen from Leschenault in Wallich's Herbarium, deposited with the Linnean Society, is extremely glaucous beneath, and appears to agree with the garden plant, as it does with Dr. Wight's figure. It appears to be only a sub-evergreen, and to be tolerably hardy. Its name has been given it in consequence of its furnishing, like other species, a fine yellow dye. Vauquelin states that it is inferior to few woods for that purpose.

Ophthalmic (*B. Lycium*).—According to Dr.

Royle, this occurs in the Himalayas from Rajpore to Mussooree, at an elevation of from 3,000 to 7,000 feet; also from Nahn to Choor. This bush derives its name from having been discovered by Dr. Royle to be the real *Lycium indicum* of the Greek physicians. To this day its extract is used against ophthalmia with great success, as in the time of Dioscorides. Its branches are erect, pale brown, and angular, armed with three-parted spines of unusual length for the size of the leaves. The latter, when young, are glaucous on the under-side; but in winter they are nearly green, and become a dull, unpleasant, brownish-red. In form they are oblong-lanceolate, spiny-pointed, with several lateral spiny teeth; sometimes, however, they are toothless. The flowers grow in long, erect, somewhat paniced racemes, much longer than the leaves. This is a bad evergreen, but a pretty summer bush. It is perfectly hardy.

Leaves Pinnated, or Trifoliate. Ash-leaved Berberries or Mahonias.

Three-leaved (*B. trifoliata*).—In the North of Mexico, among stunted Mimosa and Cacti, this plant is found occupying large tracts of country. It is a charming evergreen bush, with prickly, deeply scalloped leaves, having bluish-green variegated leaflets, in threes, sessile at the end of a stalk either longer or shorter than themselves. On the under side they are quite glaucous. The wood is hard, reddish-brown, and somewhat streaky. The flowers are pale clear yellow, growing from three to five together, in small nearly sessile racemes, in the axils of the leaves. The fruit has not been yet

formed in this country; it is said to be eaten by the children that inhabit its native wildernesses. It grows 3 or 4 feet high, and has hitherto proved hardy near London.

Thin-leaved (*B. tenuifolia*).—A Mexican shrub, from the foot of Orizaba. No probability exists of this graceful plant being hardy, it being destroyed by only a few degrees of frost. It is easily distinguished by the leaflets of its long pinnated leaves being ovate-lanceolate, pale bright green, and perfectly free from all trace of toothing. Its flowers appear in abundance in long, simple, erect, loose, open racemes, opening, in the month of December, in a greenhouse. It is said to grow 10 feet high in its native places, and is a good conservatory plant.

Pallid (*B. pallida*).—An evergreen shrub, from 5 to 6 feet high, from the mountains of Mexico. A handsome species, with pinnated slightly prickly leaves, and long paniced racemes of pale yellow flowers, succeeded by globular, dark purple, glaucous fruit, the taste of which is not only unpleasant, but particularly acrid. It makes a fine greenhouse shrub, but is too tender for the neighbourhood of London.

Prickly (*B. fascicularis*).—A species confined apparently to the lowlands of California and the north of Mexico. With much the appearance of the Holly-leaved Berberry, this is, I apprehend, a distinct species; when alive, distinguishable by its much more prickly leaves, and their want of lucidity, especially on the under side, which is as unpolished as in the Creeping Berberry. It is also more

arborescent; its inflorescence is much more compact, and it is far more impatient of cold, not living in the open air near London, except under the shelter of a roofed wall. A hybrid, between it and *B. Aquifolium*, exists in cultivation, said to have been raised by Mr. Rivers. It is of a larger growth than the prickly Berberry, and has its compact inflorescence and dull hard leaves, but all the habit of the Holly-leaved. This *Berberis hybrida* is a good-looking evergreen, and perfectly hardy.

Berberis nepalensis.

Nepal Ash-leaved (*B. nepalensis*).—A native of the mountains of Northern India, extending as far to the eastward as the Munipoor country, according to Roxburgh. It has, as will be seen by the accompanying illustration, pinnated leaves a foot and more in length, with five or six pairs of sessile, ovate, oblong, obliquely cordate, coarsely spiny-toothed leaflets, the largest of which are 3 inches long and 1 inch broad. From among them rise erect, simple racemes of large flowers, sometimes as much as 6 inches long. The fruit is oblong and dark purple. The leaves of the seedlings are glaucous on the under side. It was raised at Chiswick from seeds supplied by the East India Company.

Holly-leaved (*B. Aquifolium*).—All over the north-western parts of North America, both in the Hudson Bay Company's territory and in Oregon, this plant is found in woods. It does not appear to inhabit California. Than this we have no finer evergreen in cultivation. Hardy enough to bear all winters, putting forth its half-transparent rosy foliage in the spring, hardening it into a gloss and texture not inferior to those of the common Holly, and bearing in the autumn enormous quantities of large globular deep purple berries, covered with a bloom that rivals that of the finest raisins, this shrub is certainly one of the most valuable of the numerous species for the introduction of which Europe is indebted to the Royal Horticultural Society. It thrives in sandy or clayey land, in wet places, or on precipices, overshadowed by trees, or exposed unsheltered to the sun. In the latter situation it bears fruit most abundantly, and therefore may be ranked as the first among bushes

suitable for rock-work. This character applies however, strictly, only to the true Holly-leaved Berberry, the leaves of which are a bright clear green, very shining, even on the under side, and a rich vinous red along the leaf-stalks. In the nurseries are numerous varieties of inferior merit, with broader leaves, not shining on either side, of a duller green, and apparently hybrid varieties between this and the Creeping Berberry (*B. repens*). They, too, are fine evergreens, but not so handsome as the genuine original kind. It is desirable that they should be separated by the nurserymen who deal in them.

Creeping (*B. repens*).—A native of North-West America, according to United States nurserymen, by whom it was first sent to Europe. I suspect, however, that it is confined to the Rocky Mountains, for it is not among Douglas's plants, and it has lately been met with on the mountains of New Mexico by Mr. Fendler, by whom it has been distributed under the name of *B. Aquifolium*. It is the opinion of many botanists both in Europe and the United States, that this is a mere variety of the Holly-leaved Berberry. I cannot agree with them, unless they use the word species in the same sense as those who identify the dog with the wolf and jackal. The Creeping Berberry owes its name to its great tendency to form what are called creeping roots, for which it is much more remarkable than the Holly-leaved. It is a dwarf bush of no great beauty, scarcely exceeding a foot in height; its leaflets are not shining, are not sharp-pointed, are little prickly, but are roundish, of a dull glaucous green, and few in number. Moreover, it has few of the good qualities which distinguish the other. It is, however, to be observed that it breeds freely with the Holly-leaved, and from this mixed parentage has probably arisen the spurious form of the Holly-leaved to which I have alluded in mentioning that species. It can scarcely be said to be worth cultivating except in botanical gardens.

Chaffy-stemmed (*C. glumacea*).—Found in shady Pine woods at the mouth of the Columbia, N.W. America, where it is common. This well-known plant forms a close bush, about a foot high, and produces every year an abundance of upright racemes of pale yellow flowers, succeeded by globular purple berries, covered by a fine bloom. Their taste is austere and acid. The species derives its name from its stem being covered by the long persistent lanceolate scales of the leaf-buds, which continue to clothe the stem like coarse chaff for many years. (Something of the same kind occurs in Fortune's Chinese Berberry). The leaves are nearly 18 inches long, and bear about six pairs of sessile leaflets, quite similar in form to those of *B. nepalensis*, pale green on both sides, lucid on the under, with a reddish petiole. In the "Botanical Register" it is remarked that, although perfectly hardy, this little plant cannot bear that the extremities of its shoots should be removed. It seems to have little power of developing new axillary buds if the terminal one is destroyed; so that, if injured, it either dies outright or remains in a stunted state.

Acanthus-leaved (*B. Leschenaultii*).—Dr. Wight says that this is found in almost every clump of jungle about Ootacamund, in the Neilgherries, flowering during the S.W. monsoon and at other seasons; the fruit, which is bluish-purple, ripening in the dry season. As far as we know anything of this, it must be a still nobler plant than *B. nepalensis*, its leaves being almost 18 inches long, with eleven or twelve pairs of leaflets, which seem to be harder and shorter, and much more closely set upon the petiole, than in *B. nepalensis*; the fruit, too, is globular, not oblong.

Japanese (*B. japonica*).—The earliest account of this is to be found in Thunberg's "Flora Japonica," where it is mentioned under the name of *Ilex japonica*, that traveller having mistaken a leaf for a branch, and the leaflets for true leaves. He found it cultivated under the name of Sassa Nanting, in Nippon, where he observed it while on his journey to the Court of Japan. Dr. Robert Brown afterwards, in 1818, pointed out this strange blunder, which indeed was sufficiently evident from the figure of the so called *Ilex* published by Thunberg himself in the year 1802. Mr. Fortune states that it grows from 100 to 150 miles N. of Shanghai, and that it is the most gigantic of the Berberries. The leaves are of a stout leathery texture, large and handsome.—*Horticultural Society's Journal*. [Can any of our readers tell us how many other species of this fine family are in our gardens at the present time?]

TREE GROWTH IN SOUTH AUSTRALIA.

PERHAPS it may interest some of your readers, as illustrative of the rapid growth of some trees here, if I state that a *Cupressus macrocarpa* planted eleven years ago is now 33 feet through, and the same in height. This is considered the finest specimen here, but as it is growing in sandy soil, I presume it will not live very long. This, of

course, is the Lambertiana variety, as distinguished from trees raised from seed, which are far less spreading in their habit. In *Sequoia gigantea* you undoubtedly beat us. I have one planted eight years since, that now measures 12 feet through, the branches reposing beautifully all round on the Grass, and is 21 feet high; the girth of stem, 1 foot from the ground, is 42 inches. This beautifully symmetrical tree is growing in sandy ground only 2 feet deep, overlying a 6-inch bed of gravel, under which is a compact bed of clay, rather sandy than otherwise. I was surprised a few months ago to find that its roots had not apparently penetrated the layer of gravel in the bed of clay below, for, on transplanting an *Araucaria excelsa* that was becoming too near to it, no roots of either appeared even in the gravel; indeed, we had some difficulty in transplanting the *Araucaria* owing to the gravel dropping away from under the ball during the excavation, being upheld by no roots whatever. However, the transplanting was successfully performed, and the tree is now in perfect health, four months having since elapsed. But for its perfect symmetry I would not have ventured on so heavy a work, for which, however, I am now well repaid. This tree is not so very large, having been planted at the same time as the *Wellingtonia*, but I have seldom seen one so perfectly symmetrical. It measures through its lower tier of branches just 18 feet, and is 21 feet 6 inches high. There are many much larger trees here, but the extension of the lower branches is generally interfered with by small subjects being planted near the trees when young. I may, perhaps, add that I have never seen an *A. imbricata* here with branches apparently so intricate and crowded as the one figured at p. 398 Vol. III. of THE GARDEN; it must be a truly magnificent specimen, ours here are much more bare, each branch and branchlet standing out clearly and distinctly. *A. Cunninghamii*, as it grows here, is more like it. My garden just now is almost too strongly redolent of the odour from Orange blossoms. My oldest plants are now about eight years old, and have borne fine fruit for years; some of the trees are 11 feet through, and about the same in height. I allow the lower branches to lie almost on the ground, in preference to forming a clear stem such as you see in the Orange-boxes in France; the ground is thus kept cool above the roots, which I find always very near to the surface, but not so close as where a mulch is used.

JOSEPH SAYCE.

Caulfield, Melbourne, Victoria.

A Good Hedge Plant.—In a prize essay on the subject of hedges, a Canadian writer recommends the Honey Locust (*Gleditsia triacanthos*) as a hedge plant for northern localities. He is "convinced from experience and observation that for a hedge plant suitable to the requirements of a very cold country, there is none superior to the Honey Locust. The following are a few of its superior qualities:—1. That it will stand the severest winters of this latitude uninjured. 2. There is no hedge plant that will grow with us and make a hedge in so short a time. 3. When it once becomes a fence, it will, with little care, remain so; not like some plants, in which, when kept constantly pruned, the lower branches die out, and thus make an ineffectual hedge. Some may imagine it to be only the common Locust growing here as an ornamental tree. It belongs, in fact, to a family of plants which do not sprout, and upon which the borer never works. The red bud and Kentucky Coffee tree belong to the same order as the so-called Honey Locust. There is a Honey Locust hedge at Elizabethtown, New Jersey, over forty years old. It is one mile in length, and has always been tight and strong, and is at this time known to be the best hedge on the continent. The hedges of J. L. Budd, of Benton County, Iowa, some four miles in length, are also beautiful, symmetrical, and a perfect protection against all farm stock. I mention these two instances because the one is in the rich prairies of the West, and the other in the sterile soil of the East."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

A Fine Maiden-hair Tree.—In the Botanical Garden, at Pisa, Italy, is a *Ginkgo*, or Maiden-hair tree (*Salisburia adiantifolia*), which has attained the height of nearly 90 feet, and at 3 feet from the ground is 9 feet 7 inches in circumference. It was received from England and planted in 1789. It is a splendid tree, and very remarkable for the rich golden colour which the leaves assume before falling.

A New Beech Blight.—In Westphalia the Beech trees have been recently attacked, it is said, by a new form of blight, which commences on the bark, and finally covers it with a snow-white down, to the ultimate destruction of the tree. Under the microscope this blight is seen to consist of fine threads, among which there occurs a small insect, apparently an undescribed species. The threads, which are secreted by the insect, are of wax, which has a melting point of about 80 degrees, and the percentage composition of which is, carbon 81.39, hydrogen 13.53, and oxygen 5.03. Both as regards its composition and melting-point, this new wax is very near that of Chinese wax.

THE INDOOR GARDEN.

TREE-FERNS.

(Continued from p. 9.)

Cibotium.

This is a genus of Dicksoniæ, distinguished by its two-valved coriaceous involucre. The veins are forked and venules free, bearing dentiform reflexed sori, the receptacles being punctiform and terminal. The celebrated Tartarian Lamb, *C. glaucescens*, belongs to this genus, but, as its growth is decumbent and not arborescent, it will not be included in the present enumeration.

C. Schiedei.—A beautiful cool-house Fern. Stem from 10 to 15 feet high, though trunks of this size must be very old, judging from the very slow progress they make in this country. Its fronds are spreading and pendent, from 6 to 12 and 15 feet long, bipinnate, the pinnules being small and deeply pinnatifid, light pleasing green on the upper side, and glaucous below. The involucre containing the sori are situated near the margins, and resemble little boxes. Stipes and rachis, as well as the crown, densely furnished with long woolly hairs of a light chestnut colour. Native of Mexico.

C. regale.—Until within a few weeks, it had been questionable with me whether this plant is a true *Cibotium*. Having, however, now found it in a fertile state, I have no longer any doubts on the matter. *C. regale* is at once a magnificent and elegant species, its broad erect arching fronds, with its finely-divided rich green pinnules, rendering it extremely ornamental. The stipes, rachis, and crown are densely clothed with long silky cinnamon-coloured hairs, which add materially to their beauty. It seems to form a trunk far more quickly than the last-named species, and, like it, thrives well in a cool or intermediate Fernery. Native of Mexico.

C. spectabile.—This plant resembles the preceding, in a young state especially; but, with age, I apprehend it will become very distinct. It is a free-growing handsome Tree-Fern, differing from *C. regale* principally in the colour of the long hairs which clothe the crown of the plant and the base of the fronds, which, in this plant, are ashy-grey or slightly tawny. Both these plants are undescribed in English books, so far as I am aware, but both are well deserving a place in every Fern collection. Native of Mexico.

C. Menziesii.—The first living plant of this species that came to this country, came under my care, and, as the genus was always a favourite with me, and the species belonging to it very few, those who are enthusiastic in their love for plants will quite understand the pleasure it afforded me. It is erect in growth and, in all probability, forms a stout stem, although I cannot speak positively on this point, having never seen a trunk higher than a few inches; the fronds are bipinnate, and leathery in texture; pinnæ large and pinnatifid, the segments being broad and obtuse. The involucre are very large and of great substance, and situated at the base of the sinus. The fronds are dark green in colour, the stipes and crown of the plant being clothed with short dun-coloured woolly hairs. Native of the Sandwich Islands.

Hemitelia.

A magnificent family of slender-stemmed stove Ferns, characterised by their simple or pinnately-forked veins and free venules, the lower pair of which, becoming united, form costal areoles. The sori are medial, enclosed in a half-cup-shaped involucre. This genus has always been to me a very fascinating one, the broad fronds, ornamented with the regular lines of large sori, rendering the plants very ornamental and very tropical in appearance. They require stove heat, and delight in an atmosphere well charged with moisture. The soil should be peat and loam in the proportion of two parts of the former to one of the latter, to which should be added a good portion of sand.

H. speciosa.—This species makes a stem tolerably quickly, but I am uncertain what height it attains in its native country. The fronds are very large, erect, and spreading, and are destitute of spines; pinnæ, deep green, from 12 to 15 inches long, broad and slightly lobed at the edges. The numerous large sori are situated near the margin in this species, forming a conspicuous broad continuous band. Crown of plant and base of fronds furnished with large dark brown scales. Native of Brazil and Caraccas.

H. grandifolia.—Stem 6 feet or more high. The fronds are from 6 to 7 feet in length, pinnate; pinnæ large, about a foot long, and pinnatifid; colour, bright shining green. The crown is furnished with scales, and the base of the fronds are spiny. It is a very noble plant. Native of several of the West Indian Islands.

H. horrida.—A truly grand plant; stem, some 8 or 10 feet high, perhaps more; fronds from 6 to 10 feet long, broadly lanceolate in outline, bipinnate; pinnules pinnatifid, and from 12 to 18 inches long, bright green on the upper side, paler below, where they are also slightly tomentose. The sori form a conspicuous and beautiful

ornament; the base of the fronds is scaly, and armed with long stout spines. Native of the West India Islands.

H. obtusa.—Nearly allied to *H. grandifolia*, yet distinct as seen growing side by side. The fronds are large, pinnate; the pinnules being deeply pinnatifid, and deep green in colour. The under side is furnished with a few whitish scales which, however, soon fall off. The base of the fronds is also furnished with short spines, as is the case with nearly the whole of the species. The sori form a beautiful ornament to the under side of the fronds. Native of the West Indian Islands.

H. Karsteniana.—This species is somewhat rare in our collections, but it must be a superb plant when it has arrived at maturity. On young specimens the fronds are very long, pinnate, with pinnæ from 10 to 12 inches long, obtusely lobed and deep green in colour. Native of Venezuela.

H. spectabilis.—Like the preceding, this is at present rare in collections, and only to be met with in the form of comparatively young specimens, so that it is quite impossible to judge of the height it will attain. It is a grand stove Fern, producing broad pinnate fronds from 12 to 15 feet in length, or even longer. The pinnæ are from 10 to 15 inches long, upwards of 2 inches broad, deeply lobed, the lobes being obtuse; colour, bright light green. Native of Venezuela.

H. Imrayana.—As a species, this would appear to be allied to *H. horrida*, but it becomes a very distinct and handsome species with age. I have only seen it in a young state. There are other kinds in cultivation, bearing the names of *H. subincisa* and *H. Klotschii*, but as they have not grown sufficiently large to determine whether they are distinct from those already enumerated, further notice of them must be deferred.

Thyrsopteris.

One species only has been found for this genus, and that is a native of the island known so familiar to every one as the residence of Robinson Crusoe. The plant in question,

T. elegans, is characterised by its broad de-compound, thick leathery bright green fronds, the fertile portion of the fronds being much contracted so that they appear like large paniced racemes of sori, whilst the involucre are calyciform, and the sporangia when magnified are seen to be each furnished with a little stem. It is an extremely beautiful plant, and as rare as beautiful, being only found in the best collections. It thrives in moderate heat, but likes abundance of shade and moisture. Native of Juan Fernandez.

Schizocæna.

A genus, having generally all the appearance of *Cyathea*, and to which the few species it includes are usually assigned, or of which it forms a sub-genus, I have the impression, however, that for all ordinary purposes, the well-marked characters which these plants have, entitle them to generic distinction. They differ from the former genus in their more coriaceous texture, in the sori being situated on the middle of a vein, and not axillary, and by the cup-shaped involucre becoming divided into (usually) about six obtuse lobes. A few species only belong to this genus, only one, however, as far as I am aware, being yet introduced, and the first plant of which I had the peculiar satisfaction of nursing into life in this country.

S. sinuata.—This real gem forms a very slender erect stem, not thicker than an ordinary walking-stick, but I cannot say to what height it attains. Those which have come under my own observation have not exceeded 2½ feet; they are black with the persistent bases of the frond-stalks; the crown of fronds is very elegant, they are simple and entire, usually from 10 to 18 inches long, and seldom exceed an inch in breadth, lanceolate in outline, the margins being beautifully undulated; they are somewhat thin in texture, and bright shining green in colour. When fertile, the sori upon the underside add materially to its beauty. It requires an abundant supply of moisture to keep its beautiful fronds from curling up, whilst the soil should be very light and open. This species appears peculiar to the island of Ceylon. One or two fine species of this genus are known to exist in Malacca, and I have recently received a beautiful species from Queensland, which would appear to be related also, so that I hope *C. sinuata* will not long be the sole representative of the genus in cultivation. G.

WINTER-FLOWERING ORCHIDS.

I HAVE just returned from a visit to the Orchid-houses of Messrs. Backhouse & Son, of York, and seldom have I seen Orchids in better health or better vigour! Mr. Marshall, who has these houses more especially under his own eye, has treated his beautiful nurslings with all the care they so eminently require, adapting to them just the conditions of growth and development that their capricious nature seems to demand to coax them into bloom. My attention was directed by

Mr. Marshall to upwards of a score of these beautiful flowers. *Odonoglossum Rossii* was well in flower and very lovely. It is a native of Mexico. The petals are beautifully spotted and contrast most happily with the pure white lip. Fine spikes of *Oncidium cucullatum*, with its hood of sepals and crimson spotted lip, were very conspicuous. Its inflorescence is extremely graceful. It is a native of Ecuador. The delicious fragrance of *Zygopetalum Mackayi* made itself felt on entering the house it occupied. It is a lovely dappled Orchid, and in its nature appears to blend and harmonise colours apparently incongruous. The *Masdevallias*, *tovarensis* and *coccinea*, white and crimson, natives of New Granada, exhibit curiously-formed flowers. To these I would seek to draw attention, without attempting to arrange or class them in their several groups, but simply noticing them as they presented themselves before me, irrespective of the gradations of temperature to which they are subjected. The *Calanthes* make a grand display, and I knew not which most to admire, *C. vestita rubra* or its very interesting hybrid, *Veitchii*, with its spike of rosy flowers. The curious *Angræcum sesquipedale*, a native of Madagascar, was staged in the same house. The flowers are of a waxy-white, and delicately fragrant. As the specific name implies, the spur often exceeds a foot in length, the upper sepal being cornute reflected or deflected in the several species. But I must not omit to notice a curiously marked Orchid, *Mormodes Claveringii*; as its generic name implies, it represents the imaginary outlines of some Mormo of antiquity. *Odonoglossum Insleayi Leopardinum*, very happily named by Mr. James Backhouse, is a most lovely flower, though it lacks fragrance. The *Lælias* in the Mexican house, *autumnalis*, *anceps*, and *albida*, form a beautiful group that must attract attention. But time would fail me to tell of *Lycaste lanipes*, *Phalænopsis grandiflora*, *Saccolabium giganteum*, *Sophranitis grandiflora*, or *Mesospinidium vulcanicum*, a name that indicates its association with extinct volcanoes.

PETER INCHBALD.

Hovingham Lodge, near York.

Cultivation of Gesneras.—Although these beautiful winter-flowering plants are generally to be found in our stoves, they are seldom so well grown as they ought to be. I usually grow from six to seven dozen of them annually, for the decoration of the stove or conservatory from December until March. The varieties which I use are *Exoniensis*, *Cinnabarina superba*, *Zebrina*, and *Splendidissima*, but many others are equally well worth growing. In addition to its floral beauty, I may mention that *Exoniensis* is one of the prettiest of foliage plants. I shake the tubers out of their pots in May, and place them thickly in a mixture of peat and loam, with a good sprinkling of silver-sand. As soon as they have made two or three leaves, I pot them singly in 60-sized pots, and place them in a Cucumber-house, shifting them into larger pots as growth progresses, until I get them into 16-sized pots, that is if large plants are required; but nice plants for decorative purposes may be grown in 32-sized pots. Gesneras are very partial to shade, and under that of Cucumbers they grow very rapidly. In watering, they require care, for if watered excessively they soon die. I prefer keeping them rather dry than otherwise. Liquid-manure, largely diluted with water, assists them wonderfully. In their successive shifts, the compost which I prefer consists of peat, loam, a little cow-dung, and plenty of silver-sand to keep the soil open. This I use in a rough state, potting moderately firm, and draining well. After they have done flowering, I place them on a shelf in the stove to complete their growth, and then dry them off gradually. Under this treatment, plants may be grown from 1 to 2 feet in diameter, and they will produce flowers in profusion.—D. S. GILLETT, *Court Garden, Great Marlow.*

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Browallia demissa as a Winter Bloomer.—I have never seen this old-fashioned plant so attractive as at present in one of the warm houses in the Wellington Nurseries, where it has been full of its pretty blue flowers for some weeks past. It would seem to be most precious as a winter ornament, as, when flowered in summer among annuals and similar plants, it is not so conspicuous or so useful. Seed of this sown in May, and grown rapidly on in a spent dung-bed, and the strongest shoots taken off for cuttings, will flower beautifully through the months of November, December, and January.—R. H. B.

Cœlogyne cristata.—Mr. Tanton (see p. 10) is correct in stating that *Cœlogyne cristata* is one of our best winter-flowering Orchids, but he is wrong in describing it as coming from Guatemala. It is a native of Nepal; and the best of some thirty known species of *Cœlogyne*, all natives of the eastern hemisphere. Mr. Tanton tells us that he has two plants, one with 160, the other with 230, bulbs, each bearing a spike of flowers. The plant only flowers from the young bulb, which will not stand in greater proportion than one in five, so if he has fifty spikes carrying from five to seven flowers on his largest plant it is extremely good; but his statement, that he has got a spike on every bulb, is scarcely credible. Such statements as these are not worth notice were it not for the mischief they are likely to do in rendering people, who possess similar plants, but who are deficient in knowledge respecting them, dissatisfied with their own.—T. BAINES.

THE FLOATING GARDENS OF MEXICO.

WHEN the city of Mexico was taken by the Spaniards under Cortez in 1521, it occupied several islands in the lake Tetzcuco. The water, from various influences, chiefly volcanic, has since receded, and the city, although still retaining its ancient site, is now $2\frac{1}{2}$ miles distant from the lake. At the time of the Spanish conquest, however, it presented very much the appearance of Venice, a "city in the sea," "throned on her hundred isles," the margins of whose broad and narrow canal-streets were in many places lined with splendid mansions. According to the ancient Spanish historians, the native Mexicans had at that time attained a high degree of perfection in various arts, for which they do not appear to have been in any way indebted to the civilisation of the Old World, and which must have been an out-growth of unaided indigenous talent. Among the many novelties and wonders which met the eyes of the Spaniards, were the *chinampas*, or floating gardens, which abounded on the lake, and supplied the city with vegetables, fruits, and flowers, the latter being in great request amongst the Mexicans for decorating the altars of their gods. These gardens were formed by constructing a large raft from the reeds and other aquatic plants which grew by the shores of the lake, making it sufficiently firm and buoyant to sustain a quantity of soil which was spread over the surface, and kept in position by a low fence of wicker-work, or intertwined reeds and branches, which ran round the edge of the raft. The fertility of these little floating islands, owing to the constant supply of moisture, is very remarkable, and the old chroniclers describe them as being literally covered with flowers and fruit and verdure. The city of Mexico is still, to a great extent, supplied from these singular market-gardens, which form the sole support of some villages on the shores of the lake, inhabited by families of the descendants of the aboriginal race who fell beneath the treachery of the sanguinary Cortez. Two of these villages, Santa Anita and Ixtacalco, which are not very far from Mexico, are particularly noted for the production of beautiful flowers, and, at certain seasons, when their floating gardens are in full bloom, they are a favourite resort of pleasure-parties of the citizens. Our illustration affords an excellent idea of the structure and general appearance of these interesting horticultural contrivances, the sole heritage of the outraged people who once possessed the splendid city, the view of whose domes and spires, still proudly rising from the distant horizon on the other side of the lake, must often awaken in many a toiling breast sad memories of long-departed greatness.

W. M.

PLANT FLY-TRAPS.

Now that the Sundew and the remarkable phenomena connected with it have been once more brought prominently before the public at the recent meeting of the British Association, and it has been announced on good authority that Mr. Darwin has been making observations upon the same subject for future publication, it may be interesting to give a brief *résumé* of the phenomena of a more or less kindred character which are manifested by certain other plants. It will be found that, besides the species generally reckoned as fly-traps, there are others, widely separated in their affinities as in their geographical distribution, which manifest similar peculiarities in a remarkable degree. The confirmation by Mr. A. W. Bennett of the observations of former writers upon the Sundew, to which I shall again recur, will give a fresh impetus to observers of similar phenomena; and the list of fly-catchers will, doubtless, receive many additions. The vegetable fly-traps fall naturally enough into three groups—the first containing such plants as by their viscidities attract and retain small winged or other insects; the second embracing such as by their structure are peculiarly fitted to retain the insects which they have, so to speak, unconsciously entrapped; and the third, and most remarkable, including such species as effect the capture of the insects by a definite, special, and, I may say, sensitive contrivance. I shall treat of these in the above-mentioned order. The species which exude a viscid matter from the stem or leaves are very numerous, and need not be enumerated. Among them, however, the *Silene muscipula* is noteworthy as possessing this viscidities in a remarkable degree, whence its specific name: it is especially the top of the stem of this species which is glutinous, and which retains small flies and other insects which settle upon it. The same thing is noticeable in our English *Silene noctiflora* in a somewhat less marked degree; and the English name for the genus, "catch-fly," as well as the French, "gobe-

THE FLOATING GARDENS OF MEXICO.

monche," refers to this peculiarity. This viscosity is occasionally turned to account, as at the Cape, where, according to Thunberg, *Roridula dentata*, a plant allied to the Sundews, is hung up in country houses for the purpose of catching flies; in Georgia and Florida, also, a beautiful shrub, *Bejaria racemosa*, is known as "fly-catcher," and branches of it are collected in flower and used for a similar object, the racemes being remarkably glutinous.

The Pitcher Plant.

Passing on to our second group, we shall find it mainly, though not exclusively, composed of "pitcher-plants" of various descriptions. In the true Pitcher-plants (*Nepenthes*) insects are frequently found drowned in the fluid contained in the pitchers; many, no doubt, being detained as prisoners on account of the difficulty of egress, the margin of the pitcher turning inwards, and forming a peculiar inverted rim, which is toothed at the edge; the teeth, of course, meet any insect which is making its way out of the pitcher. In some species, as in *N. ampullaria*, this inverted rim is very broad, and projects a long way into the cavity of the pitcher, forming a trap in which numbers of flies and other insects are taken. Nor is this rim the only hindrance to their escape. In the common species, *N. distillatoria*, and others, the base of the inside of the pitcher is covered with reversed glands, which hinder their exit in a manner similar to that which is effected by the reversed hairs of the *Sarracenias*. Even animals are occasionally caught in the pitchers of some of the larger species: Mr. St. John tells us of a dead rat having been found in one of those of *N. rajah*, a gigantic species, native of Borneo, from one pitcher of which four pints of water were taken! Rumphius says that various little worms and insects crawl into the orifice and die in the tube, "except a certain small squilla, or shrimp, with a protuberant back," which lives there. In the species of *Sarracenia*, the pitcher-like leaves are smooth inside towards the top, but the lower part of the tube is lined with hairs, which all point in a downward direction; at their base is a sweetish watery secretion. Attracted by this, the insect enters the tube, finding no obstacle to its downward course; but when it attempts to return it is opposed by the points of the hairs; and unless it can escape by perpendicular flight (a rare occurrence) it perishes miserably in the liquid, after repeated efforts to escape. This peculiarity, common to the whole genus, is especially manifested in *S. variolaris* and *S. rubra*. The insects appear to be induced to enter the tube in the first place by a sweet viscid substance, which exudes from it near the mouth. In South Carolina the leaves of these species are sometimes employed as fly-catchers; and with such success that the tube is filled in a few hours, where flies are abundant, and the quantity of water it contains is insufficient to drown the prisoners, so that more has to be added for that purpose. Even butterflies are occasionally found among the contents of the tubes; and Dr. Macbride states that he has observed among them the fragments of a large *Gryllus* and several *Gyrini*. The same writer remarks that spiders descend into these tubes, probably for the purpose of preying on the imprisoned insects, being enabled to escape by the assistance of their threads; and that a small species of *Phalæna* appears to take shelter in them during the day, and is enabled to ascend at pleasure, perhaps by some peculiar structure in its feet. The putrid masses of insects in the tubes, which are often so dense as to render the swamps where they grow very offensive, usually contain one or more maggots in a very active state; and Dr. Macbride ascertained that a large fly was accustomed to make use of these masses as a rearing place for its larvæ. *S. flava*, although a larger, is a less destructive species, owing probably to the more spreading throats of the tubes; the orifices of those of *S. psittacina* are very small, notwithstanding which insects find their way in, and their chance of escape is even less than in the other species. A Californian plant of the same order, *Darlingtonia californica*, has leaves of a similar description in form and internal clothing; and each pitcher has usually at the bottom a layer of from two to five inches of the remains of insects—from minute beetles to large feathery moths—closely packed into it. Mr. Robinson states that the pitchers are regularly used in the houses in summer as fly-catchers. In cultivation in this country the plant is equally attractive and destructive, especially to blue-bottles, which keep up a buzzing noise for about half an hour after their entrance into the pitcher, and then die. What the attraction is appears doubtful, as the plant is scentless; and the entrance to the pitchers is almost concealed by two curious reddish appendages which it possesses. The third genus of the order, *Heliamphora*, a native of Guiana, has similarly constructed pitchers, and acts in the same manner. It is both remarkable and interesting to find among the *Rosaceæ*, an order considerably removed from the *Sarracenias*, an Australian plant, *Cephalotus follicularis*, with very similar pitchers, furnished with reflexed hairs like those I have been describing, and also acting as an insect trap, the victims in this case being principally ants. And in a yet more widely separated family, the *Araceæ*, we have in *Arum crinitum* (or *muscivorum*), a native of

Minorca, a trap of the same class, although this plant possesses no pitchers. The spathe is covered inside with red reversed hairs, which are more crowded towards the base, so as almost to close the throat; the spadix, too, has remote violet-coloured bristles scattered over it. The flowers smell strongly of carrion, and flies are thus enticed to enter it; but the reversed hairs prevent their return, and they are there starved to death.

Sundews and Venus's Fly-trap.

Passing on to our third and most interesting group of fly-traps, it may be well to preface our notice by a brief *résumé* of Mr. Bennett's recent observations upon our common Sundew (*Drosera rotundifolia*). The assertion that this species captures insects has been doubted and even denied; but Mr. Bennett appears to have placed its truth beyond the possibility of doubt. He placed upon a leaf, at that time quite unencumbered, a very small species of thrips, which made violent efforts to escape, but only succeeded in entangling itself more completely. After about three hours its struggles ceased, and the glands, which had previously only slightly converged, began to bend over, and point the knobs at their extremities towards the insect. This experiment was made in the evening, and by the next morning almost every gland of the leaf was pointing towards the object in the centre, forming a dense mass over it. A second experiment was tried with a small piece of raw meat, and the same phenomena manifested themselves, although somewhat less rapidly. On other leaves a minute piece of wood and a fragment of worsted were placed, but in neither of these cases was the least change perceptible after the lapse of a considerable time; so that it would appear as if the organised structure of the fly and of the raw meat had some power of exciting this motion which is not possessed by matter of an inorganic description. These experiments are almost precisely similar to those made by Roth, nearly a hundred years ago, with the same results, upon this species and also upon *D. longifolia*; and Withering states that a Mr. Whately, in 1780, made various experiments with a pin, upon which he says that the glands contracted. Foreign species of *Drosera* possess the same peculiarity. *D. pallida*, a Swan River species, closes its leaves upon insects with great rapidity, and the same phenomenon is manifested by *D. sulphurea*, another Australian species. Royle says that the glandular ciliæ of the viscous leaves of *D. lunata*, an Indian Sundew, close upon flies and other insects which happen to light upon them; and many of the Cape species of *Drosera* have the same peculiarity, especially *D. trinervis*, which catches and retains the insects, when absorption commences, and the juices are completely drained by the many mouth-like glands, leaving in a short time nothing but small portions of dust.

The Venus's fly-trap (*Dionæa muscipula*), which Dr. Burdon Sanderson's recent experiments have brought into prominence, is too well-known to need more than a reference. The two lobes of the leaf close upon each other when one of the three bristles upon the upper surface of each is touched, and thus insects are frequently captured. Dr. Curtis says: "The little prisoner is not crushed and suddenly destroyed, as is sometimes supposed, for I have often liberated captive flies and spiders, which sped away as fast as fear or joy could hasten them. At other times I have found them enveloped in a fluid of mucilaginous consistence, which seems to act as a solvent, the insects being more or less consumed in it."

Orchids and Grasses.

We pass now to a very different class of plants—the *Orchidaceæ*. The important services which insects render to the fertilisation of a large number of species is well known, and the remarkable arrangement which we are about to mention is probably a provision for that end. *Caleana nigrita* is a small terrestrial Orchid of the Swan River colony, discovered by Drummond in 1832. The following extract from an unpublished letter, in which he communicated his discovery to the great Robert Brown, will explain the remarkable manner in which this species acts as a fly-trap:—"The lower lip is shaped like that of a *Calceolaria*, and is about large enough at the lower end to hold a musket-ball. The part to which the anthers are usually attached in *Orchidææ* (the column) is lengthened out and forms a lid, which exactly closes the lower lip. When the plant is in flower the lid rises up, and the moment a fly or other small insect alights on the flower the lid makes a sudden revolution, inclosing the insect in the lower lip as in a box. This curious Orchid grows about half a foot high; it has a single leaf about three inches long, lying on the ground, smooth, lance-shaped, and of a fine red colour; it has a small bractea of the same colour on the stem, about half an inch below the flower. There is only one flower on each stem; the lower lip is of a waxy yellow colour, and transparent, so that it shows insects moving about inside, when held between the eye and the light. Every other part of the flower is of a dingy red; the inside of the lip is of a very dark red approaching to

black, covered with minute glands which secrete a viscous substance like honey, apparently for the purpose of attracting insects." Among the Grasses we find an example of a fly-trap in *Leersia lenticularis*, a native of Virginia, North Carolina, &c. Pursh appears to have been the first to observe it catching flies, and he communicated his discovery to Dr. Barton, who thus refers to it:—"The glume or corolla consists of two valves, a character which belongs to all the species of the genus *Leersia*. In the *Leersia*, which is the subject of my observations, the glume is of an orbicular form, inclining to lenticular, and is much larger than in any of the other American species that are known to me, or than it is in the *Leersia oryzoides* of Europe and America. The edges of the valves are very distinctly ciliated, or furnished with a number of fine teeth or delicate spinules. It is this ciliate structure that enables the plant to perform the business of a *Muscicapa*. When a small insect insinuates itself between the valves (probably in pursuit of a honeyed fluid), the valves close upon it, the spines enfolding each other, thus retaining the insect."

Apocynum and Asclepias.

The plants of the orders Apocynaceæ and Asclepiadaceæ are peculiarly fitted by the structure of their flowers to act as fly-traps, as will be seen from the following description of one of them, *Apocynum cannabinum*, a native of the United States. The five anthers converge around the stigma, and slightly adhere to it by their inner face, a small space being left between each. "When a fly inserts its proboscis between these anthers to plunder the honey, they converge closer, and with such violence as to detain the fly, which thus generally perishes." Such is Dr. Darwin's account, as published in his "Botanic Garden" in 1799, and this has been substantially confirmed by later writers. Curtis gives a more detailed account, and explains the capture in a somewhat different manner. He says that, the space between the anthers being wider at the bottom than at the top, the flies insert their proboscides at this wider opening, and attempt to withdraw them in an upward direction through the upper part of the slit, which is too narrow to permit them to pass. Perhaps both observers are correct; at anyrate, there can be no doubt as to the efficacy of the plant as a fly-trap, as a Belgian horticulturist has lately advocated its cultivation for that purpose. Dr. Barton observed that the flowers of the Oleander, another Apocynaceous plant, entrapped insects in a similar manner. In the Asclepiadaceæ it is clear that flies and other insects render important service in assisting fertilisation. For a detailed account of the mode in which this takes place reference should be made to a paper published by Mr. Mansel Weale in vol. xiii. of the Linnean Society's Journal. It is sufficient to note for the present purpose that this writer noticed that, on placing the blossoms of *Gomphocarpus physocarpus*, a Cape Asclepiad, in water, numbers of flies, attracted by the nectar, got attached to the stigmatic glands, and appeared unable to release themselves. "On allowing the flowers to remain until completely withered, I ascertained that the flies had not sufficient strength to extricate themselves, and eventually perished with the flowers." The remains of legs of small moths and other insects were also found adhering to the stigmatic glands. Dr. Barton, of Philadelphia, observed that some branches of *Asclepias syriaca*, another member of the same order, which he had gathered, entrapped sixty or seventy flies in the course of a few hours, many of them being caught by the proboscis, others by the legs. Some of the larger ones were able to disengage themselves; others only succeeded in doing so at the loss of a limb; while many were unable to escape, and ultimately perished. The pollen-masses which are characteristic of Asclepiads are removed by the visits of insects, and applied to the stigma, so that the latter play an important part in the fertilisation of these plants. Mr. Riley, the State entomologist of Missouri, has lately stated that bees, when they become excessively troublesome, may be destroyed by planting *Asclepias syriaca*, which is much visited by them; the wax-like pollen-masses adhere firmly to their hair and claws, and so impede their motions that many drop to the ground and die. Dr. Barton also observed that the common tropical *A. curassavica* captures insects in the same manner.

Such is, I believe, a summary of what is known regarding these vegetable fly-traps. Should it be inquired what purpose is served by so remarkable a provision, is it not, I think, difficult to see three ends which are obtained by it. In the first place, these plants must in some districts play an important part in preserving the balance of life, and in preventing the too rapid increase of insects. Should this seem exaggerated, it must be remembered that in some parts of the United States the river banks and sandy fields are covered "for hundreds of acres in close connection" with various species of *Asclepias*; the *Sarracenias* abound in the swamps of North America, and contain so many insects in their leaves that their putrescence sometimes becomes very offensive. Secondly, it appears that in some instances, at any rate (e.g., the *Droseras*), the animal food thus obtained is of benefit to the plant; and it is not improbable that future obser-

ventions may show that all the leaf fly-traps serve this purpose. The third, and most important of all, is the service rendered by the insects to fertilisation in the case of the flower fly-traps. It is an ascertained fact that in many instances the agency of insects is absolutely necessary for the fertilisation of certain plants; and it would certainly appear to be so in some of the instances which are cited above. It may be well, in conclusion, to enumerate the plants which act as fly-traps, with their native countries, so as to show at a glance their distribution and the families which produce them; our first group of species, which simply retain insects from their viscosity, is excluded from this list:—*Sarraceniaceæ*. *Sarracenia*, various species, (North America); *Darlingtonia californica* (California); *Heliamphora nutans*, (British Guiana).—*Droseraceæ*. *Drosera anglica* and *D. rotundifolia* (Britain, Europe, West Asia, America, Columbia); *D. trinervis* (South Africa); *D. lunata* (East Indies); *D. pallida* and *D. sulphurea* and doubtless many other species (Australia). *Dionæa muscipula* (North Carolina).—*Rosaceæ*. *Cephalotus follicularis* (Australia).—*Apocynaceæ*. *Apocynum androsæmum* (North America); *Nerium Oleander* (East Indies).—*Asclepiadaceæ*. *Asclepias syriaca* (America and Canada); *A. curassavica* (Tropics); *Gomphocarpus physocarpus* (South Africa); and, doubtless, many other plants of this order.—*Nepenthaceæ*.—Various species of *Nepenthes* (Indian Archipelago, Continental Asia, Ceylon, and Madagascar).—*Araceæ*. *Arum crinitum* (Minorca).—*Orchidaceæ*. *Caleana nigrita* (Swan River, Australia).—*Graminaceæ*. *Leersia lenticularis* (North America).—[Although the above article by Mr. Britten in the *Field* is calculated to widen our views and make us more observant in this interesting, and it may be important, matter, the probabilities are that a very much greater number of plants than he mentions possess this curious property of fly-catching. Gardeners, who have better opportunities of studying living plants than botanists or any other set of men, may throw much light on this subject in the future, as some of the most famous fly-catchers are popular stove and greenhouse plants, and the *Apocynum* is a pretty border-flower. The North American Asclepiads are also quite hardy in our borders, and as for the as yet very rare *Darlingtonia*, it will probably prove hardy in the south of England, as we found it growing pretty high on the foot-hills of the Sierra Nevada, in places deeply snowed over in winter. The *Droseras*, hardy and tender, are, we think all capable of cultivation. The hardy ones are not usually considered so, because a bog or swamp is rarely successfully imitated in our gardens.]

THE KITCHEN GARDEN.

OLD GARDENS RENOVATED.

LAND under cultivation for the production of kitchen-garden crops forms no exception to the general rule of soil being unable to bear, for an indefinite period, a repetition of the same or a limited succession of crops. True, there are frequently local causes in the shape of natural superiority and greater depth of soil, accompanied with deep cultivation and a judicious rotation of cropping, such, for instance, as we see carried on by the London market-gardeners in the valley of the Thames and other places, where the soil is a rich, deep, alluvial deposit, cultivated on that all-essential principle of deep cultivation, with a liberal use of manure, and the return, as far as possible, of the soil's own production in the shape of the refuse vegetable matter worked deeply into the soil in the operation of trenching. But, with all possible natural advantages, assisted by the most skilful and intelligent system of cultivation, the time comes when the land gets tired, and becomes less profitable—a condition best described as wanting rest. Such is the state of very great numbers of old private gardens, where too often every load of manure required by the gardener is meted out with a grudging hand. The expedient not unfrequently resorted to, is the making of a new garden altogether. When the area required is large, say from 10 to 20 acres, this is in all probability the best course when a suitable site can be got; but even where such is the case, the making of, and inclosing with walls, a kitchen-garden is a costly affair. But it often happens that the existing garden is placed in the only situation available; where such is the case, and more especially if the area is not too large, and the material in the shape of new soil is obtainable,

Renovation

is the only course to follow. Introduce from 8 to 12 inches of new soil. Within an easy distance from large towns, where building operations are in progress, the top spit from Grass

land can frequently be got for little more than the cost of carriage; but in country districts it is not so easily obtainable. No one is fond of breaking into Grass land and removing the best of the soil in such quantity as the extent this operation will require. I must confess that I never yet removed from a pasture, or meadow, the comparatively small quantity of turf required for making or renovating a Vine border without feeling that it was making a sacrifice, even if an unavoidable one; and, before commencing, it is as well to see if the material can be got from any other source. Where there is common land that can be got at within a reasonable distance, the thing is simple enough; such failing, there is yet another source. In many country districts, on the sides of the roads, there are continuous banks of earth, the accumulation of years of road-scrappings and ditch-scurings, still increasing, and grown over with a luxuriant sward of Grass. These said accumulations do very great injury to the roads, above which they are in many places from 1 foot to 15 inches higher, preventing most effectually the water from getting away. In the adjoining county of Hertfordshire this is the condition of the roads for scores of miles in any direction. The gritty character of these road-side accumulations renders them for some soils even superior to the surface soil from cultivated land. Old gardens are greatly benefited by a dressing of good sound clay, or marl.

Draining and Trenching.

When the question of material for the renovation has been settled, the first essential is to ascertain that the drainage is efficient. Even where there is little apparent stagnant water in the soil, it frequently happens that a more complete system of drainage would greatly improve the land in several ways, by rendering it much more workable at all times, as well as allowing the production of spring crops much earlier. Then as to the depth of the drainage. This is a subject that for the last thirty years has received the attention of those connected with land cultivation on both farm and garden. Various depths have found advocates, from 2 feet 6 inches up to 6 feet. For most soils a medium depth, between the two extremes, will be found nearest the mark. But any uniform depth of drainage for soils of the different descriptions, such as are found in almost every parish in the kingdom, is about as inconsistent with common sense as it well can be. For all practical purposes, it will be sufficient to say that the bottom of any drain should be something like 9 inches below the pan, or stratum, that holds water; and, for a garden, something more is required than the simple pipe-drain alone, inasmuch as roots of the fruit trees, and some culinary vegetable crops, such as Beet, are subject to get down into the pipes and choke them. This is a matter that should be guarded against. After the pipes are laid, 6 inches of scoria, brick rubbish, broken stones, or flints, should be laid on the top; such not being available, faggots to the same depth should be used. This, in a great measure, prevents the danger of root-choking, for, even if the pipes were grown up with roots, the material above would act as a drain. To render the drains more perfect before the earth is filled in, there should be two inches of straw, Gorse, or hedge dressings placed over the drainage material already in, and then fill up. If the new soil used is of such description as to admit of its being incorporated at once with the soil already existing, this should be done by commencing at one side, and regularly trenching the whole garden right through, mixing the new soil well with the old to the entire depth the ground is stirred, adding at the same time a liberal dressing of manure. The question of depth in this operation of trenching will altogether depend upon the natural depth and character of the soil, and also the depth that has been gone to in previous trenchings. If the sub-soil is bad or inferior, no portion of it should be brought to the surface; but a few inches of it may with advantage be stirred and left where it is for the present; the soil above it, and the essence of the manure washed down by rains become mixed with and gradually improve it by the time the land again requires trenching. In, say, three years, those few inches of bottom soil can be brought to the top, and a little more of the bottom loosened up and left as before. Where the sub-soil is ordinary clay, a couple of inches at this and every subsequent time the land is trenched, may with advantage be brought to the top; but,

where this is done, the work should be carried out in the autumn, or early winter, so as to allow of the clay getting mellow, and in a fit state to be forked in previous to the time of cropping.

Re-planting and Re-cropping.

As the work proceeds, any old useless bush fruits, such as Gooseberries and Currants, that are too far gone to be of any further service, should be destroyed, as also worn-out unfruitful Apples, Pears, Plums, &c.; but, in this removal of fruit trees, let there be due consideration as to the requirements of the spot, and what there exists to supply their place, remembering that however unsightly a tree may be, if it be fruitful it is of more use than the beautifully symmetrical tree, that is not in bearing condition. Many a gardener has found when too late his mistake in removing unsightly trees before he has got others in bearing condition to supply their places. This is also an excellent opportunity for root-pruning any trees that are too vigorous; but in the case of such the operation should be completed not later than the end of January, or earlier if possible. I never yet saw root-pruning done late in the season without serious injury being the result. Wall trees at the same time should receive attention; if any require removal or replacing, it can be done now with advantage, as, when there is a general loosening of the soil to a depth equal to or greater than that required for the planting of trees, it prevents the occurrence of the serious injury that frequently happens to newly-planted trees, especially of considerable size, where, in planting, the soil is loosened for a greater depth, in the space their roots occupy, than in the surrounding ground. Where such is the case, if the soil is at all of a retentive nature, it will at once be seen that the space where the soil has been removed, and which is occupied by their roots, will act for a time as a drain to the surrounding ground. Unless in very light porous soils, no tree, however common, except a Willow, or other water-loving subject, should ever be planted, unless the surrounding soil is stirred as deep as it has been moved for the reception of the roots of the tree being planted. This renovating process will naturally cause an upset of many crops that cannot well be spared—things of a permanent character, such, for instance, as Asparagus. The ground occupied by this vegetable should not be disturbed until fresh beds have been made and got into bearing condition; this will take two or three years. The ground selected should be such as has been cropped with something as different as possible; say, where Gooseberries or Currants have been growing for a considerable time. If the soil is of a fair description, it need not all be removed to the full depth of the beds, as it is sometimes done; if 18 inches be taken from the surface, and 2 feet of new soil and manure be brought in its place, and well incorporated with 18 inches of the under soil, it will make ample preparation for growing this vegetable well. In the working of old gardens, a great deal may be done to prevent their becoming exhausted by continually, as opportunity occurs, adding something to make up for the continuous drain on the fertile constituents of the soil by the different crops that are taken from it yearly. Soils of a naturally light description have a tendency to become sterile much sooner than those of a heavier, more retentive character. Without the continual addition of the necessary, but not over-plentiful manure, to eke out which large quantities of leaves are generally used, in the course of time soil of this character gets exhausted. If, instead of year after year working on the exhausting system, no opportunity be lost of adding even in small quantities new soil whenever obtainable, a garden may be kept for almost an indefinite time, without getting in such condition as to require an operation of such magnitude as the addition of new soil in the quantities necessary, where complete exhaustion has taken place. It frequently happens that stable manure is used, to the exclusion of every other kind; for light, dry, sandy soils, cow or pig manure used alternately is preferable, and, with such, the soil will not so soon become exhausted. The high temperature which stable manure is often allowed to get to before use renders it little better than so much decayed vegetable matter. If the manure, of whatever description is used, could be taken fresh, and mixed with an equal proportion of loam or dry road-scrappings, it would be much more useful.—THOMAS BAINES.

MESSRS. F. & A. DICKSON AND SONS' UPTON NURSERIES, CHESTER.

AMONGST the principal provincial nurseries this ranks as one of the most extensive and important, and one to which, at all seasons of the year, a visit must prove a source of great pleasure and instruction to all who take an interest in horticulture. In few nurseries is such an innumerable variety of plants to be found, and yet the most systematic order is observable in the arrangement of each department. The principal entrance to these nurseries is at the north-west extremity, about a hundred yards from the Bache Pool, which is one mile from Chester, on the main road to Birkenhead. From the entrance gate a fine broad drive, defined by a neatly kept Grass verge on either side, runs between borders containing many thousands of the finer varieties of variegated and green Hollies of different sizes, *Cupressus Lawsoniana*, *Thuja borealis*, *Wellingtonias*, *Cryptomerias*, *Deodaras*, *Golden Yews*, and

the finer kinds, of all sizes, many of them specimens in the finest health, well set with bloom-buds; another to *Azaleas*, amongst which we observed a number of large and beautifully-trained pyramidal plants, suitable for exhibition, besides many hundreds of plants of lesser size, full of vigour; another large house is filled with winter-flowering plants, such as *Ericas*, *Epacris*, *Cyclamens*, *Primulas*, *Daphne indica*, *Bouvardias*, *Cytisus*, *Deutzias*, *Solanums* (full of berries), and a number of other kinds, either in flower or covered with bloom-buds for later flowering. Roses in pots occupy another house, and consist of strong healthy plants of the choicest Tea-scented and Noisette Roses, as well as all the best and newest varieties of Hybrid Perpetuals, established in pots for forcing. In addition to these there are a number of other houses and an immense number of frames, &c., used for propagating and growing different kinds of plants, all fully stocked with healthy well-grown stuff. New houses

Specimen Conifers in the Upton Nurseries, Chester.

many others of the best kinds of Conifers and shrubs in large numbers; by following this road some distance, the offices and packing sheds, &c., are reached. The outer sides of the latter are skirted by a low rock-work, upon which are planted fine collections of the choicest Alpines, hardy Ferns, &c., and the walls are covered with the best varieties of green and variegated Ivies, &c., thus affording ample opportunity for parties to select for themselves, at the same time giving a clothed and neat appearance to the buildings at all seasons. Near this are the glass-houses, frames, pits, &c., covering about two acres of ground; these are filled with a great variety of exceedingly healthy and well-grown plants of all kinds, including those of recent introduction. Separate houses, of large dimensions, are devoted to stove plants and variegated-oliaged plants, all in perfect health; others to New Holland plants; another to Ferns, Palms, &c., in endless variety; another to *Camellias*, containing many thousands of plants of

and frames are being added almost every year; and, in some newly-erected span-roofed frames, we observed a splendid lot of young *Camellias*, *Azaleas*, &c., in the most promising condition. Large numbers of small propagating frames for increasing the stock of hardy Conifers, *Rhododendrons*, shrubs, climbers, &c., containing many thousands of young plants, are also to be seen. These plants are, when fit, transferred from their frames to small brick beds, which cover a large area of ground near the offices, and they are transplanted there for one or two seasons, previous to being planted out into the open quarters in the nurseries. In front of the greenhouses there are lines of geometrical flower-beds, which are filled at this season with *Hyacinths*, *Tulips*, and other bulbous roots, and spring-flowering plants, such as bedding *Pansies*, *Daisies*, *Primroses*, *Hepaticas*, &c.; in summer these are re-filled with the better kinds of bedding plants, succulents, &c. Opposite these beds there is a border filled with all the newest and most

select kinds of Conifers and hardy evergreen shrubs, planted so as to contrast in colour, and at right angles run other two borders planted in a similar manner; at the end of the walk, which divides the borders last named, there is a most beautiful and artistic specimen of artificial rock-work. Here are a pair of very large handsome specimens of Irish Yews, and not far distant stands one of the finest formed specimens of *Araucaria imbricata* we have seen. It is some 30 feet in height, and is singularly robust in habit, and noble in character. This fine tree forms a prominent feature in the annexed illustration. Leaving this part of the nurseries, we come upon large quarters of choice named hybrid *Rhododendrons*, *Azaleas*, and other American plants, which are grown here in great numbers, and appear to thrive admirably in the natural loamy soil, without peat, which is usually considered essentially necessary for their growth. This, however, proves they will grow well in light loamy soils, and plants so grown have many advantages over those grown in rich peaty soil, as they are of a hardy nature and adapted for removal to places where peat is costly or difficult to procure. Next we come to a large breadth of all the new, rare, and choice Conifers in large and small plants. We find great care has been bestowed in the selection of these, and only such as prove to be thoroughly hardy, and in every way desirable, are cultivated. Amongst these we noticed many hundreds of large and handsome specimen *Cedrus Deodara*, *Cupressus Lawsoniana*, in its many forms, *Picea Nordmanniana*, *P. nobilis*, *P. lasiocarpa*, *Thuja borealis*, *Abies Clanbrassiliana*, *Cryptomerias* of sorts, *Wellingtonias*, and many others, all of which have been regularly transplanted and are calculated to give immediate effect. Adjoining this, is, what is known as the plunging-ground, where *Ivies*, *Clematis*, *Wistarias*, *Pyracanthas*, *Ampelopsis*, *Cotoneasters*, *Honeysuckles*, *Bignonias*, *Escallonias*, *Magnolias*, and other plants suitable for covering walls, trellises, &c., are kept in pots; these are plunged in beds. Many shrubs are also kept in the same way, such as *Arbutus*, *Sweet Bays*, *Buddleias*, *Escallonias*, white and yellow *Broom*, evergreen *Oaks*, *Forsythias*, *Euonymus*, &c. Plants so treated have the advantage of being safer for removal, and can, without risk, be transplanted at any season of the year. The culture of fruit-trees has long formed a prominent feature in these nurseries, and upon this department especial care is bestowed to render the collection as perfect as possible with regard to kinds, growth, and superiority of training. Acres of ground are covered with these, in standards, trained and untrained, horizontal-trained trees for espaliers, and all other forms adapted for the different purposes for which they are required. We were particularly struck with the pyramids, which really deserve that designation. The same care is taken with the horizontal-trained trees, and all the other forms of training, to get them as near perfection as possible. A finer lot of fruit-trees we could not wish to see in any nursery. Vines are most extensively and successfully grown here; and, at the time of our visit, we saw thousands of fine, strong, well-ripened canes of the leading kinds, in excellent condition for immediate fruiting in pots, and for planting out in Vine-borders in the usual way. The collection of standard and dwarf *Roses* grown here is something marvellous, and, the soil being admirably adapted to their growth, the plants appear very strong and healthy. Messrs. Dickson have been very successful exhibitors of cut *Rose* blooms at many of the leading shows, and they hold a great number of prizes awarded to them for their flowers during the past few seasons.

Standard *Limes*, *Horse Chestnuts*, *Elms*, *Cratægus*, *Purple Beech*, *Oaks*, *Maples*, *Platanus*, *Poplars*, &c., are also grown in many thousands, suitable for planting in ornamental belts or plantations, and also for single specimen trees. All the better kinds of flowering shrubs are to be found in great quantities, and this is a very desirable class of plants for mixed borders and plantations, as they furnish an abundance of flowers during the whole of the growing season, contrasting prettily with other plants and shrubs; they should, therefore, be planted more extensively than they are at present. Immense numbers of evergreens are grown, such as common and *Portugal Laurel*, *Laurustinus*, *Hollies*, *Box*, *Berberis*, *Rhododendrons*, *Yews*, *Aucubas*; and you see large breadths containing many thousands of each kind in the shape of

strong, bushy, healthy plants of all sizes. Forest trees, in all stages of growth, both as seedlings and transplanted trees, cover very many acres, and consist of many millions of all the leading kinds, such as *Larch*, *Scotch Fir*, *Spruce*, *Austrian* and *Corsican Pines*, *English* and *Turkey Oak*, *Beech*, *Birch*, *Sycamore*, *Ash*, *Hazel*, *Poplars*, *Chestnuts*, &c. They are planted thinly upon the ground, and are uncommonly strong, well-rooted, healthy trees. This portion of the nurseries, standing upon one of the highest and most exposed parts of *Cheshire*, renders the trees very hardy and particularly well adapted for transplanting to any part of the country. Judging from the enormous quantities of transplanted *Thorns* or "Quicks" grown here, the demand for these must be unusually great, yet we understand that the number required increases from year to year. Near the residence of the late Mr. Francis Dickson (who was the founder of this old-established and well-known business, and who was considered to be one of the most skilful nurserymen of his day) are some noble specimens of the *Araucaria*, *Picea nobilis*, *Picea Pinsapo*, *Picea Nordmanniana*, *Wellingtonias*, and other handsome Coniferous plants of early introduction. Time would not admit of us taking further notice, but there are many other objects well worth inspection.

In the seed department, which is even more extensive than that of the nursery, the greatest attention is exercised to have everything true to name and the best of its kind, evidence of the truth of which may be found in the case of Messrs. Dickson's First and Best Early Pea, which has hitherto maintained the high character it at first received amongst a host of rivals. A new seed warehouse and offices, of imposing and somewhat antique appearance, and on an extensive scale, have recently been erected in the principal street in *Chester*, and much judgment and good taste have been brought to bear on the internal arrangements, so as to facilitate the execution and despatch of business. In several large warehouses adjacent are stored immense stocks of agricultural seeds, for the superior excellence of which, as well as all other seeds, Messrs. Francis & Arthur Dickson & Sons have, as is well known, achieved a wide reputation. One of the warehouses, we observed, was filled with hundreds of sacks of *Turnip* and *Mangold* seeds, amongst which we particularly noticed large bulks of their Improved *Purple-top*, or *Defiance Swede*, *Globe* and *Long Red*, and their Improved *Yellow Mangolds*. *Natural Grasses*, *Italian* and *perennial Rye-Grasses*, *Clovers*, &c., were also stored in almost endless quantities. At various exhibitions a great many important prizes have been awarded for roots grown from seeds supplied by Messrs. Dickson, in different parts of the kingdom. Their mixtures for sowing down land to permanent pasture are, we learn, in great request, and are highly commended by all who have used them. It will, therefore, be seen that the nursery and seed business of Messrs. Francis & Arthur Dickson & Sons stands in the first ranks amongst extensive establishments of this kind in *Britain*.

We may add, that a more enjoyable and instructive day we have seldom spent, than that on which we visited the *Upton Nurseries*; and, if any of our readers should have occasion at any time to go to *Chester*, we would advise them to take advantage of Messrs. Dickson's courtesy and follow our example.

A New Fuel.—The *Belgian* press speaks in terms of praise of a new fuel discovered by a countryman named *Ramaeckers*, of *Schoonbeek*, near *Hasselt*. It is composed of vegetable earth, small coal, salt of soda, and water, in certain proportions. The experiments made at *Bruges*, *Liège*, *Namur*, and *Brussels*, have been generally successful. A manufacturer at *Louvain* tried the new fuel in a fire-grate of a *Marinoni* steam-engine. He mixed three-parts of vegetable earth and one-part of small coal with a solution of $\frac{1}{2}$ lb. of salt of soda, in a trough capable of containing 61 lbs. of coal, and stirred these ingredients together till the composition acquired the consistency of mud. In a few seconds an intensely vivid flame swept round the boiler, producing so much heat that the manometer soon marked 4, 5, and 6 degrees, whilst the steam regularly carried on its motive function. Other experiments have been made in the use of this new combustible material by making it into balls and burning it in open grates with coal; and an opinion seems to prevail that a discovery has actually been made which will economise coal.

THE HOUSEHOLD.

EDIBLE STARCHES.

AN interesting paper on the subject of "The Edible Starches of Commerce; their Production and Consumption," was read a short time since by Mr. P. L. Simmonds at a meeting of the London Society of Arts. The lecturer pointed out that while the English use but one word to define all sorts of starch, even the minor classification of arrowroots, sagos, tapiocas, corn-flours, &c., the French have two words by which they distinguish the starch obtained from roots, stems, fruit, seeds, &c., from the amylaceous product obtained from cereals: the former they term *fecula*, and the latter they define as *amidon* or starch. The value of the edible starches imported into England, which was in 1860 £206,438, in 1870 amounted to £366,570, and in 1871 to £485,706. The production of European starches was shown to be trifling, as compared with that of tropical and sub-tropical countries, though considerable quantities are manufactured in this country from imported Maize (or Indian corn) and Rice, and sold under the name of corn-flour. The island of St. Vincent is the only arrowroot-producing colony that has kept steadily progressing, the quantity exported to the United Kingdom having increased from 11,436 cwts. in 1863, to 16,919 cwts. in 1870. In 1850 the shipments were only 3,573 barrels, and 7,493 boxes. The other West Indian Islands, though at one time exporting considerable quantities of arrowroot, have gradually decreased their production, and the quantity exported has in every case but that of St. Vincent, dwindled down to a merely nominal figure. In Brazil, considerable attention is given to the production and manufacture of edible starches. A large and varied collection of these was shown at the Paris Exhibition of 1867, comprising starches made from Pumpkins, Maize, Bread-fruit, white and yellow Manioc, Brazil Potato, Demerara Potato-yam, Banana, &c. A variety of the Manioc or Cassava, from the tubers of which feculas are mostly manufactured, the *Maranta arundinacea*, was introduced into India about 1840, and is now cultivated to a considerable extent, the arrowroot made from it being extensively used in India, and some of it shipped to Europe. The consumption of sago in the United Kingdom is stated as 52,000 cwts. in 1850, 179,825 in 1860, and in 1870 the aggregate of sago and tapioca received from Singapore was 344,000 cwts., representing a money value of £283,541. The Australian colonies were also noticed by Mr. Simmonds as arrowroot-producing countries, specimens of this starch manufactured in the colonies having been exhibited at the Paris Exhibition of 1867, and the London Exhibition of 1872. The Pacific islands appear to be very rich in the *fecula*-producing arums and other plants, and a considerable trade is carried on in various feculas in many of the islands. Africa also shares to a considerable extent in the production of arrowroot, but Cape Colony and Natal are the only two districts that export it in any quantity. The *Maranta arundinacea* is the species cultivated, and it has also been introduced into the Mauritius, whence specimens of arrowroot were sent to the Paris Exhibition of 1867.

RECIPES.

Stewed Pears.—Sixteen Pears, eight ounces of sugar, half a bottle of common claret, a little water, twelve cloves bruised. These are best cooked in a fish-kettle, no two pieces one on the other. Pare the fruit and split them in halves, splitting also the stems. Make a syrup of the wine, cold water, sugar, and cloves; let it boil five minutes, then lay in the halves of the Pears, and stew them gently for two or three hours till tender.

How to boil a Vegetable.—The rule is simple, but must never be forgotten. Every kind of vegetable intended to be served whole should, when put to boil, be placed at once in boiling water; and this applies especially to Potatoes and vegetables from which the outer cover has been removed. Now it often happens that Potatoes, &c., are, to save time, placed in cold water and left to boil gradually. It is just this which allows the nutritious matter to escape, and renders the meal unsatisfying. When, on the contrary, the water boils from the moment the vegetable is immersed in it, the albumen is partly coagulated near the surface, and serves to retain the virtue of the vegetable. The reverse is, of course, the rule for making soup, or any dish from which the water will not be drained. By placing the vegetables in cold water the albumen is slowly dissolved, and actually mixes with the water—a process most necessary for the production of nutritious soup.—*Food Journal*. [This advice is not sound throughout, as the true way to boil Potatoes in their skins is to put them in cold water at first.]

Peach Brandy.—Last season 10,000 boxes of Peaches which arrived in a poor condition in Baltimore on a Saturday evening were sold at five cents a box to a Peach-brandy distiller.

THE PRICE OF COAL IN ITS RELATION TO HORTICULTURE.

HORTICULTURE is a luxury to most people; but the time is at hand when it will become a necessity; to certain classes of society it has, indeed, already become so. To many more it is in a transition state, trembling, as it were, in the balance between luxury and necessity, but, to most it is, as we have stated, a luxury. Now luxuries, upon any occurrence of a rise in prices, can be done without, upon the first feeling of tightness in the domestic exchequer. This, a philosophical friend of mine, assures me, is the reason why gardeners, as a class, seldom share in the general rise of prices. Other better paid classes make money, gardeners spend it. And it is the money makers, not the money spenders, that are most liberally paid. It would be easy to diminish the philosopher's argument by carrying it to an extreme length; but, nevertheless, it embodies a general truth of great importance, the effects of which are felt throughout the entire field of horticulture. Production is, in fact, ever tied hand and foot to cost. This is true, not only in trade and commerce, but also in the domain of luxury, and especially in horticulture, which is trade, commerce, luxury, and fine art all in one. Whatever cheapens production fosters horticulture; whatever adds to its cost fetters it. Of the first we had a striking example in the abolition of the excise duty upon glass. Nothing in modern times has given such a vigorous stimulus to horticulture as free glass. It made huge conservatories, greenhouses, winter gardens, Crystal Palaces possible, and also brought the luxury of glass structures within reach of every thrifty artisan who cared to possess them. It has increased plants and their cultivators ten thousand fold. The tide of progress has flowed on, growing wider, broader, and higher, until now, when it has been arrested by the high price of coal. The coal famine, although of short duration, has raised the cry, "Halt! back!" over the entire field horticultural. It has well nigh doubled the cost of the production and preservation of tender plants and tropical or forced produce. The cost of heat—that most important factor in production—has been, in general terms, doubled. The consequence is that many have ceased to use it; some use half what they did before, to bring their expenditure within the old limits—nearly all use less; and the result is less horticultural activity, less progress, less produce. Nor does the evil of dear coal end here. It has raised the price of nearly all horticultural commodities, and thus limited the number of purchasers; plants and seeds are dearer than they were, and, therefore, fewer are bought; and so, if dear coal continues, it will mean choice fruits and vegetables at a higher price, and this, again, will limit the demand for them; and thus the coal famine checks horticulture on both sides, as it were. It checks production and limits consumption; and, by this compound compression, keeps demand and supply nearly abreast of each other, at a very low ebb. Were it not that the country is making money at an extraordinary rate, the evil effects of the coal famine must be still more keenly felt. As it is, there are but few gardens in the kingdom where the dear-ness of coal has not proved a barrier to progress—if, indeed, it has not quite stamped out some furnace fires, or hindered them from being lighted till a month or two later than usual. There is also a growing conviction that we have seen the worst of the coal famine, a conviction strengthened by a sight of the immense supplies piled at the different railway termini, and at the pits' mouths. For the future of horticulture it is to be hoped that this expectation will be confirmed. There is also great hope for horticulture in the substitution of other sources of heat for coal. Mr. Cowan's lime-kiln heating is an undoubted success. True, the philosophers say that it ought not to be so, that lime, being an inorganic substance, can generate no heat—that the heat of the coal is wasted in warming the lime that warms the boiler that heats the water; but the fact, nevertheless, is patent to all that, by placing a boiler astride a lime-kiln, thousands of feet of hot-water pipes are sufficiently heated to warm a whole series of hothouses with the caloric which would otherwise have been utterly wasted, whilst the lime drawn promises to pay the entire cost of the heating—a grand fact of immense importance to the present and future of horticulture. I also look hopefully to our thousands of acres of useless bogs in Scotland and Ireland. Surely, it is not too much to ask of the science and the commercial enterprise of the age, that they should warm the hothouses of the nation with compressed peat at a reasonable cost. Possibly, when these two things are done, it will be found that our lime-stone rocks, our numerous deposits of chalk, and our thousands of acres of neglected peat will prove to be amongst the most powerful stimulants to the advancement of that branch of horticulture which depends upon stoves and hothouses. But, should we remain much longer under our present deplorable dearth of heat-supply, I cannot but look forward to an increasing loss of interest in (and, in many cases, final extinction of) the culture of some of our choicest fruits, flowers, and vegetables. D. T. FISH.

GARDEN DESTROYERS.

A NEW POTATO ENEMY.

I WISH to say a few words about an enemy which threatens to lay waste one of Europe's most valued esculents—the Potato. For a long time North America has had to contend against two foes, which devoured the early shoots and leaves of the Potato, and thus destroyed the hopes of the farmer and gardener. These were beetles belonging to the same family as the Blister-fly, and named *Lytta atrata* (or *vittata*) and *Cantharis viniaria*. They can be kept within bounds; but of late a third beetle has appeared among us which really threatens to drive the Potato out of cultivation altogether. It bears the name of the Colorado Potato-beetle (*Doryphora decem-punctata*); and should it once reach the Atlantic coast, and be carried unobserved across the ocean, then—woe to the Potato-grower of the old country! A man must witness the myriad legions of this insect, and the ravages of its never-tiring larvæ, in order to form an idea of the terrible danger with which Europe is threatened. For myself, judging from the tenacity of life exhibited both in its larval and perfect condition, I have not a doubt that it will soon overstep the bounds of North America, and make a home for itself in other lands. Its true domicile is in the Rocky Mountains, where it feeds on a species of wild Potato, *Solanum rostratum* (or *Carolinianum*). No sooner, however, had the edible Potato (*Solanum tuberosum*) been planted by settlers at the foot of these mountains, than *Doryphora* attacked it greedily; the more largely its cultivation extended westward, the faster did its insect foe travel in an easterly direction, and scatter itself over the land. In the year 1859 it was located one hundred miles west of Omaha city, in Nebraska; in 1861 it showed itself in Iowa; in 1865, not only had it begun to devastate Missouri, but it had crossed the Mississippi in Illinois, everywhere leaving behind it flourishing colonies. In 1868 Indiana was visited; in 1870 Ohio and the confines of Canada were reached, also portions of Pennsylvania and New York; and its entrance into Massachusetts was notified. During the year 1871, a great army of these beetles covered the river Detroit in Michigan, crossed Lake Erie on floating leaves and similar convenient rafts, and in a very short time took possession of the country between St. Clair and Niagara rivers. Having got thus far, in spite of all efforts to stay their progress, there is every reason to believe that before long we shall hear of them as swarming in the streets of New York and Boston (as they already swarm in the city of St. Louis), and then their passage across the Atlantic is a mere matter of time. Moreover, the beetle, in its different stages, is so entirely unaffected by the extremes of heat and cold, of wet and dry, which it has met with here, that I have no doubt it will care as little for the changes of climate which occur in the temperate zone of Europe, and, once settled, will quickly become naturalised. The devastations of the Colorado beetle are all the greater from the fact of its propagating itself with extraordinary rapidity, several broods following each other in the course of the year. The first batch of infant larvæ appears towards the end of May, or, if the weather be mild, of April. In fact, scarcely has the Potato plant shown itself above the ground, before the insect, which has been hybernating during the winter, also wakes to life. The female loses no time in depositing from seven hundred to twelve hundred eggs, in clusters of twelve or thirteen, on the underside of a leaf. Within five or six days, according to the state of the weather, the larvæ escape from the eggs, and begin their work of devastation, which goes on for some seventeen days, when the little creatures retire below the soil in order to undergo the pupal condition. After a delay of ten or fourteen days, the perfect insect comes into being, and the business of egg-laying commences anew. In this way, according to recent observations, three broods follow each other; the last, as just stated, wintering below the surface of the ground. No description can do justice to the marvellous voracity of this insect, especially in its larval state. When once a field of Potatoes has been attacked, all hope of a harvest must be given up; in a very few days it is changed into an arid waste—a mere mass of dried-up stalks. At one time the cultivator indulged in the vain hope that *Doryphora* was a mere passer-by, that he would do his worst and then

move on, without becoming a permanent nuisance. Others, again, fancied that a hot summer and autumn, followed by a long drought in the ensuing year, tended to diminish its numbers. But it has been proved incontestably that the diminution was only due to the circumstance of many of the larvæ perishing through being unable to enter the ground hardened and baked by the great heat; plenty were left to continue the breed. Of the many nostrums employed for the destruction of this beetle, one only has shown itself to be of any value. I mean, dusting the plants with the highly poisonous substance Paris green,—a compound of arsenic and oxide of copper. However, setting aside the dangers of inhaling this deadly mixture while spreading it over the fields, there is the

Colorado Potato Beetle in different stages, from egg to perfect insect.

additional peril of impregnating the soil with it,—a peril which experiments carried out at Washington have shown to be well founded. There remains, therefore, only the plan of hand-picking, day after day, the eggs, larvæ, and beetles. But even this operation requires considerable care, for the juice of the crushed insect and its larvæ produces bladders and blisters wherever it comes in contact with the skin. If a wounded spot be touched by it, severe inflammation ensues, which is liable to pass into ulcers, and an application of it to the eye endangers vision to a very serious extent.

Fig. 1 gives an idea of the Colorado Potato-beetle in its different stages. The eggs are of a deep orange-yellow. The larvæ, on first emerging, are of a blackish hue, which passes quickly into a dark red, with a slight orange tint. On attaining their full size, the colour varies between orange, reddish-yellow, and flesh. At c, fig. 2, is shown the pupa; at

a. Colorado Beetle. b. Foot of ditto. c. Pupa of ditto. d. Wing-case, enlarged.

a the perfect insect, natural size; a foot is portrayed at b; a wing-case, considerably enlarged, at d. The ground colour of the latter is creamy-yellow (rahm-gelb), with five black longitudinal stripes, of which the third and fourth unite at the base. *Doryphora* does not by any means confine itself to the Potato. In places where that esculent is wanting, it will support itself on any other member of the Solanaceous order—the Egg-plant (*S. melongena*), the Tomato (*S. lycopersicum*), or the winter Cherry (*Physalis viscosa*). Indeed, in the northern parts of Illinois and in Wisconsin—incredible as it may appear—it has established itself in the Cabbage-garden as readily as in the Potato-field.

THE AMATEUR'S GARDEN.*

SPRING FLOWER BEDS.

WITH little trouble or outlay our flower gardens might be made to look gay during the spring months, instead of being blank and dreary. Gardens, which one has seen in summer as rich in colours as a kaleidoscope, if visited during the spring can hardly be believed to be the same. Now, when spring-bedding costs but a trifle, this should not be the case. When it is time to lift the plants that have flowered in spring to make room for those intended for summer-blooming, they may be planted in some back border, and when autumn comes round they may be lifted, divided, and re-planted in the flower-beds. This practice may be followed year after year, while others shed their seed, and their numbers are increased in that form. The first outlay is the principal one, as, with the exception of new varieties, the old stock will maintain itself. I have planted this season myself, in the centre of the lawn, a star-shaped bed; this I have filled as follows:—In the centre is a circle of Cliveden Purple Pansy, and the rest Cliveden Yellow; right and left of these is a large pair of beds, shaped like crossed compasses, these I have planted with blue Forget-me-not. Between the specimen shrubs are different-shaped beds, some circular; in these I have dark-coloured Polyanthuses in the centres, edged with Clevedon White Pansies. Then, I have a pair, shaped like a circle in the middle, the ends being two half-circles; the centres of these consist of *Viola cornuta*, and the two half-circles, which form the ground-work of the centre, are filled with variegated *Arabis*. The next are long squares (if I may so call them), with circles at the corners, and are filled with mixed Pansies; then I have some, formed like a Maltese cross, of variegated *Arabis*, with a square of *Viola cornuta* in the middle, where the points of the cross meet; then I have some of a circular form, with two square ends drawn out of each, in the circle are double scarlet Daisies, edged with *Viola lutea*, the ends being made to match; then I have some others of a diamond shape, filled with Auriculas. Besides the plants just mentioned, I have also Hepaticas, Tulips, Crocuses, Jonquils, &c., all of which tend to give my garden a gay appearance during the spring months.

A. HASSARD.

Upper Norwood.

WORK FOR THE WEEK.

PRIVATE GARDENS.

Stoves.—Maintain a temperature of 55° at night, and permit it to rise to 65° or 70° during the day with sun-heat. Plants of *Poinsettia pulcherrima*, whose beauty is past, should be removed to a dry corner and kept dry, but still in the stoves, or laid on their sides under the benches. Plants of *Hexacentris* done flowering, cut well back and induce them to go to rest. Give some weak manure-water to *Eranthemum pulchellum*, *Statice*s, and other soft-wooded plants coming into flower. Lay plants of *Lagerstrœmia indica* on their sides in a cool house. Plants of *Stephanotis*, *Allamandas*, *Passifloras*, *Clerodendrons*, *Cissus*, *Echites*, and other climbers, if required to bloom early, should be pruned, and syringed daily to encourage growth. The general stock of these, however, should yet remain at rest. Start a few roots of *Achimenes*, *Gloxinias*, *Caladiums*, and herbaceous *Gesneras* for early flowering; keep the majority, however, for later work and see that no damp comes in contact with them. Decapitate all long naked-stemmed *Dracœnas*; use the tops as cuttings, and place the pots containing the stumps on the floor along the passage in close proximity to the pipes, so that the heat therefrom may more hastily promote the production of fresh shoots. The shoots can be taken off as they attain the length of an inch or two and used as cuttings. This method economises room in the heated plunging material, which should be saved for more delicate subjects. Guard *Nymphœa* roots from the attacks of rats and mice; cats are the best and safest preventive against damage done by these vermin; and in order to encourage their presence a mouse or two should be given them in the place which they are desired to frequent; if this is done they will not fail to come again to look for more. Weasels are good friends to gardeners, and ferrets are useful for rat-catching; with traps and poison, and the other agents of destruction so familiar to most of us, their clearance may also be effected.

Pits and Frames.—Remove dead leaves from Auriculas, and

give the plants plenty of air whenever the weather is favourable; but guard against heavy rains, strong drying winds, and severe frost. Water sparingly, but do not allow the plants to flag, and towards the end of the month, when root-growth begins more actively, water them more freely. Shift *Calceolarias* and *Cinerarias*, if necessary; keep them cool, moderately moist, and free from greenfly. Introduce a few *Cinerarias* into the forcing house. *Car-nations* and *Picotees* can scarcely be grown too hardy, provided they were early potted and are well rooted; but they require to be protected from cold winds, rain, and severe frost. Little or no water should be given, except in very dry weather, and then only in the morning, and at a time when there is no danger from frost. Avoid as much as possible wetting the foliage, remove any decaying leaves, keep the plants thoroughly clean, and prepare the soil required for the plants to bloom in. It should consist of three parts good strong loam, and one of well-rotted manure, kept moderately dry and occasionally turned; it is generally a rule to prepare, in autumn, a sufficient quantity of soil to last through the year. This should be well mixed together, and laid by in a heap where it can be fully exposed and frequently turned. As the surface becomes frozen in severe weather, the crust should be removed, so that as much of the soil as possible may be subjected to the influence of frost; but the heap must be covered in wet weather. The loam should be carefully cleared of wire-worms; and, before using, a little coarse sand should be added to it. Remove any mould or decay that may be found on the stems or tubers of *Dahlias*. *Holly-hocks*, strong and healthy, should have abundance of air during fair weather, and keep them free from excessive moisture and decayed foliage. Late-struck cuttings will be found to winter best in a greenhouse or pit, near the glass, where they can have the advantage of a little fire-heat in damp or frosty weather. Cuttings from old stools may be propagated in gentle heat. From Pansies in frames remove the lights during favourable weather, but protect the plants from cold winds, rain, and frost. Dust with sulphur the foliage of any that may become affected with mildew, and remove decaying leaves. Give *Polyanthuses* in frames moderate moisture and free ventilation, and prick off seedlings, keeping them rather close for a short time afterwards. Pot a few *Ranunculuses* for early blooming, and sow some seeds in pans, which keep near the glass.

MARKET GARDENS.

The fine days that we have lately experienced have had a beneficial influence on market gardens. All hands have been set to work; those who cannot dig, trench, or shake up litter, place with the women and boys to loosen the soil amongst Cabbages, Coleworts, Lettuces, Parsley, transplanted Onions, and similar crops. Get August-sown Onion-beds thoroughly cleaned; women with half-sieve baskets, to put the weeds in as picked, soon go over a large space on a dry day. When finished, slightly dig or loosen the alleys, and transplant Lettuces or Cabbages therein. Get all empty quarters manured and trenched, throwing the soil into ridges 2 feet apart. Vacant ground under fruit trees manure and dig for Radishes, and be sure to have the trees thinned or pruned before the ground is interfered with. Radish beds sown early in December should be uncovered every morning, replacing the litter at night. Keep a boy for each series of beds to frighten off birds. Warm borders which contained Tomatoes in summer are well adapted for winter-sown Radishes. Under fruit trees the beds receive a little shelter, whilst the little shade caused by the naked branches does no harm. Prune Raspberry bushes leaving them about 3 feet high, and do not use stakes for them. Prune also fruit bushes of all sorts, taking care to leave a good stock of young wood and to thin out all decaying and old portions. Root out old and useless trees, and replace them with young and fruitful ones. Remove hand-lights and sashes from Cauliflowers, Lettuces, and Onions during the daytime, but replace them at night. The smallest amount of rain must be excluded from the Lettuces, as they are so apt to damp off if they become wet; therefore rather tilt up the sashes than remove them altogether. Thin and weed the plants, and stir the soil a little amongst them. Scatter some lime over all kinds of crops, more especially over those transplanted permanently, such as Cauliflowers under hand-lights. If ground is required, lift the Jerusalem Artichokes and store them; if land is not wanted, merely cut over the stalks and spread a layer of litter along the top of each drill. Dig the ground between lines of Rhubarb, and place a forkful of litter over each crown. Any Endive plants to spare plant in front of palings or walls. If the ground is required in which the general crop is growing, lift the plants, tie a piece of matting around each, and lay them in thickly in a bed for a time. Protect them from severe weather by shaking some rough litter over them. Look over Mushroom beds twice a week if bearing well, if not, once will suffice. This crop has borne remarkably well as a rule this year, owing to the winter being so dry. Frost is easily excluded by means of additional covering, but cold rains, no matter although the beds be covered with

* This department is written exclusively by amateurs distinguished for skill in various branches of gardening.

mats, find their way into the Mushrooms, destroy the spawn, and ruin the crop. Examine Seakale beds, producing Kale, and by means of the litter in the alleys and that covering the beds maintain an equable temperature. If necessary, start two other beds by filling the alleys with fermenting manure, placing a covering of the same on the surface; over that put hoops and mats, to be covered with litter if wanted. Succession beds leave exposed. Treat Rhubarb in a similar way, but give the roots more room. Take the litter off sashes put over Mint frames during the day, but replace it at night. Make another hot-bed, and lift another lot of roots, and start them to succeed those already in bearing.

Indoor Fruit and Forcing Department.—For fruiting Pines maintain a bottom-heat of 80°, and a top temperature of 70° at night, and five or ten degrees less for succession plants. Pot suckers whenever obtainable, and keep the roots of all, except those swelling fruit, pretty dry. Begin forcing Figs with a night temperature of 50°, and thoroughly moisten the soil, for, if too dry, the young fruit is sure to drop. Peaches and Nectarines set their fruit much better if fire-heat and ventilation are given night and day during the time in which they are in flower, than they otherwise would do. Syringe the trees after the fruit has fairly set, and before the bloom has expanded, but not whilst they are in flower. Begin the forcing of Cherries with a night temperature of 45°, and give fresh air freely. Strip off the loose bark from late Vine rods, and apply a coating of some insect-destroying paint. Keep the unstarted houses as cool and airy as possible, and prune any Vines not already operated on. Syringe daily until the flowers begin to open, but not after that, for plenty of atmospheric moisture may be maintained by damping the floors and walls. Introduce into heat some Strawberry plants; 45° is sufficient at first, but, if a bottom heat of fifteen degrees higher than that can be given, it would be an improvement. Continue to introduce successional roots of Rhubarb, Seakale, Asparagus, Mint, Dandelions, and Endive into the Mushroom-house or hot-beds, where a temperature of 60° is maintained.

THE KITCHEN GARDEN.

Maintain everywhere neatness and order; trench all vacant ground, turning it up in as rough a state as possible, so as to permit frost to pulverise and sweeten it, and to clear it of the larvæ of insects, which dislike exposure to hard frost. In trenching, open a thoroughly good trench and break up the ground well at the bottom of it with strong forks, allowing it to remain rough and loose. Turn into the trench all surface vegetation and rubbish, and over that lay the mould from the next trench, again well breaking up the bottom; and so proceed till all has been turned over. By well moving the soil and getting down deeper and deeper every year, good depth of soil may be secured, and thus not only will crops be supplied with abundant food, but also, in dry seasons, with moisture. With thorough drainage, deep culture, and surface stirring, luxuriant crops can be obtained from land at the first cropping. Whatever vegetable refuse may be lying about, or collected at the rubbish heap, keep close together covered with earth and salted—salt being a good deodoriser. If there is one thing more than another a gardener should feel an antipathy to it is a weed; not only do weeds impair the appearance of a garden, but their production costs a considerable amount of money, inasmuch as they rob the soil of that which should go to support profitable crops. Deep trenching is a good way of keeping them in check, and there is no doubt that by deep culture the amount of most kinds of crops might be greatly increased. Surface stirrings should also be constantly carried out on all suitable occasions. Where required, look out for a new stock of Bean and Pea sticks, and get them prepared so as to be ready for use when wanted. Seed lists, too, should be made out, in order to give the seedsmen time to get the goods put up in proper order before the busy season has arrived, and when you have the seeds home place them with the list methodically in thoroughly clean drawers or cupboards. See also that they are placed secure from the ravages of mice, and in a dry situation to prevent mildew or dampness.

Artichokes.—Still retain the mulching around the base of Globe Artichokes, and strew some straw or litter very thinly over the crowns. Lift whatever Jerusalem Artichokes are yet in the ground and store them in sheds or pits. Towards the end of the month, make another plantation in any out-of-the-way corner where their shade will not injure other plants, or where they will make a useful shelter.

Asparagus.—If last month's directions have been attended to, this crop will require no attention till next month; but if not, apply a good mulching of manure and seaweed, if obtainable, to the beds.

Beans.—Earth up whatever Beans have appeared above the surface soil, and make another sowing if necessary on a warm border, this time including some Long-pods.

Broccoli.—Take up such plants as are "turning in" with good

balls, and keep them in sheds or cellars until they perfect their heads, providing the weather be severe, but, in the event of fair weather, leave them undisturbed in the ground and break a leaf over the curd to protect it from sunshine. Clear away stumps of sprouting Broccoli from under the trees as soon as they yield their crop.

Cabbage.—Plant out according to demand from the store beds of the autumn sowings, and sow a sprinkling of some small early sort if necessary, either in a frame or in a warm border.

Cardoons.—Rather than encumber the ground any longer with these, lift and store them amongst clean sand in a shed, where they will become blanched, and be always ready for use. Occasionally examine them to remove any decaying leaves.

Carrots.—Examine the stored roots and remove all decaying ones, from which cut away the decaying portion, and use the wholesome part at once, either for culinary or farm purposes. Sow a few Early Horn Carrot seeds on a slight bottom-heat and on an open dry border, if free from frost; and have a sharp look-out for damping, shrinking, canker, mildew, and slugs, and dredge the plants occasionally with wood-ashes and dry dust.

Cauliflowers.—Sow some seeds in frames in a very gentle heat. Freely expose on every favourable opportunity those wintered in frames, and tilt up the sashes at back and front during rainy weather. About the end of the month plant them out, nine under a hand-glass, or in rows in borders, or warm sheltered quarters.

Celery.—Sow some seeds in pans of light rich soil in gently heated frames, and prick out the seedlings into boxes or large pans as soon as they can be handled. In case of hard frost, protect the Celery in ridges with litter or Fern, to permit of its easy access during all weather.

Endive.—Maintain a good supply of nearly full-grown plants lifted from the open air, in pits or frames where the temperature ranges about 50°, and where they can be darkened at pleasure.

Horse Radish.—Lift the old plantations of this and store the useful roots in sand in a pit or cellar, but every particle of the roots, small and large, should be removed from the soil, as they will only cause future annoyance by growing again if left. Make fresh plantations in deeply trenched ground.

Lettuces.—Sow some seeds of the white and green Paris Cos Lettuces in frames, and the Bath Cos in rows where they are permanently to remain, because they are somewhat liable to run to seed when transplanted. Draw the lights entirely off the frames containing late autumn sowings in favourable weather; but replace them in the event of frost, or cold rains or snow.

Onions.—If a frame can be spared for the purpose, sow some Tripoli, or white silver-skinned, Onions for salading, as they will come in nice and useful six weeks sooner than the main outdoor sowings; and what are not required for this purpose can be used for transplanting purposes, when they will produce larger bulbs by autumn than the ordinary spring sowings.

Parsley.—Keep this crop clean from drifting leaves, and protect a few plants with hoops and mats in case of frost. By sowing some seeds in a dry and warm border, a good supply of young Parsley can be had a month sooner than from the ordinary spring sowings.

Peas.—Draw some earth to those that are a little above ground, and also stake them in good time, not only for the support contributed thereby, but also for the shelter the stakes afford. Make a successional sowing, either in a border or sheltered quarter, keeping the rows about 4 or 6 feet apart, in order to permit of intercropping with Cauliflower or Spinach.

Radishes.—Sow some seeds amongst Potatoes in frames, or independently by themselves. Sow, also, in quarters or borders, and mulch them over with litter till the seeds germinate.

Rhubarb.—In fine weather, and when the ground is in a good workable condition, lift and divide some of the roots, and transplant them in deeply worked soil in rows 3 feet apart, and the plants 2 feet asunder. Place a large forkful of rank litter over the crowns of the old plants in order that the leaf-stalks may come up under it cleaner and more tender than they would if left quite exposed.

Seakale.—Those that prefer earthing up Seakale to blanch in preference to covering it with pots, or a framework of wood, and covering with leaves, should do so at once. Under any circumstances it is now time to cover up this crop.

Spinach.—In frosty weather strew some rank litter over the best rows of this crop, and in fine weather remove it and loosen the surface soil. About the end of the month sow some seeds of the round-leaved sort between rows of Peas, or in any other convenient but sheltered position where the ground is not too wet and cold.

Turnips.—Sow some early Turnips on a warm border, or between rows of Peas. Do not permit useless roots to occupy the ground at this season; rather lift all. Preserve the good in pits, and throw away the bad, and have the ground roughly dug, and in readiness for another crop.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES ON LANDSCAPE GARDENING.

By JAMES M'NAB, Royal Botanic Gardens, Edinburgh.

PERHAPS no subject is more interesting or more deserving of general attention than that of landscape effects produced by the aid of landscape gardening, and it is one upon which it is often impossible to get two individuals to form the same opinion. If the surface of the land to be operated on is varied and undulated, it will greatly assist the operator whose taste and skill are to be brought to bear upon it. To be successful in landscape gardening, one must have the eye of an artist, and the pencil of an artist, as well as a strong natural feeling for the beautiful, and even with these requisites much that may be done will not, for many years, realise the ultimate effect which a landscape gardener is anxious to impart to his subject. The designing of a picture on canvas, so as to have it well balanced and pleasing to the eye, requires from the artist himself much thought and consideration; and, if found to be faulty, it is easily put right by a few touches from the brush. In regular geometrical gardening, plans can be made and carried out to a nicety, even for avenues and carriage drives, but, as regards landscape gardening, in its full and true acceptation, no detailed plan can be executed on paper. The arrangement and disposition of trees and shrubs, for effects suitable for the undulating nature of the land, must emanate from the fertile brain of the qualified man into whose hands such works are entrusted. After all the work has been done, and the trees properly planted and grouped, it often takes years to produce the effects intended. It is not always the original designer that makes landscape gardening tell in every detail. His duty is to plant freely, both singly and in groups, using as many varieties as possible, so as ultimately to produce effective tints for spring, summer, and autumn, for which purpose numerous sorts of trees, now exist in cultivation. Care should also be taken to secure a diversity in the form of trees, such as the upright and weeping kinds, and those with spreading branches, always keeping in view a well selected proportion for flowers and foliage. Without these requisites landscape gardening is apt to be tame. To have all the varieties here stated planted promiscuously through each other, would be as great a mistake. The successful grouping of such trees can only be effectually done on a broad scale, and on ground more or less undulating.

Suburban villa residences now occupy much of the time of the landscape gardener. For such limited space it often requires the utmost nicety in the arrangement, so as to give them a diversity of surface, as well as a feeling of extent. Some villas stand on level ground, are walled in, and command no views; for such places a simple form of laying out can easily be arranged by having, in suitable places, raised belts of evergreens, for the purpose of giving extent. When the ground is undulating and limited it requires very great care, when planting, to secure the distant landscape effects, which such situations were originally destined to command, without exposing such residences more than is necessary. In some cases such villas are built in situations so as to command views, and are planted up all round, under the plea of shelter. These shelter trees do not for many years interrupt the landscape effect; gradually, however, and by almost imperceptible degrees, they shut out the views. This planting up is so far correct, and what, under ordinary circumstances, may be looked for, provided due care be afterwards taken to open up vistas by the removal or branching of certain trees, not all at once, but by degrees. In some situations the full scope of landscape gardening can only be successfully carried out after the trees in such places come to be matured, and it is at this stage that the services of the practical landscape gardener are most required. I have frequently had occasion to point out to proprietors the advantage of these partial clearances, and it is often gratifying to see, that when one little picture is produced in a frame of foliage, either by the cutting off of certain branches, or the removal of a tree altogether, the desire generally increases to

multiply such views. It is possible, however, without proper guidance, to carry this too far, as, in some instances, fine trees are ruthlessly sacrificed for the landscape effects produced by their removal. Of course, such thinnings must be carefully and judiciously done, so as not to injure the outline of the picture intended to be produced, nor endanger the shelter of the place. For the smaller villas it is not absolutely necessary that they present a picturesque effect from the neighbouring country; but it is different with a nobleman's residence, where it ought to be a primary object to make such places tell from as many points as possible, groups of trees, as well as single specimens, being tastefully arranged around them.

On large domains apparent errors are frequently seen, or, if not errors, they are effects far from pleasing to the eye. A large old mansion, standing on level ground, having a long straight road or avenue in front, is very often to be met with, and is sometimes suited for certain styles of architecture. With all modern buildings, such straight roads ought to be avoided, and, more particularly, if the land is in the least degree undulating; such, however, is sometimes done, but whether from the wish of the architect or the proprietor, it is difficult to say. When a new house is placed in the neighbourhood of old and well-shaped trees, it may be difficult to get proper clearances made for a suitable approach without the sacrifice of some fine specimens, but such limited feelings should not be allowed to exist. If £100,000 has been laid out on a mansion, nothing should stand in the way of making the approach, and everything else around it, as perfect as possible. In the formation of large parks and pleasure-grounds round large mansions, and even with places of moderate extent, it would be desirable if the architect and landscape gardener could go hand in hand in the details of the outside work, particularly in the immediate neighbourhood of the house, instead of being antagonistic, as frequently happens: a harmonious feeling would often save a great deal of after-work, and consequent expense. I am not quite certain if the modern style of terraces and geometrical flower-gardens, in the immediate vicinity of a large residence, is altogether in good taste. A large expanse of Grass, and good grouping of trees and shrubs, have always appeared to me to give to large mansions a degree of stateliness which they cannot have by any style of geometrical flower-gardening placed immediately under the windows; to say nothing of the jar of the mowing-machine continually going on during early morning, and which often proves a great source of complaint to gardeners. But such terraced gardens, from their extent, cannot be made to look well without constant machine-work.

On large and level policy grounds, also in public parks, good effects are produced by the formation of large sheets of water, of a somewhat irregular form, so as to give the grounds a greater appearance of extent; such a sheet of water lying in sight of the chief windows, has, to me, a more pleasing effect than many of the modern flower-garden departments, placed immediately before the house. The soil round such artificial lakes should be placed in irregular waving mounds around the margin, but chiefly on one side; and these raised grounds planted over with trees and evergreen shrubs, having on the flat Grassy spaces a sprinkling of the various species of *Yucca*, *Cordyline*, *Phormium tenax*, *Gynerium argenteum*, *Arundo conspicua*, also clumps of evergreens and deciduous flowering shrubs and perennial herbaceous plants. If rock-stones are abundant in the neighbourhood, a shelving group of them here and there, close to the water edge, gives a pleasing effect, and, if narrowed in certain points, rustic bridges become telling objects.

In villa gardens, and moderate-sized mansions, geometrical flower gardens, or clumps placed near the house, are by no means objectionable. Such residences being often limited in extent, prevents them being put elsewhere. The flower plots, however, should not all be filled up with bedding-out plants. Three or four may be occupied with scarlet *Geraniums* or any other favourite summer-flowering plant, these to be removed in autumn, and their places filled up with the bulbs of *Hyacinths* or *Tulips*, for spring effect. The major portion of the clumps should be filled with peat soil, and planted with hardy *Heaths*,* or dwarf free-flowering American plants, or

* See article on hardy *Heaths* in THE GARDEN, 21st December, 1872.

others requiring bog earth, of which a large variety now exists in nursery collections, and some kinds of which will be found flowering so as to give a succession during the whole year. If the clumps are raised and arranged with rock-work sides, Mossy and other Saxifrages, Sedums, and Sempervivums, can be grown without much trouble. By this arrangement, villa-garden clumps would have a clothed appearance all the year round, which is not generally the case during the autumn, winter, and spring months, unless temporarily filled with coloured Kales, Acubas, and variegated Hollies, to be removed when the summer bedding plants are to be put in. This changing style of gardening is often attended with much trouble, for which the three or four months of bloom will scarcely compensate.

THE SPECIES OF TULIPS.

As much interest is now taken in the cultivation of bulbous plants, we believe that the following slightly abridged translation of an article by Dr. Regel, of the Botanic Gardens, St. Petersburg, which appeared in a recent number of the *Gartenflora*, will be acceptable to many of our readers. Very few persons, we think, are aware that there are so many distinct species of Tulip as are here enumerated, the greater number of them being, up to the present, quite unknown in our gardens. Many of them, however, are worthy of introduction, and we shall be very pleased if our notice of Dr. Regel's "Synopsis" proves the means of directing the attention of our cultivators to even the one very beautiful species, *T. Greigi*, the acquisition of which would form a very important addition to our list of fine flowering plants. Every lover of hardy bulbs is, of course, familiar with the numerous and beautiful varieties of a few species that adorn our gardens in spring. The species to which we now call attention, while for the most part highly ornamental, may, in time, give rise to new races as important as those we already possess, in the various forms of *T. Gesneriana* and the bedding Tulips.

Synopsis of the Species of Tulips.

A. Inner perianth-segments and the stamens bearded at the base.

* Leaves linear, or linear-lance-shaped, or narrowly-lance-shaped.

a. Bulb-scales thickly bearded on the inside towards the top, and sometimes at the base.

1. *Tulipa sylvestris*.—Flowers, yellow; stamens, covered at the base with woolly hairs. Leaves, narrowly-lance-shaped or linear-lance-shaped, and somewhat flat. Anthers, usually linear, and about as long as the stamens. Perianth-segments, nearly 2 inches long. Flower-stalk from 8 to 16 inches high. Native of central and southern Europe.

a. *T. s. var. Biebersteiniana*.—Flowers, yellow, the outside or back of the perianth-segments being greenish or purplish; in other respects like those of the type, but smaller. Stamens, covered with weak hairs at the base. Flower-stem bearing one flower, seldom two. Native of South Russia, the Crimea, Podolia, Greece, the Caucasus, and Turkestan.

b. *T. s. var. tricolor*.—Flowers, white on the inside and yellow at the base, greenish or dull purple on the outside. Stamens, covered with weak hairs at the base. Flower-stem, from 3½ to 12 inches high. Leaves, varying from linear to linear-lance-shaped, upright or reflexed, flat or undulating, as long as, or longer than, the flower-stem. Anthers longish or elliptical, twice or thrice as short as the stamens. This is a purely Russian species, its distribution extending from the Steppes of the Volga and the Caspian Sea to the Ural and Altai Mountains, Soongorie, Ili-gebiet, and Turkestan.

c. *T. s. var. cretica*.—A dwarf species, with rose-coloured or pale rosy flowers. Stamens covered with weak hairs at the base. Flower-stem, only from 2½ to 4 inches high, leafy, one-flowered, shorter than the leaves. Leaves, like those of the preceding species, varying in shape, direction, &c. Native of the loftier mountains of Crete, and the Caucasus.

d. *T. s. var. pulchella*.—Another dwarf species, from 3½ to 5 inches high, with purplish-red flowers, marked with purplish-black spots. The one-flowered stem bears three or four linear-lance-shaped erect or reflexed leaves, which generally over-top the flowers. Found at Kotschy, in the Taurus Mountains, Asia Minor.

e. *T. s. var. Orphanidea*.—This species differs from the type only in having flowers of a saffron colour, shaded with purple. Native of the mountains of Greece.

f. *T. s. var. turkestanica*.—This looks very like a small-leaved dwarf variety of *T. s. Biebersteiniana*, but the bulb-scales are covered

with weaker and longer hairs on the inside at the top, all the other parts being quite smooth. Rather common in Turkestan.

b. Bulb-scales covered on the whole of the inside with a cobweb-like pubescence.

2. *Tulipa biflora*.—Plants of this species are sometimes dwarf, and sometimes grow to 1½ feet high. The flower-stem is smooth, and generally bears two flowers (seldom one, or more than two). The flowers are at first bell-shaped, but, afterwards, the segments stand apart; the colour is white or bright yellow on the inside, the outside being greenish or reddish. Leaves, linear, or narrowly linear-lance-shaped, and usually reflexed (seldom erect). This species is very like *T. s. tricolor*, and is chiefly distinguished from it by mostly bearing its flowers in pairs, and by the woolly inside surface of its bulb-scales. Native of South Russia, the Steppes of the Caspian, Soongorie, and Aral, Turkestan, the Caucasus, and Persia.

T. b. var. Bukseana.—Flowers, bright yellow, reddish on the outside.

c. Bulb-scales smooth on the inside.

3. *Tulipa Celsiana*, Redoute.—This species is entirely smooth, and, in its growth and characteristics, resembles *T. s. Biebersteiniana*. The flowers are yellow, edged with red or white, and are red on the outside. Its distinctive peculiarity is that the inner surface of the bulb-scales is quite smooth. Native of South-western Europe.

** Lower leaves oval, or elongated oval.

4. *Tulipa saxatilis*, Sieber.—Sieber collected two different kinds of Tulip at Cape Maleca, in Crete, and distributed both under the name of *T. saxatilis*. Of these, the dwarfer, small-leaved kind, which various authors have described under the name of *T. saxatilis*, should properly be referred to *T. s. Biebersteiniana*. The other approaches more nearly to the typical form of *T. sylvestris*, but is distinguished from it by its considerably broader leaves, by its stamens being brown at the base and covered with woolly hairs, and by its more deeply divided trifid stigma. We have retained the name of *T. saxatilis*, in the case of the latter form, as we have not yet seen the bulbs, and as the yellowish flowers are marked with a darker colour at the base. It is possible, however, that it may, hereafter, have to be referred to *T. sylvestris*.

B. Inner perianth-segments and the stamens smooth at the base, or, the latter, in one species (*T. Sibthorpiana*) furnished with deciduous weak hairs, and the former in one species (*T. Soongdiana*) ciliated at the base.

* Perianth-segments, marked at the base with a blackish or blackish-blue spot.

a. Perianth-segments, oval or elliptical, lance-shaped, blunt or shortly pointed.

†. Flower-stem smooth.

a. a. Lower leaves oval, or oval-lance-shaped, or lance-shaped, or linear-lance-shaped; upper leaves narrower.

5. *Tulipa Oculi-solis*.—Bulb-scales tomentose on the inner surface. Flowers, funnel-shaped; segments, shortly pointed and covered with indistinct weak hairs at the point; colour, scarlet, paler on the outside; inside of each division marked at the base with a large, longish, oval, blackish spot, surrounded with a yellow zone. Native of France, Switzerland, Italy, and the east.

a. *T. O.-s. var. maleolens*.—Flowers, bell-shaped, purple (seldom streaked with yellow), the outer segments shortly pointed, the inner ones blunt; all slightly bearded on the points, each segment having a round dark yellow spot at the base. Lower leaves lance-shaped, generally ciliated at the margin.

b. *T. O.-s. var. praeox*.—Flowers, bell-shaped; segments, all shortly pointed and bearded at the points; colour, orange-red or purple. In all other respects like the preceding variety.

c. *T. O.-s. var. Strangwaysi*.—Flowers, oval bell-shaped; segments all blunt; colour purple, with an indistinct yellow spot at the base of each segment. Leaves lance-shaped.

6. *Tulipa Didieri*, Jord.—Bulb-scales thickly bearded on the inner surface towards the top. Flowers purple or reddish-yellow or yellow; segments shortly pointed, and covered with indistinct short hairs at the points. Stigma large, trifid, exceeding the ovary in diameter. Leaves bluish-green, mostly ciliated on the margin. It approaches very nearly to the form of the preceding species. Native of France and Persia.

7. *Tulipa Borszczowi*, Rgl.—Bulb-scales covered thickly on the inner surface with long, thin, brown, silky hairs. Flowers yellow or orange-red, with a dark blue spot at the base of each segment. Segments oboval-wedge-shaped, blunt or abruptly pointed. Stigma slightly trifid. Flower-stem from 8 to 16 inches high, one-flowered, bearing three or four leaves, and covered as far as the middle, or higher, with the withered leaf-sheaths of the preceding year. Leaves dark green, very much undulated, and edged

with a transparent cartilaginous margin. Native of the Aral Steppes and Turkestan.

8. Tulipa Julia, C. Koch.—Bulb-scales, as in the preceding species. Flowers, broadly bell-shaped; segments, oboval-wedge-shaped, blunt, or rounded, or abruptly short-pointed; colour, purple, with a blackish-blue spot at the base of each segment, often marked with several darker coloured dots; stigma, slightly trifid; flower-stem, from 2½ to 4 inches high, one-flowered, and bearing three or four leaves; leaves, lance-shaped, or narrowly lance-shaped, mostly undulated; upper leaves narrower; plant entirely smooth. Native of the Caucasus and Turkestan.

b. b. *Leaves linear.*

9. Tulipa Boissieri, Rgl.—Flowers, purple; outer segments, oval, shortly pointed; inner ones, oboval-wedge-shaped, margined in front with small points; each segment marked at the base with a dark-blue spot; flower-stem, one-flowered, bearing three leaves; leaves erect, ciliated, longer than the flower-stem. Native of Palestine.

†† *Flower-stalk more or less hairy.*

10. Tulipa Greigi, Rgl.—Bulb-scales, bearded on the inner surface at the top. Flowers, broadly bell-shaped, scarlet, or purple, or, more rarely, yellow; segments, reflexed, ovate, or obovate wedge-shaped, shortly pointed, or obtuse, or apiculate from the rounded apex, each segment marked at the base with an oblong blackish spot; flower-stem from 2½ to 8 inches high, one-flowered, bearing three or four leaves. Lower leaves, ovate or ovate lance-shaped; upper ones, narrower, all smooth, undulated, edged with a cartilaginous margin, and marked thickly with oblong tawny spots. A very handsome species. Native of Turkestan.

b. *Perianth-segments oval, the outer ones obovate-ligulate, pointed.*

11. Tulipa Euanthiæ, Orph.—Bulb-scales, thickly bearded on the inner surface. Flowers, purple; segments, oval, with a long blackish spot at the base; the inner ones shortly pointed. Flower-stem, covered with short hairs, one-flowered, bearing three leaves. Lower leaves, oval-lance-shaped, or lance-shaped, all undulated and scarcely margined. Native of Greece.

c. *Perianth-segments lance-shaped, the outer ones narrowed into a point.*

12. Tulipa aleppensis, Boiss.—Flowers, purple; segments, narrowed at the sides, and mostly ending in a point, marked at the base with a longish, linear, blackish spot. Flower-stalk, smooth; stem, one-flowered, bearing three or four leaves; leaves, flat, not margined, the lower ones lance-shaped, or narrowly lance-shaped. Native of Syria, near Aleppo.

13. Tulipa bæotica, Boiss. and Heldr.—This species very much resembles the preceding, but is distinguished from it by its undulated leaves, its flower-stalk covered with short hairs, and its perianth-segments bearded in front. Native of Greece.

* * *Perianth-segments, without any blackish spot at the base.*

a. *Perianth-segments, blunt or shortly pointed.*

† *Flower-stalk, smooth. Flowers, erect.*

a. a. *Leaves, not margined; the lower ones oval, or oval lance-shaped, or lance-shaped; upper leaves, narrower.*

o. *Bulb-scales, smooth on the inner surface.*

14. Tulipa Gesneriana, L.—This species is the parent of the well-known late-flowering garden Tulips. It appears in an immense variety of forms, with red, yellow, and variegated flowers, single and double; and with slashed flower-segments, in the so-called Parrot Tulips. Native of Southern Europe and the East.

o. o. *Bulb-scales thickly bearded on the inner surface towards the top.*

15. Tulipa Schrenki, Rgl.—Flowers, broadly bell-shaped, yellow, or, more frequently, purple, somewhat smaller than those of the common Tulip; segments, blunt or shortly pointed, slightly bearded at the apex. Stem, 9 or 10 inches high, one-flowered, bearing three or four undulated leaves. Plant entirely smooth. Native of Soongorei, Ili-Flussgebiet, and Turkestan.

b. b. *Leaves, with a transparent cartilaginous margin; lower leaves, elongated lance-shaped; upper leaves, narrower.*

16. Tulipa Lehmanniana, Merckl.—Flowers, bell-shaped, yellow; segments, longish-oval, pointed or shortly so. Stem, one-flowered, bearing four leaves; leaves very much undulated or curled, and reflexed; bulb unknown. This species is closely allied to the preceding one. Native of the Steppes of Bokhara.

c. c. *Leaves not margined; lower leaves, linear lance-shaped; upper leaves, linear; sometimes all the leaves linear.*

17. Tulipa Soogdiana, Bunge.—Bulb-scales, densely covered with hairs on the inner surface. Flowers, broadly bell-shaped, apparently yellowish; segments, elongated-oval, blunt or pointed, very shortly bearded in front; inner segments ciliated at the base. Stem, from 3 to 5 inches high, one-flowered, bearing two leaves; leaves reflexed, flat at the margin. This species is nearly allied to

T. biflora, but is distinguished from it by the stamens being quite smooth at the base. Native of the Steppes of Bokhara.

18. Tulipa armena, Boiss.—Bulb-scales, thickly set on the inner surface with long stiff hairs. Flowers, yellow; segments, oboval, blunt, or the outer ones with a small point; stem, 3 to 4 inches high, one-flowered, usually bearing four leaves; leaves reflexed, undulated at the margin. Native of Armenia.

19. Tulipa Clusiana, Vent.—Bulb-scales, tomentose on the inner surface. Flowers, almost funnel-shaped; segments, lance-shaped, narrowed towards the base; outer ones pointed, white on the inside, and violet-coloured on the outside, near the point; inner segments, blunt, white. Stem, from 8 to 16 inches high, one-flowered, bearing from three to five leaves. Leaves, erect, far apart, flat at the margin. Plant entirely smooth. Native of South Europe, North Africa, and the East.

a. *T. Cl. var. stellata.*—This variety has the outer segments violet-coloured on the point only.

20. Tulipa montana, Lindl.—Bulb-scales, tomentose on the inner surface. Flowers, purple, bell-shaped, or broadly so; segments, all oval, pointed, and yellowish at the base. Stem, 9 inches high, or shorter, one-flowered, bearing three or four leaves. Leaves, reflexed, far apart, undulated at the margin. Plant entirely smooth. Native of Persia.

a. *T. m. var. maculata.*—This variety has the purple flower-segments marked with a small blackish spot at the base inside; outer segments, shortly pointed; inner ones, blunt.

b. *T. m. var. chrysantha.*—Flowers, of a golden-yellow colour; outer segments, pointed; inner ones, blunt.

†† *Flower-stalk, smooth; flowers, nodding.*

21. Tulipa Sibthorpiana, Sm.—Up to the present, this species is only known from Sibthorp's drawing, and, perhaps, should not be referred to the genus *Tulipa* at all, but to the genus *Orithyia*. Flowers, bell-shaped, yellow; segments, longish-spathulate, bluntish; stamens, covered with hairs their entire length. Stem, one-flowered, bearing two leaves. Leaves, erect, flat, not margined; the lower ones, elliptical-lance-shaped. Native of Greece.

††† *Flower-stalk, covered with short hairs.*

22. Tulipa suaveolens, Roth.—Outer bulb-scales, covered with hairs on the inner surface; inner scales, quite smooth. Flowers, broadly bell-shaped, erect, generally purple (seldom entirely yellow), with a golden-yellow margin round each of the segments, which vary in shape from oboval to lance-shaped, and are blunt, or shortly pointed. Stem, from 9 to 12 inches high, one-flowered, bearing from three to six leaves. Leaves, erect, not margined, rather flat, the lower ones elliptical-lance-shaped. Native of S. Europe. In gardens it occurs with both double and single flowers, and with stems of various heights.

23. Tulipa strangulata, Reboul.—Flowers, pitcher-shaped and of various colours, yellow, purple, &c. Leaves, smooth or hairy, not margined. In all other respects similar to *T. suaveolens*. This and the preceding species are the parents of the numerous varieties of the early or forcing Tulips of our gardens, such as *Duc Van Thol*, &c. Native of Italy.

24. Tulipa altaica, Pall.—Bulb-scales, thickly covered with hairs on the inner surface. Flowers, broadly bell-shaped, yellow inside, greenish or light purple outside; segments, elongated-elliptical, pointed, or rounded, with a small projecting point. Stem, from 9 to 12 inches high, one-flowered, bearing two or three leaves. Leaves, bluish-green, erect or reflexed, covered with short hairs or smooth, curled at the edges, and surrounded with a transparent cartilaginous margin; the lower leaves longish-oval, or longish-lance-shaped. Native of the Steppes of Soongorei, Ili-gebiet, and Turkestan.

b. *Perianth-segments elongated into a long tail-like point.*

25. Tulipa turcica, Roth.—Bulb-scales, covered on the inner surface with long, brown, shaggy, silky hairs. Flowers, bell-shaped, erect, light purple, white, or yellowish; segments, narrowly lance-shaped, ending in a long bearded point. Flower-stalk, smooth. Stem, from 1 to 1½ feet high, one-flowered, bearing from three to five leaves. Leaves, linear-lance-shaped, erect, rather flat, not margined. Native of Persia and Turkey.

a. *T. t. var. media.*—The flowers of this variety are of a deep scarlet, chequered on the outside with white; the segments also are not bearded at the point.

26. Tulipa undulatifolia, Boiss.—Flowers, broadly bell-shaped; segments, oval, long-pointed, with short hairs on the point and also on the flower-stalk. Stem, one-flowered, bearing several leaves. Leaves, lance-shaped, reflexed, undulated and curled at the margin. Native of Asia Minor, near Smyrna. I have not seen this plant either in a dried or living state; the description here given is that of Boissier, *Diagn. ser. 1, fasc. V. page 57.*

NOTES OF THE WEEK.

— WINTER Pears are behaving curiously this season. Kinds on which the Covent Garden fruiterers usually depend in March are not only ripe, but, in too many cases, rotten now. This is generally true of all winter Pears, both English and French. There has been much loss, and, it is supposed, there will be a great scarcity of Pears by-and-bye. Does the mild season help to explain this?

— At a meeting, held the other day, of the Botanical Society of Edinburgh, Mr. M'Nab laid on the table 138 species of flowers picked in the Botanic Garden on the 1st of January this year. Of these thirty-five might, he said, be considered as winter and spring flowers, while the remaining 103 might be looked upon as summer and autumn plants still flowering.

— THE Early Mount Lebanon Iris (*I. Histrio*), a near relative of *I. reticulata*, is just now in flower on a border in the herbaceous grounds at Kew. It bears beautiful blue flowers, spotted with deep purple, its fresh flowers just peeping through the surface of the soil. It is new to our gardens, and deserves general cultivation. It differs from *I. reticulata* in its smaller size, and much fewer, shorter, and broader leaves, and differently-shaped inner perianth-segments.

— ONE of the prettiest bouquet combinations now in Covent Garden Market consists of the pure white flowers of Camellias, Azaleas, Bouvardias, Lily of the Valley, and Tea-scented Roses, spotted here and there with blooms of the bright blue *Nemophila*. This common blue flower, now produced in hothouses, has quite as good an effect set in white ground-work as a blue *Cineraria*.

— WE have just received from Messrs. Hooper, of Covent Garden, some tasteful wreaths of artificial foliage and flowers made of metal, and carefully coloured after nature. It is considered that they will be much more suitable for the ornamentation of tombs than the wreaths of gaily coloured Immortelles, now so generally used for that purpose, as they will be more durable. Wreaths of this kind will also be found useful on festive occasions, for wall decorations not too near the eye.

— WE this week give an illustration of the seed-vessels of the Gladwin (*Iris foetidissima*), sometimes, also, called the Roast-beef plant, accompanied with a description by Miss Hassard. It is only this season that this very old plant has come into use for indoor decoration. We have long admired it for the sake of its brilliant seeds in winter, so useful in the wild garden. It may be well to mention that the variegated form of this is one of the most popular and most effective plants grown in rooms on the Continent. It thrives in the dry air of rooms; its white variegation is effective by artificial light, and it is sufficiently graceful in habit to associate well with the various plants used for room-decoration.

— AT Nassau, in the Bahamas, an establishment for canning Pine-apples has been put into operation this season, at a cost of £200,000. Six hundred hands are employed in preparing and packing the fruit. A million Pine-apples have been purchased this season, which were grown upon these islands, and were, therefore, procured in their greatest state of perfection, and over a million cans have been packed. The Pine-apples are purchased at from 18 to 40 cents a dozen, and the cans cost on importation thither 4 dollars 50 cents a dozen.

— IN a recent number of the *Gartenflora*, Dr. Regel describes a new species of Tulip, from Turkestan, which flowered last year in the Botanic Gardens at St. Petersburg, and which, he says, is so beautiful that he considers it the Queen of Tulips. The flowers are of a brilliant scarlet (in some varieties, purple, or, more rarely, yellow), from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long, and from 1 to $1\frac{1}{2}$ inches broad, broadly bell-shaped, the points of the divisions of the corolla being much reflected. Flower-stalk from $2\frac{1}{2}$ to 8 inches high. The leaves are thickly covered with oblong tawny spots, reminding one of the leaves of *Orchis maculata*. A well executed coloured figure accompanies the description of this Tulip, which Dr. Regel has named *Tulipa Greigi*, in honour of Mr. S. A. Greig, the President of the Russian Imperial Horticultural Society.

— AMONG a number of rare plants collected by Herr T. von Heldreich in the course of a botanical excursion in Attica last year, was a very handsome species of Horned Poppy (*Glaucium*), which he found growing on the rubbish-heaps at the lead mines of Laurium, and named *Glaucium Serpieri*, in honour of Herr J. B. Serpieri, the founder of the mines. This Poppy is finely figured in a coloured plate in a late number of the *Gartenflora*, and described in an accompanying letter from Herr von Heldreich, in which it is stated that it grows from 1 to 3 feet high, and bears golden or crocus-yellow flowers (larger than those of the common *Glaucium luteum*), with a dark violet spot at the base of each petal. The plants grew in great abundance on the rubbish-heaps, and Herr von Heldreich was so fortunate as to discover amongst them a variety bearing very double flowers of the same deep golden colour (but without the violet spots),

and resembling in appearance the flowers of the double-flowered *Ranunculus asiaticus*, only of larger size.

— A MEETING of Fellows of the Royal Horticultural Society, was held on the 8th inst., to consider the question of voting by proxy, but was terminated without any definite result being arrived at.

— WE have received a new edition of the "Treasury of Botany," the best and most complete book of its class, and one to which we shall allude more fully hereafter. It is edited by Mr. Thomas Moore, a sufficient guarantee of its trustworthiness.

— A LADY correspondent tells *Moore's Rural* that for many years past she has had ripe Tomatoes in February—growing them in her kitchen from seed sown in midsummer in large boxes. She trains them on trellises, and they are ornamental as well as a pleasure to the palate.

— It is proposed to erect a winter garden at Torquay, and Mr. Eyles and Mr. Rendle have been consulted in reference to the project. A committee has been appointed to furnish a definite statement as to cost, and Mr. Eyles has been instructed to prepare three plans, to show what can be done for the respective sums of £10,000, £20,000, and £30,000.

— UNDER the name of *Eremurus robustus*, Dr. Regel describes and figures, in a recent number of the *Gartenflora*, a very handsome hardy Liliaceous plant which has flowered in the open air in the Botanic Gardens at St. Petersburg and Moscow. From a loose crown of narrow ribbon-like leaves, about 2 feet long, it sends up a leafless flower-stem to a height of about $4\frac{1}{2}$ feet, bearing on its summit a dense spike of rosy flowers, 2 feet or more in length, each of the flowers being nearly 2 inches in diameter. This very charming plant, which was discovered in Turkestan, is worthy of a place in the best collections.

— A COMMITTEE, consisting of Lord Cathcart, Mr. Whitehead, Mr. Turner, Mr. Wakefield, Mr. Brandreth Gibbs, Mr. J. Bowen-Jones, Mr. Carruthers, F.L.S., and Mr. J. Algernon Clarke, appointed by the Royal Agricultural Society to carry into effect the suggestions of the judges of the Potato-disease essays, held a meeting this week at Hanover Square. They will recommend the council to offer three prizes of £100 each for disease-proof Potatoes. Competitors will probably be required to send in one ton of each variety by the middle of February. Each sample will be distributed among growers in many different parts of England, Wales, Scotland, and Ireland; and the produce of Potatoes which resist disease during the first year's trial will be tested for two years longer. With a view of encouraging the production of new varieties, handsome prizes are to be offered also for disease-proof sorts raised from Potato-plums, to enter into competition in the spring of 1879. The terms and conditions will be decided upon at the next meeting of the council.

— THE finest kitchen garden in France, is that of Versailles, which belongs to the State, and brings in a yearly revenue, taking good and bad years together, of about 20,000 francs, the produce of the sale of the fruit and vegetables raised in this useful work of La Quintinye, gardener to Louis XIV. The Assembly has determined to apply this valuable property to the formation of a model market-garden and school of horticulture. The details of the institution are not yet arranged, but it is presumed that it will be self-supporting, and that it will render valuable assistance in the development of horticultural science in France. The industry, to the growth of which this school will, doubtless, largely contribute, is greatly on the increase in France. Fifteen or twenty years ago the exports of French fruit and vegetables represented a money value of from eight to ten millions. That figure has now increased to thirty-five or forty millions, a progression which would be become even more rapid if market-gardening in France were uniformly conducted on sound principles of horticulture, such as it will be the business of the proposed institution to exemplify and popularise.

— THE mildness of the present season, though unusual, bears no comparison to that of some winters "long gone by." In 1172, the temperature was so high that leaves came out on the trees in January, and birds hatched their broods in February. In 1289, the winter was equally mild, and the maidens of Cologne wore wreaths of Violets and Corn-flowers at Christmas and on Twelfth Day. In 1421, the trees flowered in the month of March, and the Vines in the month of April. Cherries ripened in the same month, and Grapes appeared in May. In 1572, the trees were covered with leaves in January, and the birds hatched their young in February, as in 1172; in 1585, the same thing was repeated, and it is added, that the Corn was in the ear at Easter. There was in France neither snow nor frost throughout the winters of 1538, 1607, 1609, 1617, and 1659; finally, in 1662, even in the north of Germany, the stoves were not lighted, and trees flowered in February. Coming to later dates, the winter of 1846-47, when it thundered at Paris on the 28th of January, and that of 1866, the year of the great inundation of the Seine, may be mentioned as exceptionally mild. In the woodbanks Violets and Primroses are in full bloom in many parts of the country.

THE INDOOR GARDEN.

ORIGIN OF DOUBLE ZONAL PELARGONIUMS.

I HAVE read with interest in THE GARDEN of December 27th Mr. Peter Grieve's article on Zonal Pelargoniums. He therein regrets being unable to give the name of the originator, or the precise date of the introduction, of the double-flowering varieties. As, in my opinion, it is very interesting in the history of floriculture that the date of the introduction of a new plant or new variety should be preserved, I seize this opportunity of informing English horticulturists of the origin of the first double Zonal Pelargonium. M. Henri Lecoq, director of the Botanical Gardens of Clermont-Ferrand, department of Puy de Dôme, France, wrote to me on the 1st of March, 1867, as follows:—"The first double Zonal Pelargonium has been cultivated here in my garden and many others, under the name of Triomphe de Gergovia, for several years (I cannot say how many), and nobody paid attention to it, thinking, like myself, that it was generally known." Seeds obtained from it were sown by M. Amblard, horticulturist, at Clermont-Ferrand, and produced several double-flowering varieties, one of which was named Gloire de Clermont, and sold to M. Louis Van Houtte, of Ghent, who changed the name and sold it under that of Ranunculiflora. Another double variety existed at the same time in the gardens of Clermont-Ferrand, under the name of Martial Champflour, which was of a rather deeper colour than Triomphe de Gergovia. In 1863, M. Emile Chaté, horticulteur, of Paris, went to Clermont-Ferrand, and was struck with the appearance of these double Zonal Pelargoniums, and bought the stock of Triomphe de Gergovia and Martial Champflour. In June, 1864, he sent some flowers of Triomphe de Gergovia, to which he had given the name of Auguste Ferrier, to M. Victor Lemoine, horticulturist, at Nancy, who immediately used the pollen of these flowers to fertilise Beauté de Suresnes, the finest single pink Zonal yet in existence, and obtained, from this artificial fecundation, in 1865 Gloire de Nancy, well known by all horticulturists, and till now the best formed double Zonal. In 1866, he obtained, by the same process, Triomphe; in 1867, Madame Lemoine, the first double cherry-pink Zonal, and Wilhelm Pfitzer, double scarlet; Marie Lemoine, one of the best of bloomers amongst the double Zonals; Le Vésuve, double red; Victor Lemoine, and Stella. National, Signet, Duc de Suez, Sapeur Pompier, Floribunda, Volcan, Prince du Teck, and several others sold in England by Messrs. Bull, Henderson, Carter, &c., are all seedlings of Victor Lemoine, although those who sold them did not acknowledge their origin. In 1869, I obtained by artificial impregnation from Boule des Hespérides, by Gloire de Nancy, Victoire de Lyon and Clemence Royer, the first of a purple shade, and the latter of a pure rose. In 1871, I obtained Charles Darwin, François Arles Dufour, and Emiliô Castelar, all three more or less crimson. In 1872, I obtained the first double white, Aline Sisley, by artificial impregnation of a grand-daughter of Madame Vaucher by a double red of my seedlings. A great many double Zonals have been raised by Alégatière, Chaté, Crousse, and Aldebert, but all resembling, more or less, Gloire de Nancy and Madame Lemoine. The great and interesting facts are, that the first double Zonal Pelargonium was found, some fifteen years ago, at Clermont-Ferrand, where it had been overlooked for several years, and that the first improvement in form and colour was obtained by M. Victor Lemoine, of Nancy, and the first double white from seed by me

JEAN SISLEY.

PHŒNIX SYLVESTRIS.

NEARLY all Palms, when in a small state, are specially valuable for decorative purposes, and, for the indoor decoration of apartments they are preferable to nearly all other fine-foliaged plants. Their leaves, being of stout hard texture and having a glossy surface, withstand the dust and aridity of heated rooms much better than Ferns, Selaginellas, or similar soft-leaved plants grown for their beauty of form alone, while they are equally valuable for grouping along with flowering plants and early spring bulbs. In the culture of Palms great variety may be indulged in, as they vary considerably in habit. The species here figured has a rigid bristling habit of growth, and looks well in nearly any position in which it may be placed. I recently saw it in the Pine-apple Nursery, planted in an Italian basket, and neatly fringed with *Isolepis gracilis*, the effect produced by the combination being excellent. The foliage of this species is of a pale-green tint, and being of free growth, it is one of the best that can be employed for ordinary decorative purposes. It is of a dense dwarf character, and is useful for grouping along with *Chamædoreas* and other slender-stemmed species. It is nearly allied to the common

Date Palm (*P. dactylifera*), but it is more elegant in habit of growth than that kind. Like most other Palms, it grows freely in fibrous loam, and requires a liberal supply of moisture at the root. During the summer months, it may be planted or plunged outside, in sheltered positions, as a sub-tropical plant.

F. W. B.

Phoenix sylvestris in the Pine-apple Nursery.

VARIEGATED FERNS.

AMONGST the great number of Ferns which are now in cultivation, I can only find about a dozen which can be said to be variegated. These, however, are all very distinct and beautiful, and some few of them, if not all, should find a place in every collection of plants; indeed, I cannot too strongly recommend some of them for the beautiful effect which they produce in a Fernery, more particularly when planted out in a naturally constructed rockery, either under glass or in the open air, according to their hardiness. It is a remarkable fact that the genus *Pteris* should, up to the present time have yielded the greatest number of variegated forms, whilst that large and beautiful family of Maiden-hairs (*Adiantum*) have not, up to the present date, yielded us a single variety with

variegated leaves, except those whose young fronds assume a beautiful rosy-red. This, however, cannot be accepted as variegation, but it serves to heighten the desire to possess a plant which would always maintain such lovely tints. With one or two exceptions, variegated Ferns are easily grown. Like all Ferns, they must have good drainage and a liberal supply of water both from the watering-pot and syringe.

Dryopteris nobilis.—This is a member of a small genus remarkable for dwarf and compact habit. The present species, however, is the only member having variegated leaves, and, curiously enough, is the largest grower; the fronds in a young state are simple and entire, and sagittate in shape, deep green in colour, with a broad continuous band of white up the centre. As the plant increases in size and age, the fronds become palmate, whilst the centre of each segment retains the band of white. The under-side is light green, ornamented with a broad band of marginal sori, in the way of *Pteris*, from which genus it is distinguished chiefly by its reticulated venation. It requires the temperature of a stove, and should be potted in peat and sand, with the addition of a little light loam. Native of Brazil.

Elaphoglossum L'Herminieri.—This is a member of the *Acrostichum* family, distinguished by simple entire fronds, and free forked veins. It is a large genus, containing many fine ornamental kinds, this species being, perhaps, the most beautiful; indeed, its style of beauty is entirely distinct from that of all other Ferns.

The fronds of this species are from 1 to 3 feet in length, and from 2 to 3 inches broad, thick and leathery in texture, and of a most peculiar and beautiful bright lustrous blue, reminding one of the back of a mackerel. It forms a beautiful object when planted in a pocket in the Fernery, or when placed in such a position as will allow its long, ribbon-like, iridescent fronds to hang down over a prominent rock. It requires the heat of the stove Fernery, and should be planted in peat and Sphagnum Moss. It is a native of the West Indies, some parts of Brazil, and Central America.

Athyrium Goringianum pictum.—This has been proved to withstand unharmed the severity of our winters; nevertheless, I would always cover its crown with some old fronds or dry leaves. Here I would fain make a slight digression. I have often advocated the cause of cleanliness; but experience has taught me that it is possible to be over-scrupulous in matters of this kind connected with the hardy Fernery; for where too much attention has been paid to smart keeping, I have had complaints that even British Ferns were not hardy; and no wonder, for when old fronds are cut clean away, the crowns are so much exposed to cold that they are killed. Besides this, all the dead leaves are carefully raked and cleared away, and thus all the protection Nature gives them is removed. Under such conditions, it is not to be wondered at that many deaths occur in the hardy Fernery. To prevent this, I advise the leaves to be kept round about the crowns of outdoor Ferns. These may be kept from strewing about by having some fronds of the common Bracken pegged round and over them. The plant now under notice is a valuable addition to any collection of outdoor Ferns; the fronds attain a length of about 1½ feet, they are broadly lanceolate in outline, two or three times divided, and dark green; along the centre of each of the pinnæ there is a deep reddish band, which is again bordered with white, rendering it very distinct and attractive. It is a deciduous plant from Japan.

Athyrium japonicum variegatum.—This is another Japanese plant, and, like the previously named one, perfectly hardy. It is, however, somewhat rare. In general appearance it resembles a lax form of our own Lady Fern, with a good proportion of the pinnæ of a white colour. It is a deciduous hardy species.

Scolopendrium vulgare variegatum.—A dwarf variety of our common Hart's-tongue Fern, with fronds bright green and variously striped with narrow bands of white. It is very pretty, but as it does not assume large proportions, it should be planted in a snug place in the Fernery.

Asplenium Adiantum-nigrum variegatum.—This is another instance of our native Ferns putting on a parti-coloured coat in order to rival, it would seem, their exotic relatives: the deep bright green of the fronds of this plant are irregularly streaked and blotched with pure white. It is a distinct and beautiful form, unfortunately somewhat rare.

Polypodium vulgare variegatum.—This plant is rather apt to lose its variegation, and for a time to produce only green fronds; when variegated it is irregularly splashed with yellowish white.

Pteris argyrea.—This is, perhaps, the most beautiful of all the variegated Ferns. In a young state, it is very useful for table decoration, but, when mature, it forms a splendid object in the Fernery, and may be either grown in the cool or tropical house; the fronds are once or twice divided, and grow from 1 to 4 feet in height, the pinnæ being broad and pinnatifid. The greater portion of the pinnæ are of a bright lustrous metallic white, the edges forming a border of light green. Native of the East Indies, at considerable elevations.

P. cretica albo-lineata.—This is a very handsome Fern, and one that, from its compact habit and hardiness, comes within the reach of all Fern lovers. It originally came to this country from Java, but was probably taken there by the Dutch. A friend, writing to me from Japan, mentions it as being a very common plant in that country. The fronds are pinnate, about 1 foot or 15 inches high, the pinnæ long and pure white, bordered with bright green. It is a very beautiful greenhouse plant, and so hardy, that, with a little protection, it may be kept in the open-air Fernery. Of this I can speak confidently, having grown it so for several years.

P. aspericaulis tricolor.—Nothing can exceed the loveliness of this plant, if in good condition, but this is a great drawback to its cultivation, and I am inclined to think most amateurs fail with this plant through not giving enough water to its roots. The fronds, however, should not be wetted. The fronds are pinnate, the pinnæ broad and pinnatifid, the centre of each of the pinnæ is bright rosy-red, bordered on each side by a band of white, which is finished off by an outer border of dark shining green. It is a truly lovely plant, a worthy subject for the amateur's skill in endeavouring to cultivate it. Must be grown in the tropical Fernery. East Indies.

P. serrulata variegata.—A somewhat robust form of serrulata,

marked in a similar manner to *P. cretica albo-lineata*, but narrower in the pinnæ, and these are slightly serrate at the edges; it is a free-growing pretty plant.

P. nemoralis variegata.—This is a very pretty plant, somewhat resembling a small form of *P. argyrea*, but the white in the pinnæ is beautifully suffused with rose; it may be grown in the temperate Fernery.—*Villa Gardener.*

THE DOUM PALM OF EGYPT.

(HYPHÆNE THEBAICA.)

IN Europe and America the food of the people consists principally of cereals, farinaceous roots, and meat of various sorts; but in Upper Egypt and in places extending to the centre of Africa the fruit of the Doum Palm forms for the poor their principal food, and its infusion with Dates both a pleasant and daily drink and an agreeable and reliable cure for fever. The Doum Palm yields neither resin nor gum, but its leaves furnish roofing and material for the construction of dwellings. The trunk split and freed from pith, forms the uprights, and all other wood used in constructing the house. It also makes water-troughs and palisades for enclosing houses and gardens. The down which is attached to the young leaves serves for filling mattresses and pillows. The ribs of the leaves and fibres of the root-stalk form baskets and brooms. In the year there are two harvests of the fruit, which is the size of an Orange, but of an irregular shape. The outer skin, which is red, is peeled off, and around a kernel is a spongy dry substance, which is the food of the poorer population of Upper Egypt. In the Thebais, the Doum Palm forms extensive forests, the roots spreading over the deeply-buried ruins of one of the largest and most splendid cities of the ancient world. The Thebais is a district situate in the south of Upper Egypt, on which stood the magnificent city of Thebes, erected, it is said, fifteen centuries B.C. When at its greatest splendour, Thebes extended over more than thirty-three miles. This magnificent city was constructed with gigantic blocks of stone, so calculated to withstand the ravages of time that until now it might have stood for the admiration of the world. But man destroys as well as creates, and Thebes was ruined by Cambyzes, King of Persia, B.C. 521. Few traces of the city were to be found in the second century of the Christian era; but the remains of other cities on the Thebais—Luxor and Karnak on the eastern side of the Nile, and the Memnonium and Medinet Habou on the western side, with other ruins—extend now over an area of nearly twenty square miles. Ruins of palaces and temples, colossal statues, pillars, and obelisks are still standing, or cover the ground in confusion, the sand drifting here and there, and occasionally covering some of them. These grand remains astonish the beholder by their size and magnificence, and among them the wandering Arabs, or the very poorest class, to whom the Doum Palm is food and drink, find shelter. Gournou, in Thebais, was for centuries the burial-place of the Pharaohs. In these sepulchral tombs hollowed out of the rocks the poorer Egyptians have taken up their abode. Their once occupants, buried with all the pomp of a royal race, have had their remains long since scattered. The Pharaohs, the grandest rulers of Egypt, whose number was legion, and the conquerors of Egypt, of whatever nation—whether Persian, Babylonian, Greek, or Roman—have all passed into oblivion, and their works have followed them; while the bread of life for man flourishes above the ruins and lends its charm to a desolated region. [Of this Palm an illustration will be found at page 173 of our first volume.]

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Winter Covering.—I find a dozen or two good mats to be of great service during the winter months in protecting greenhouses from frost, especially from the white frosts so peculiar to our winters. In bright clear days, when the sun emits a little warmth, it is well to utilise this by closing the houses early, and whilst the warmth-giving rays are upon it. This heat will prove of great service in the event of frost at night, if, as the daylight begins to wane, a few good dry mats are carefully placed securely over the roof and ridges of the greenhouse; then several degrees of frost may be safely excluded, and, should cold, dull, frosty days prevail, the mats could remain on the glass, as a little extra darkness can scarcely injure them in a cool temperature and a state of rest. When the mats are removed it is well to have a convenient rail over which to throw them.—A. D.

Linum trigynum.—I am pleased to see in your account of Chatsworth (p. 7) favourable mention made of this useful winter-blooming plant, of which we have several in our conservatory, strong, healthy, and flowering profusely. My plants occupy a narrow border alongside the pathway, where they are a little warmer than they would be in an ordinary greenhouse. They receive no attention beyond a little pruning in March after they have done blooming, and before they begin to grow, and, throughout the summer, plenty of water, which I apply overhead through a fine rose as a preventive of red spider, to which this *Linum* is very subject. The soil in the border is a light turfy loam, in which most plants seem to thrive. I also grow these *Linums* in pots placed on shelves in the same house, and, although they grow and flower freely in pots, the preference is decidedly in favour of those in borders.—J. C. L., Aigburth, Liverpool.

THE FLOWER GARDEN.

THE WELSH POLYPODY.

(POLYPODIUM VULGARE VAR. CAMBRICUM.)

THERE are several varieties of *P. vulgare*, amongst which that here figured is, perhaps, the best and most distinct for ordinary decorative purposes. It is a very old variety, having been first described by Linnæus, and is easily distinguished from *P. vulgare* by its having broader fronds, of a light or golden-green colour, and its pinnæ are also much more divided than those of the normal form, which is one of our commonest British Ferns. It is very ornamental when planted out in a sheltered part of the outdoor or hardy Fernery; or it can be cultivated in a cool Fernery indoors, where its fronds come fresher and clearer than when planted outside. When well grown, it is very effective, often producing fronds 15 or 16 inches long, and about one-third that breadth. It grows well when planted in a compost of turfy loam and peat, with the addition of a little leaf-mould and coarse sand. Its bright green fronds are very handy for arranging with choice flowers in the drawing-room vase, or for dinner-table decorations, and they are also very useful for variety in dishing up Grapes, Peaches, and other choice fruits. A remarkable fact connected with this plant is, that it never produces fertile fronds, it being always barren. In the latter respect it differs from *P. var. hibernicum*, the

The Welsh Polypody.

Welsh Polypody, which also has broad bi- or tri-pinnate fronds. This last was discovered in the Dargle, county Wicklow, by Mr. Mackay, and is a fine and distinct form, deserving more extended cultivation. *P. vulgare* var. *serratum* differs from the normal form in its deeper and more marked serratures, and *P. vulgare* var. *bifidum* has its lobes or pinnæ bifurcate at their apices, the apex of the frond itself being also so divided, though not invariably. Those above named are the most distinct of the varieties of *P. vulgare*; but between them there exist other less distinctly marked forms. B.

FLOWERS AT ZERMATT.

HAVE read Mr. Inchbald's letter on this subject with much pleasure, and, having paid a visit to the same locality myself last year, at an earlier season than he appears to have chosen, I can say that the numerous lovely plants he mentions are really a few of the choice things to be found in the neighbourhood of Zermatt. The plant, which in my opinion is the most beautiful of all, namely, *Aquilegia alpina*, I found growing in abundance in one spot only, in a wood near the village; but, though I took up several roots with great care, only one seems at present to be alive. The seed, however, which is abundantly produced in August, will be the means, I hope, of introducing this gem into many English gardens, where, I believe, the true plant is very rare. It grows in dry stony ground under Fir trees, and has a long woody root stock,

stems from 18 inches to 2½ feet high, and very large purple flowers with pale blue centre and white stamens.

Another choice plant is *Primula longiflora*. This I found abundantly on a dry hillside, about three miles north-east of Zermatt, at an elevation of 6,000 or 7,000 feet. None of the plants had more than a single crown, and, though not so brilliant in colour, the flowers are much larger than those of *Primula farinosa*, to which it is nearly allied. Near the same place was growing a beautiful pale yellow Crucifer, which I believe to be an *Erysimum*, the flowers of which formed dense masses of bloom, about 6 inches high. A little further on, by the moraines of the Frudelen glacier, *Senecio uniflorus* was abundant. This plant has silvery-grey leaves in close tufts, and large bright yellow flowers. It was growing in dry gravel at an elevation of about 8,000 feet. The Riffelberg and the Schwartz-see are, however, the best localities for plants near Zermatt. Primulas, Gentians, Soldanellas, and Drabas absolutely cover the ground in many places, while several species of *Ranunculus* (among which *R. rutæfolius* and *R. pyrenaicus* are especially beautiful) flower abundantly on the edge of the melting snow.

Near the top of the Goomer Grat, early in July, *Androsace glacialis* and *Draba rotundifolia* were in full beauty, growing in a mass of grit, through which the melting snow was constantly trickling. The magenta flowers of the latter, almost hiding the plant, surpass anything I have seen, but I fear the plant would be an extremely difficult one to grow in this country. Of Orchids I found but few, *O. nigra* being the only non-British one at all abundant, but the minute *Ophrys alpina* is also found near the Schwartz-see. It would be easy to go on writing of the beauties of the Alpine flora, but, now that the journey is so short and easy, there are few who cannot go and see for themselves. Two hints I may offer to intending visitors to Zermatt—First, try the Hotel des Alpes, the proprietor of which, Ignatz Biner, is the most obliging and attentive host I ever met, and the charges are extremely moderate. Secondly, use the collecting boxes invented by Mr. Atkins of Painswick, which, for bringing home Alpine plants, are admirable. They are nothing but a flat box 4 or 5 inches deep, with the sides cut away sufficiently to admit air, the lid resting on the corners. Plants taken up with a good ball, tightly pressed together and watered now and then, will keep for weeks in these boxes. H. J. ELWES.

NEW BEDDING PLANTS.

FOREMOST amongst plants suitable for carpet bedding or scroll work, is *Stellaria graminea aurea*, a beautiful dwarf-growing, yellow-leaved Chickweed, which rivals the now well-known Golden Feverfew for that purpose, as it does not want the pinching and stopping which that plant requires to keep it within bounds. In Victoria Park, it is used for scroll work, and for clipped edgings. It is perfectly hardy, and easily propagated either by means of cuttings or division. Being a fine-stemmed plant, it dislikes being confined in a warm temperature, in which it gets weak and straggling, and takes a long time to recover itself.

Golden Fleece Thyme.—This is another valuable acquisition for purposes such as have just been described. It grows a little taller than *T. citriodora aurea*, but is still very uniform in growth; it is much more hardy in constitution than that variety, and is consequently more easily wintered. Its leaves are also twice the size of those of the last-named variety. The time when it is in its full beauty is from the middle to the end of summer. It is easily and readily increased by means of cuttings struck in heat in spring, or in a cool frame in autumn; or it may be divided into tufts and kept close for a few days until they get established.

Abutilon niveum aureo-maculatum.—This is a fine plant for mixing with *Coleus refulgens* or Emperor Napoleon in beds. Its leaves are much larger than those of *A. Thompsoni*, and more richly mottled and blotched with golden-yellow, cream-colour, white and green, these colours being beautifully blended together. It also has a fine effect planted in a circular bed, and belted round with *Cineraria asplenifolia* or *C. maritima compacta*, which is one of the whitest-leaved varieties that is in cultivation, having a compact habit. The old *C. maritima* would not do for this work, as it grows tall, and, if cut back, appears ragged and dirty-looking; whereas, the newer and dwarfer varieties with their young tops are always in good order, and are very often taken for *Centaurea ragusina compacta*.

Cineraria ceratophylla.—This is the finest of all the white-

leaved varieties of *Cineraria*; it is beautiful as an edging-plant, as it does not grow more than from 9 inches to 1 foot in height. Its leaves are very finely cut, and of silvery whiteness. It also makes an elegant small specimen plant, planted out singly in small round beds on Grass, with a ground-work of yellow, consisting either of *Thymus citriodora aurea* or of *Stellaria graminea aurea*, both of which are dwarf bright yellow-leaved plants.

Sedum acre elegans.—This is a beautiful addition to carpet-bedding or scroll-work plants, especially when associated with Golden Fleece Thyme, *Alternanthera amœna*, and centre blocks of the beautiful *Coleus Verschaffelti splendens*. It differs in tint from *Mesembryanthemum cordifolium variegatum*, inasmuch as it has more of a pale green hue about it, and meets the eye at once. It is perfectly hardy and easily multiplied by division, as every little piece will grow; it must become a standard plant for carpet-bedding or for scroll-work.

Alternanthera amœna spectabilis.—This, when planted out, will become a very useful plant, as it is in every respect much more robust than *A. amœna*. Its colour is equal to that of that variety, but owing to its being much stronger and about the same style of growth as *A. magnifica*, it will be better to winter, and more easy to produce in quantity in a shorter space of time than these kinds. It is easily propagated in the months of March and April, by means of cuttings struck in a brisk bottom-heat.

Alternanthera paronychioides major.—This is a pretty sport from the older variety, and it comes in useful where a beautiful orange tint of colouring is required. In growth, it is stronger than the old variety.

Coleus Verschaffelti splendens.—This is a fine high-coloured sport from the good old *C. Verschaffelti*. It is several shades paler, and consequently produces a brighter effect than that kind. When this becomes generally known, it will be grown in quantity for bedding purposes in place of *Verschaffelti*.

Euonymus flavescens.—This, I am of opinion, will become a favourite. I saw it in excellent condition in Hyde Park, pegged down as an edging. Its bright shining yellow self-coloured leaves had a fine appearance as a marginal belt round a raised bed of the dark-leaved *Canna* (*rubra superbissima*), which is one of the very best of dark *Cannas* for a sub-tropical bed.

Lobelias.—Two of the speciosa type, with an upright kind of growth, have been very good this season, viz., *Mazarine Gem* and *Blue Stone*. The first of these has dark blue flowers with a tinge or shade of purple, and a small, but clear, white eye. *Blue Stone* is very dark violet-blue, blooms profusely, and has a nice upright growth. I like it very much and expect to see it used largely next summer.

Zonal Pelargoniums.—Of these I have only chosen such as are really first-class as regards habit, fineness of truss, good colour, and free blooming; strictly speaking, first-rate for bedding purposes, viz.:—*Belle Esquermoise*, pure white; centre, very large, and salmon colour. *Beau Villageois*, centre bright salmon, with white margin; very showy. *Blue Gem*, rose, with purple shade; fine, and free-blooming. *Corsair*, scarlet, a fine bedding variety, in the style of *Lord Derby*, but with finer flowers. *Crimson King*, truss, good; a free bloomer, and fine bedder. *Florence Durand*, in the way of *Blue Bell*, but more rosy in colour; a beautiful free-flowering variety for bedding. *Mrs. Quilter*, fine bright pink, extra large truss. *Mrs. Lowe*, fine bright pink; an improvement upon *Lady Louisa Egerton*. *Mary Flower*, deep red; a very fine bedder. *Mr. Hole*, magenta shaded crimson; very dwarf and free. *Mrs. Holden*, trusses of flowers, rosy-pink; a very free bloomer, and fine bedder. *Mrs. S. Musters*, lilac pink; distinct and beautiful. *Sœur Bazille*, bright deep pink or magenta, clear white eye, extra large truss; a splendid variety. *Sparkler*, rich plum-crimson; a very fine bedding variety. *Triomphe de Stella*, leaves small, dark green, flowers of a peculiar yellow colour; a very distinct and beautiful variety, approaching in colour what the late Mr. Donald Beaton described as *Indian yellow*. *Shakespeare*, a fine bright scarlet, with a pip and truss of extra fine quality; this I saw in the dell near the end of the *Serpentine*, in Hyde Park, and I thought it the finest variety I ever saw. Among silver-edged varieties of *Pelargoniums* I noticed two very fine kinds, viz.:—*Bridal Bouquet* and *Miss Kingsbury*. The leaves of the first-named are quite equal to those of *Princess Alexandra*, and the flowers are pure white, bold, and freely produced, as in *Madame Vaucher*. This is really a gem, with white-margined leaves, and fine trusses of white flowers. *Miss Kingsbury* has been one of the best of the season; a bed of it on the Park Lane side of Hyde Park has been very fine indeed this season, both on account of its whiteness of leaf and uniform habit. Among bronze varieties of *Pelargoniums*, I noted three very fine, viz.:—*Maréchal MacMahon*; this has a broad dark zone, belted with yellow colour, and excellent leaf, beautifully formed. *Black Douglas*, zone dark chocolate, with narrow yellow margin. *Bronze Queen*, zone very large, reddish-chocolate, with a small yellow centre and margin;

a distinct variety. Among silver tricolor *Pelargoniums* there are three varieties which I wish to recommend, viz.:—*Fair Oriana*; this has a broad white belt, small green centre, and a very narrow dark zone, habit free and robust, flowers bright pink; very attractive and a good bedder. The *Graphic*, border white, zone rosy carmine; good for bedding purposes. *Sabella*, margins white, zone broad, rose flamed; free and very effective.

Lantanas.—These, in favourable seasons, are good plants for bedding purposes, for which the following four splendid varieties are very suitable, viz.:—*Reine des Fleurs*, which, when at its best, is a large bright crimson, with a good medium habit of growth. *MacMahon*, flowers very fine yellow, changing to scarlet; habit free. *Jacqueminot*, yellow and scarlet-crimson; flower, very large; habit, dwarf and beautiful variety. *Flambeau*, scarlet and orange, dwarf and free blooming. One-year old plants of these are best for planting out.

Heliotropes.—Of these I can recommend *Heloise Delesalle* because it has two good points; one is, that it has a stiff upright habit, and very large trusses or corymbs of lavender flowers, and the other is, that its odour is, I think, all that is required in this class of plants.

Cannas.—Amongst these, the new varieties of the past two years cannot be recommended for foliage so much as for their blooming qualities. The flowers of some of the kinds are now fast approaching in beauty those of the *Gladioli*. The finest are—*Prince Imperial*, green-leaved kind, having fine rich crimson flowers. *Michel Bonne*, also a green-leaved kind, with fine bright crimson flowers. *Compactum*, leaves green, flowers yellow, spotted with red. *Bihorelli splendens*, leaves dark bronzy-green flowers, bright crimson. *Gigantea floribunda*, leaves broad, green, flowers orange-buff. *Rotundifolia rubra*, leaves dark green, flowers orange. *Senateur Chereau*, leaves green flowers yellow, spotted with red. These are all magnificent free flowering varieties, of which I hope to see some fine beds at a distant date.

Wigandias.—These are also fine plants, but although *Caracasana urens* and *Mexicana* are good, they are surpassed by two new varieties, viz., *imperialis* and *latifolia*. Of these the first has a sturdy kind of growth, with large thick leathery leaves, and is by far the best to stand against strong winds. The next grows larger than any of the other varieties; the leaves, which are of great size, are long and majestic, and are ornamented with a white mid-rib, which sets off the plant to much advantage.

Ornamental Kinds of Beet.—*Beta Cicla* or *braziliensis*, these with their different-coloured leaf-stalks, are very beautiful for surrounding beds of sub-tropical plants, or for borders in front of shrubs. The finest collection of ornamental Beets which I have seen was in the Zoological Gardens, Regent's Park; it comprised scarlet, red, purple, yellow, cream, and white, as well as several possessing other shades of colour. These, besides making a fine show in summer, are also valuable in winter, if taken up from the ground, potted, and placed in a warm greenhouse. The new leaves which they push up are satin and ribbon-like, some of them having two or three shades of colour in one leaf-stalk. If these which I saw in the gardens in question had been potted and placed indoors in a warm house, they would have had a charming effect. Beets are easily raised from seed sown in March, pricked off as soon as they are up, then potted singly, and gradually hardened off before being planted out. When potted, they should have a liberal supply of water every day. R. H. B.

DOUBLE PRIMROSE CULTURE.

If your correspondent, "J. N. H." (see p. 30), is growing on the common double kinds of Primroses, such as the white, the lilac, and the sulphur, he ought not to experience any difficulty in rapidly increasing them in any ordinary well-worked garden so especially if it has a sub-stratum of clay. I grew these freely quite in the open ground, exposed to the full heat of the summer's sun on such a soil as I have here mentioned. The plants are lifted annually in October, cut into as many separate crowns as possible, and then planted afresh in another spot, to which a light dressing of rotten manure has been given. These bloom abundantly in spring and grow into several strong crowns during the summer. Advantage should be taken of a soaking rain to give the plants a top-dressing of old pot-soil, and occasionally, during July and August, if drought prevails, a good soaking of water may be given with benefit. As Primroses are somewhat impatient of annual removal, and, therefore, where that practice is adopted, a little additional nurture, such as here mentioned, should be given. With the choicer and less robust dark-coloured kinds more care is requisite, as these only thrive freely in an atmosphere that is moister than our southern summer usually are. Thus they appear to thrive well in some parts of Ireland and in North Britain, but their comparative scarcity further south is, doubtless, chiefly attributable to the heat and drought.

our summer months. They may be cultivated with fair success on a cool north border during summer, but, if the stocks of these should be limited, it is best to lift them, soon after the blooming period is over, and to pot them up singly either into large 60-sized pots, or into small 48-sized pots, and then to plunge them in ashes under a shady wall, care being taken to have a slate or tile bottom for the pots to stand on, in order that worms may not get into them. In such a position, a soaking of water about once a week will suffice, and, if it consists of weak liquid-manure, so much the better. It is important that the plants should be kept growing all through the summer, and that the foliage should be green and vigorous; the blooming crowns for the succeeding spring will be all the stronger for it. About the end of September, if the pot plants have done well, they should be again re-potted, a division of the crowns being made. The plants should then remain either in a cool house or in a frame until the middle of February, when they may be turned out into their blooming quarters. This is the safest and surest mode of culture I can advise your correspondent to pursue. A. D.

Bulbous Plants from Seed.—Can any of your readers give me a few hints on the raising of bulbous plants from seed? I have great difficulty with the seeds of Liliaceæ and others, which require a long time to germinate, as, if sown in pots or frames, and constantly kept moist by watering, a thin crust forms on the surface and prevents the water from penetrating the soil. If placed in a moist shady place, the pots soon get covered with Moss and mould, and, if sown in the open ground, the seedlings are generally destroyed by wood-lice, slugs, and worms. I have tried soot, lime, and other plans to keep them off, without success—the worms being particularly troublesome, as they work up even through 8 inches of ashes. If the soil could be kept in proper state for a year, I should not mind, as most seeds will come in less time; but some, such as *Polygonatum* and *Trillium*, will lie even longer. Has anyone succeeded in raising hardy orchids from seed, and, if so, how? I believe it is the natural way to increase them, and the only one. I see the seed of several species is sold by the ounce in Germany, as though they were commonly grown, but they must be put in principally to swell the catalogues, like many other things. What a marvellous publication is the seed list of a great German firm! I am sure there are more than 10,000 species and varieties in one received lately. Where do they all come from, and what becomes of them all? Sixty distinct classes of Asters, and other florists' flowers in like proportion! 1,500 species of hardy perennials, many of which I venture to say are not to be found in five gardens in Europe, if in any. How many of these are worth growing, even in the largest gardens; and how many of them represent nothing but a name? These questions no one can answer, though they may lead to some interesting reflections.—H. J. E.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Agathæa cœlestis variegata.—I have found this a very valuable addition to the flower garden either for lines or masses, forming, as it does, a compact growth from 4 to 8 inches in height, and being capable of being kept to any desired height with little trouble. It strikes freely in sand or soil, and, from one plant, many hundreds may be raised in this way in a season. I strike it in spring, in shallow boxes filled with sharp sand, on a gentle hot-bed, and winter in a cold house. It will stand 5° or 6° of frost, but a greater degree of cold will kill it.—JOHN NANTCAWEN, *Hawkey Hurst*.

A New Allium.—A recent number of the *Gartenflora* contains a description and coloured figure of a new Allium (*A. oreophilum*), which flowered last season in the botanic garden at St. Petersburg. It was discovered by the Russian botanist Korolkow in the mountains of Akt-Tau in Turkestan. The flowers, which are borne in a moderate-sized umbel, are (as represented in the figure) of a charming crimson colour, with a depth and decision of tone very unusual in the flowers of the Allium family, and are far more striking and effective than those of any other species with which we are acquainted.

THE GARDEN IN THE HOUSE.

THE GLADWIN AS AN INDOOR ORNAMENT.

UNTIL this season, this singular species of Iris seems to have been overlooked in this country, as far as its decorative properties are concerned. I never before used it myself for purposes of ornamentation; but I shall not lose an opportunity of doing so whenever I can obtain any of its bright and effective seed-pods. Arranged amongst evergreens, in stands of any description, it is very ornamental. For Christmas decorations, it should take a leading place amongst berry-bearing plants. Its brilliant orange shade of scarlet, and its graceful drooping habit, make it highly effective in garlands and large decorations formed of evergreens, such as are often used at that period of the year. The seed-pods are sold in bunches in Covent Garden Market at a very cheap rate, which makes them come within the means of all classes. I myself have had some spikes of this Iris, or Gladwin, as it is often called, in use in a stand amongst evergreens more than a month; and, with the exception of the berries having shrunk a little, they

appear quite as fresh as when first placed there, and their colour quite as bright. These seed-pods also look very well if employed in connection with fruit; but they must be mixed with Fern-fronds, or some other foliage. I have placed the pods in the Moss that covers the soil of pot-plants, selecting those which were opened out to their fullest extent, and, placing them so as to rest flat on the Moss; used in this way, they have a very pretty effect. If used in church decorations, they will form, I am sure, a very important adjunct. In "Pratt's Flowering Plants of Great Britain," this Iris is described as having leaves sword-shaped; perianth, beardless; its inner segments about as long as the stigmas; root, perennial. It is not nearly so showy a flower as the Yellow Iris, for its petals are of a dull blue, or, in some instances, a dingy yellow. The plant has a singular odour; but, while it is untouched, this is not disagreeable; but, if we break the stem or crush a leaf, its scent becomes extremely unpleasant. This Iris generally grows a foot or a foot-and-a-half high; and, though a local plant, is common in the west and south-west of England. It is abundant in the woods

Seed-pods of the Gladwin (*Iris foetidissima*).

and thickets of Devonshire, and grows in several parts of Kent in dry hedges, or, as in the neighbourhood of Hythe, along the cliff-coast, and on banks near Dover. It bears its flowers from June to August. Its seeds are very beautiful in winter, when their capsule shrivels, and displays them in all the lustre of brilliant scarlet. They are numerous, and most powerfully acrid. Mr. Sowerby, in "Our Useful Wild Flowers," after speaking of *Iris Pseud-acorus*, says:—"The only other British Iris (*Iris foetidissima*), remarkable for its very peculiar scent, has been applied to the same medicinal purposes as the common species. It is abundant in some parts of the west of England; but it is local elsewhere. The leaves are shorter, narrower, and of a darker green than those of the other kind. The flowers are purple, and are followed by the triangular seed-vessels, which, when ripe, open, disclosing the beautiful orange-coloured seeds, and rendering the plant very ornamental in the autumn." Most of those exhibited in Covent Garden Market for sale come, I believe, from Essex, where, I should suppose, they are cultivated for that purpose; but *Iris foetidissima* is to be found in a wild state abundantly in many parts of southern England and Ireland, as well as in the localities above-mentioned.

There is also a variegated form of this plant, suitable for the garden or conservatory, where, during autumn, it forms a very ornamental addition, its handsome scarlet berries being well set off by the surrounding foliage.

A. HASSARD.

Upper Norwood.

OLEANDERS AS WINDOW PLANTS.

VISITORS to Paris must have noticed the profuse manner in which this plant is cultivated for the decoration of windows, balconies, and the fronts of places of public resort, and, with a little management, it may easily be used for the same purposes in this country. Here at home, it does not flower so well or so generally as could be desired, and this is, doubtless, owing to the wood not becoming well ripened in the autumn. Of late years, some fine varieties of this plant have been raised on the Continent, where the hot dry summer climate suits it admirably. In this country it is rarely grown, although there is no reason why it should not prove a valuable decorative plant under good cultivation. It is readily propagated from cuttings of the last year's wood, which can either be inserted in sand round the rim of the pot, or they will root freely in water. After the cuttings are rooted, pot them off carefully in a compost of sandy loam and leaf-mould, using small pots. The newly-potted plants may now be placed on a shelf in the greenhouse, near the light, and must be liberally supplied with water at the root. When the pots become full of roots, set them in pans of water, adding a little liquid-manure occasionally to strengthen their growth. Cuttings struck in the summer make nice little flowering plants in a couple of years, and go on blooming every season afterwards. Where the older plants are set outside during the summer months, select the hottest corner for them, where full exposure to the sun will ripen their growth thoroughly for next year's bloom. It is no use expecting this or any other hard-wooded plant to flower well, unless thoroughly ripened in the autumn. When the old plants get too large or leggy, they may be cut back, and will soon throw out young wood, and form bushy specimens. The bright, rosy, sweet-scented flowers are nicely adapted for cutting, although their odour is by some considered rather too powerful to be pleasant; still, if the apartment is well ventilated, a moderate supply of these flowers may be agreeable. The plant grows vigorously out of doors on the Continent, and doubtless, like the common and double-flowered varieties of the Pomegranate, it would grow and flower well in this country, if trained along a warm sunny wall and sheltered from cold cutting frosts.

F. W.

A BEAUTIFUL BASKET.

A GREENHOUSE is a place for all kinds of half-hardy plants, but a sitting-room is designed for other purposes, and no plants should be kept in it except such as are highly ornamental. A room should not be subservient to ornaments of any sort, and a table of plants occupying the best place for sitting at the window can be tolerated only if the collection is very beautiful, free from dust, and the arrangement unexceptionable. Anything which interferes with the convenience and comfort of the family, anything which detracts from the order, tidiness, and beauty of the sitting-room should be regarded as a nuisance that ought to be abated. "But what shall I do with all my nice plants?" says the mistress of the house, "I have no other place for them." I will tell you what my neighbour did, and those who choose can do likewise. She made what she calls a basket of a very deep wooden bowl, painted it a delicate colour, and used wire for handles. She threw away her sickly plants, carried her Fuchsias and Geraniums into the cellar, leaving the former in their pots, and hanging the latter up by their roots. Then taking a hint from the way florists fill garden vases in the spring—crowding in a great variety—she transferred the remainder of her stock, consisting of about twenty plants, to her basket, being careful not to break the ball of earth of the most choice kinds, and using a rich compost to fill the interstices. In the centre she placed one or two Callas, around them blooming Begonias, rich foliage-plants, and Geraniums like Mrs. Pollock and Mountain of Snow, disposing each so as to show its finest qualities. To run over the handles and droop from the sides so as to cover the bowl, she planted Ivy, Vines, Ivy-leaved Geraniums, Ferns, Maurandya, and whatever she happened to have. This proximity was favourable; perhaps the roots found their bed a little warmer than before; some-

thing seemed to stimulate the whole collection into active growth, and not many weeks had passed before the basket claimed special attention, and delighted every beholder. It was graceful, airy, exquisite in colours and shadings, and, were it seen behind plate-glass and between lace curtains, it would be thought in harmony with the appointments of the most elegant drawing-room. Perhaps some of us would have less taste in arrangement; we are not all blessed with an artist's eye, and do not appreciate the grace and poetry of climbing floating Vines, and the varying hues of rich foliage, but I am quite sure that measurable success would crown any effort of this kind; and the basket, bowl, vase, or whatever might be used, with its wealth of tender greenery falling from its edge, would look far better than twenty individual, ugly, earthen pots. In arranging cut flowers, we resort to many devices, so with growing plants we can combine them, harmonise their colours, and produce the finest results, and, if our work shows design, much thought, or what art critics call originality, all the better.

J. E. J.

A Niche or Bracket Vase.—A fine figure for a niche, or corner bracket, is a large vase filled with a tall bouquet. Flower-stalks of Gladioli are especially effective in such positions; also branches of Lilies, or individual Lilies of the larger sorts, together with panicles or spikes of medium or more minute inflorescence; Canna, Spiraea, Deutzia, and Delphinium, are always desirable, while boughs of pendent blossoms—Laburnum, Acacia, Dielytra, Salvia, &c., and all papilionaceous flowers, whether drooping or erect, add much grace to such collections. In filling the vase, it is well to select one elegant blossom or cluster for the centre, the remainder of the group diminishing gradually in size, the stems also of slightly lessening length, so that the bouquet shall present a pyramidal form. Fronds of the larger Ferns, branches of slender lanceolate leaves, and long ribbons of Grass, particularly of the variegated sorts, are the proper foliage. Long pieces of Convolvulus, Tropæolum, and other blooming trailers (only one or two handsome branches, and those of the same plant), should fall from among the group, over the edge of the vase, and wind carelessly around it, and about its support, thus giving an air of lightness and ease to what would otherwise appear stiff and formal. Stateliness is the idea to be conveyed by this grouping, hence the vase must not be crowded. Only a few stalks, and not more than two or three of a species, are required, while one splendid Lily, Peony, or cluster of Roses, is sufficient for the centre. For indoor decoration on a smaller scale, the most suitable flowers are Roses, always, if possible, Camellias, Carnations, Tuberoses, Fuchsias, Azaleas, or Balsams, Lilies of the Valley, and Hyacinths (in their season), with Heliotrope, Sweet Alyssum, and Mignonette; and feathery foliage, of the gentlest green, fringing the dish (a pendent spray or blossom breaking the outline here and there), and slightly pointing the collection at intervals. These flowers are equally suitable for the festive board, or the centre, or pier-table. When there is a large collection of plants, others, of a similar character to the above, will suggest themselves as appropriate subjects for arrangement in vases.

—*Horticulturist*.

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

Tree and Climbing Carnations.—I shall be much obliged if you will give me some advice about these Carnations, of which I have read so much. I am an invalid, I love flowers constantly in my room, and particularly in the winter. I am anxious to know whether the Tree Carnations or the climbing kinds are the most continuous bloomers, and as I want three to bloom from November to April, which kind had I better buy?—K. B. [Climbing Carnations are merely a slender-stemmed kind of tree Carnations, and, like them, are continuous bloomers. For winter flowering, we would select La Belle, white, a kind that blooms profusely from November till April; Vulcan, a scarlet-flowered variety, blooming at the same time as La Belle, and having a habit similar to it; and Miss Jolliff, a dwarfish pale salmon-coloured-Carnation, and a most profuse winter-bloomer.]

Dracenas in Sitting-rooms.—I shall be glad to know if *Dracena indivisa*, *D. terminalis*, and *D. australis* will be hardy enough to stand the winter in a flower-stand in the drawing-room, where there is generally a fire.—K. B. [The three *Dracenas* named may be grown in a sitting-room window in summer, but during severe frosts in winter they would, we fear, suffer. If set, however, in a Wardian case they will keep fresh and healthy, and, if gas is used for illumination, they will thus be protected from its deleterious influences. Plants in rooms have aridity and dust to contend with, as well as extreme temperatures, and in order to keep *Dracenas*, Palms, and similar plants in health, they must be regularly sponged over with clean water at least once a week.]

Eupatorium ageratoides a Bouquet-plant.—The Montgomery Horticultural Society recommends the White Snake Root (*Eupatorium ageratoides*) for bouquets and floral ornaments. It combines the qualities of a profuse bloomer, is hardy, and effective in masses, and thus forms an attractive object for garden culture. The large compound corymbs of white misty-looking flowers are precisely what our professional florists desire, and we wonder its merits have so long been overlooked. It is quite common in the North, and continues in bloom for a considerable time during the months of August and September. A botanical friend, who has been in the practice for several years of gathering into his garden our finest native plants, says this is one of the best of all. It is readily propagated by division of the roots, and is never injured by the cold of winter or the droughts of summer.

THE COLOURS OF FLOWERS.

At a meeting of the Croydon Microscopical Club, held on the 17th ult., the following interesting paper on "The Colour of Flowers of Temperate as compared with those of Tropical Climates," was read by Charles Jeeks, Esq.:—Mr. Wallace has stated in his "Malay Archipelago," that the colour of the flowers, and indeed of vegetation generally, is not so brilliant in tropical as in more temperate climates, and we also find it stated in a book on "The Chinese Seas," by Dr. Collingswood (if I remember rightly), that the same rule holds good with respect to sea-weeds. Now, it is true that these statements are quite at variance with those generally believed concerning the flora of tropical climes; but, coming from the source they do, we can scarcely, I think, dispute their accuracy. Indeed, when we consider the subject, we shall find that such a result might naturally be expected, for amid the dense gloom of a tropical forest but little light can penetrate, and it is, as we all know, light which gives colour. Even in our own climate the colour of flowers is not so brilliant *ceteris paribus* in a dense wood as in an open plain. The idea of brilliant colour especially appertaining to tropical flowers seems, as Mr. Wallace remarks, to have arisen partly from the accounts of travellers, and partly from the fact that in this country tropical plants are generally grown in conservatories, where they are exposed to abnormal conditions of light. It would seem, perhaps, indeed, that while the tropical regions are far richer in the production of vegetable forms, so far as concerns brilliancy of colour, we have the advantage, that is, the vegetation of temperate latitudes is more brilliant in hue than that of tropical regions. How are we to account for this? Partly, I think, as regards vegetation and the colour of flowers, by the following considerations, or, perhaps more properly, suggestions. We know that the colour of flowers depends in some measure, at least, upon the amount of radiation of light. Now, there are three distinct classes of rays from the sun; rays of light, rays of heat, and what are called actinic or chemical rays, which, combined with the others, are probably effective in the production of those chemical changes which all plants more or less undergo. It is then by the absorption and radiation of these rays of light that the colour of the flower is produced, and as in temperate climates, these rays seem to be in excess, while those of heat and actinism are subsidiary, especially, perhaps the former, the result seems to be that in such regions the colour of flowers is comparatively more brilliant than in tropical climates, where, besides the larger amount of heat and actinic rays, and the smaller proportion of rays of light, the effect of these latter is possibly much counteracted by the greater amount of moisture present in the air. It also seems possible that the greater richness of soil which generally prevails in tropical climates may be another reason of the comparative want of brilliancy in the flowers; for, wherever the soil is light and dry, indeed, even arid under the conditions of a clear blue sky and bright sun, we find the colour of flowers in proportion more brilliant, as in certain tropical regions is the case. Coming to our own climate, we shall, I think, find that these suggestions are in some measure borne out; as, for instance, in the generally brilliant colour of our wild flowers. It would seem, then, that a richer soil, combined with a damp atmosphere, and a larger proportionate amount of heat and actinic rays, has the effect of, as it were, deepening, and, perhaps, to a certain extent, fixing the colour of flowers. To refer to our practical experience in such matters, is it not generally true that a dry warm season, with plenty of sunlight and clear blue sky, is accompanied by a more brilliant colour in our flowers, which are also more abundant and true? Owing to the effect of these conditions, the seed is more plentiful; while, under the contrary conditions, the reverse is generally the case. It is true that the deeper colour generally accompanying a mountain flora may seem an exception to this; but it should be remembered that here we generally have the presence to a certain extent, especially on the lower slopes of the mountains, of more tropical conditions as regards a greater amount of moisture. Coming down to foliage, I think we shall find that the conditions above named as probably affecting the colour of flowers have here also a proportionate effect, for the foliage of tropical climates is generally of a deeper colour than that of temperate regions, that of the latter being of lighter hue; and, indeed, the further north we go within the temperate zone, the more, as a general rule, do we find this to be the case, the comparatively greater amount of light rays being accompanied by a correspondingly lighter colour of the leaves. There is, however, one exception to this, and, so far as I know, but one—that of New Zealand—where the foliage is of a lighter colour, more approaching that of our own vegetation; but the climate of New Zealand is one nearly similar to our own in character, in the free access and circulation of air admitting more readily the rays of light, while it naturally increases the extent of evaporation, and also tends to check the superabundant presence of that moisture, which,

as a rule, in tropical climates, owing to the denser character of the foliage, which also helps to produce it, tends to perpetuate the condition of things which we find there, the prevalence of a deeper hue in the foliage. Again, it is, I believe, a fact that dull-coloured flowers generally have the sweetest scent, while bright and brilliant coloured ones have either no scent at all, or a disagreeable one. In our own country, for instance, we find those of brilliant colour, which is perhaps predominant, being comparatively scentless, and that this rule is generally borne out among wild flowers. I think the cultivated flowers are scarcely a fair test, as the colour, and, perhaps, scent too, can be modified to almost any extent. There are, doubtless, many exceptions to this rule, but still I think our own experience establishes it as generally correct. Now, may it not be suggested that the same causes, whatever they may be, which tend to produce more brilliant colour, tend also to lessen sweetness of scent, and *vice versa*? and in tropical regions we know the scent of the comparatively dull-coloured flowers is particularly powerful. The, perhaps, greater number of brilliant coloured scentless flowers found in a state of nature in our own climate, at least, I think, may be in part accounted for by the visits of butterflies, &c.; for as soon as any flower exhibits any tendency to variation in the direction of brilliancy of colour, it is probably visited by these insects, and its propagation thus ensured, the tendency to brilliancy of colour being increased by the law of heredity, and further confirmed by suitable conditions of growth; and it is true that to a certain extent this may take place with regard to dark-coloured flowers (by reason, perhaps, of their sweeter scent); but owing possibly to colour being generally more attractive to insects, and other causes, these latter seem to fail in the competition with their more favoured rivals. It is interesting to consider the rationale of this transportation of a germ from a plant of more or less brilliant colour to another, by the ultimate effects of which the stock is, as it were, established. Now, it is probable that flowers owe their colour to the fact of the existence of a very delicate tissue, which has the property of absorbing some rays, and rejecting others (for all flowers are naturally colourless before exposure to light), but in some cases, owing perhaps to various causes, this tissue absorbs rays of light of a different hue to those which we are accustomed to consider as belonging to the flower in question, and the result is a variation in colour. As soon then as this variation (however slight it be) appears, it is taken advantage of by butterflies, which, attracted, perhaps, by the difference in hue, visit the flower and transmit the germs to another flower in which, in course of time, the variation in colour becomes fixed, partly by the transmission of the germ having taken place at the proper time and under favourable conditions, and partly also from the action of the law of heredity, by which any variation in a plant is, under favourable circumstances, liable not only to be again produced, but absolutely increased in amount with each case of re-production, so that the variation is now developed in an ever-increasing rate, until it becomes more or less confirmed. In connection with this subject, the question suggests itself—do cultivated plants come under the same law as domesticated in contradistinction to wild animals? We know that the former, at least sometimes, are not so fertile as the latter, so that it would seem that by confinement or domestication, a certain degree of change is produced in the reproductive organs inducing partial sterility. Now, there seems reason to believe that, in proportion as a plant tends to vary, so does it suffer in its fertility. It is the domestication or cultivation of plants which often produces variation, and this probably means with cultivated plants, an increase in brilliancy of colour of the flowers, which would seem probably by inference to be attended (at least to some extent) by infertility. The same suggestion may, I think, also be applied to wild flowers, the brilliant colour of which we have seen, to be often caused by variation, but the tendency thus produced to decrease in fertility may be here, perhaps, in some measure counteracted by the continual intermixture or crossing of different species by means of the visits of butterflies, which possibly tends to prevent any excess in variation. Again, as our wild flowers seem to be generally noted for brilliancy of colour (in this respect possibly excelling cultivated ones), it may be suggested that this also is accounted for in part by the greater range of intermixture of different germs. Besides, supposing it to be true that bright-coloured flowers are less sweet scented as a rule than duller coloured ones, it would seem possible that as a flower becomes more brilliant in colour, it also generally becomes less sweet-scented, and it may not be an object with gardeners to produce a predominance of brilliant colour at the expense of sweetness of scent. Now, if the above theory of colour in flowers be correct, it would seem to follow that we have some reason for the supposition that, as in a comparatively equable, warm, and damp climate (the latter word implying the probable absence to some extent, at least, of the light rays of the sun)

devoted, with few exceptions, to shady avenues and fruit-trees, fringed with Myrtle hedges and flowering shrubs. A large portion of the garden was devoted to Orange and other trees of the Citron family, and it contained the greatest variety of this useful and interesting class of plants ever seen, perhaps, in Egypt. The accounts given of the quantity of Oranges of every kind, Citrons, Shaddocks, sweet and sour Limes or Lemons, produced in this garden, seemed fabulous. This garden (as were all the gardens in Egypt that were made and planted at the time Shubra was formed) was laid out in square compartments, formed by means of straight and rectangular paths, broken by equi-distant circular groves of shade-trees, such as Acacia Sedbeck, Ficus indica, and F. elastica. Halim Pasha had completed a new palace at Shubra in 1862, round which Mr. Chapman formed some interesting terrace and other gardens, into which were introduced many fine trees and shrubs from Europe; yet a large portion of the Shubra Garden remains as it was in Mehemet Ali's time. The Orange and Lemon gardens are still there, and the beautiful marble kiosque, with its lions and fountains. This kiosque was a favourite lounge of the patriarchal Pasha, and consists of a raised square court, the parts seen from the garden being merely blank walls. In the interior, is a large marble basin, nearly an acre in extent, into which lions and griffins jet water. In the four corners of the building are a billiard-room, breakfast-room, bed-room, and library, a covered promenade connecting the whole, which is lighted by gas. Shubra is about four miles from Cairo, from which it is approached by a fine avenue of Fig trees. PETER WALLACE.

THE FRUIT GARDEN.

INFLUENCE OF THE STOCK ON THE SCION, AND VICE VERSA.*

BOTH theory and practice teach us that the relationship existing between the root and the top of a tree cannot be impaired, to any great extent, by any artificial intervention of man. The very moment that an inserted bud or graft commences to granulate and then unite, that moment the two parts of the embryo tree struggle, as it were, for the mastery. That is, certain idiosyncrasies, inherent either in the branches of the one or the roots of the other, will form a leading feature in the mature plant. Abundant proof of this is afforded by examining the roots of nursery-grown Apple trees, whether budded or grafted. Take for instance some well-known variety, as the Bellefleur, and the roots will be found uniformly long, slender, and very fibrous; other kinds will prove exactly the opposite. If we place a graft of some well-marked variety upon any ordinary stock, say 5 or 6 feet high, in a few years certain peculiarities of the bark will be found extending down from the branches to the body of the tree; as is instanced in the Newtown Pippin Apple and Van Mons Leon le Clerc Pear. Another curious feature respecting the influence of the scion upon the stock, is noticeable in some of the so-called "sports," or variegated-leaved plants. During the past season, a Mountain Ash, upon which was budded a variety with variegated leaves, commenced to push forth young shoots from the main body of the tree, below the point where the bud was inserted. In every case these had variegated leaves. Now, in view of the fact, that these *adventitious* buds were there in advance of the original variegated bud, the presumption is, that they were created green, and their normal condition yielding to the controlling influence of the new branches, caused the change to occur by the flow of sap from above. A still more remarkable case than the one above cited, was related by a correspondent of THE LONDON GARDEN. He states that he procured scions of a diseased Horse Chesnut with yellow leaves, and worked them upon strong, healthy young trees. Some time thereafter, upon examining the stocks where the scions had failed, young shoots were found down the body, bearing the identical yellow-hued foliage; and yet, where the buds originally inserted had "taken," they produced perfectly healthy green leaves. This disease, for I hold that all variegation is in some manner unhealthy, had evidently been communicated from the bud or scion to the stock before the death of the former, and for a short time, during its vain struggle for existence, contaminated the parts below. The Scientific Committee of the Royal Horticultural Society of England, also records a like case with a yellow-leaved Laburnum. After the inserted bud had died, variegated shoots were noticed issuing from the stock, both below and above the inserted point. And Dr. Masters

has stated that an Abutilon had thrown out variegated shoots after grafting with a variegated variety, but ceased to do so after the inserted graft died. But, in some instances the stock exerts a marked influence upon the scion, thus showing the co-operative system in use between them. An instance is mentioned of a couple of Muscat Vines worked on the Black Hamburgh, in the same house with a Muscat on its own roots. Those worked on the Hamburgh start fully five or six days in advance of the one on its own roots, although they are nearly a fortnight behind the Hamburghs they are worked on. It is a curious fact that there has never been seen any difference in the ripening season, nor any effect on the fruit. As we stated in the commencement, certain marked peculiarities will sooner or later always make themselves known; sometimes it will be one thing, and again another and totally different feature assumes the superiority. The governing cause, involved in mystery, as it is, to a certain extent, affords us a clue by means of which we may study a very useful lesson in plant life. We know that all vegetable growth arises from a cell, and what are termed young shoots, leaves, blossoms, &c., are, in fact, but an accumulation of cells, which, in time develop woody fibre and other organs. The propagator of new varieties knows that a single bud, or a section of a young branch, may be inserted in a different tree, and these will unite and produce fruits and flowers similar to the kind from which said bud or graft was taken. Now, let us inquire into the changes that occur during this growing process, or, as horticulturists term it, "taking." Between the wood and bark is where active growth takes place, and the layer of young cells found here is known as the Cambium layer. All growth, of whatever nature, is by cells, the origin of which is, however, at present unknown. But this cell-growth is accomplished by small protuberances, making their appearances on the walls of the older cells, and these rapidly increase, and again, in turn, assist in the formation of others, and this is carried on so long as growth takes place. Without going into a long dissertation upon the subject of cell-growth, which would form a long essay in itself, I will merely state that the question has been asked in relation to a budded tree—Can the cells at the point of union, be partly of one variety and a part belong to another? My theory is, that a cell, singly, is entirely a component part of the variety from which it originates, either from the scion or stock, and is invested with all the powers and principles inherent in that part. A single cell cannot be of two varieties, but a collection of cells, as, for instance, the cellular tissue, may be formed partly of both. The vascular or fibrous tissue is governed by the same laws, each separate, but the little bundles of woody tissue uniting by their outside covering or walls, thus form a compact mass of wood, and the bud or graft has taken, which ultimately forms the future tree. A bud is, in fact, an embryo tree. It contains within its protective covering all the elements of tree growth, with all the organs of vegetation and reproduction intact. Therefore, when a bud is inserted beneath the bark of another plant, the cellular growth at once takes place on both sides, these unite by their outside walls, and the so-called sap commences to circulate in the inter-cellular passages from one to the other. It is, therefore, no wonder that certain peculiarities embraced in the root may be found developing in the scion or top, and *vice versa*. That the scion is enabled to re-produce its kind, is due to the fact that its young growth is merely an increase of cells already formed, and the variations alluded to at the commencement of this paper are the result of constant currents of sap flowing between the two remote portions of the tree, and at the same time imbuing the one with certain marked characters, contained previously in the other.

Thus, in a somewhat hurried, and, I fear, very imperfect manner, I have alluded to the influence of the stock upon the scion, and *vice versa*. This interesting subject is by no means all theory, as many suppose, but is the result, for the most part, of close examination by means of the powerful lens. Future investigation will, undoubtedly, reveal many novel features which we now know not of, and, to accomplish this fully, the patient student of horticulture is asked to join the botanist in the pleasant task. But there is another and more popular aspect to this subject—the relative advantages of certain stocks for particular species of plants. Under this heading, we may take for example the Plum worked on the Peach. Prejudice and distrust, on the part of many cultivators, have done this operation great injustice. By the owner of a heavy soil, where the Plum root thrives luxuriantly, Peaches should be planted with caution; but, on the other hand, in the great Peach districts, with a light mellow soil, the Peach root will succeed far better than the Plum. Peaches always make a large number of strong fibrous roots, and return to the top a vast amount of nutrition. The junction in certain varieties of Plum on Peach roots is perfect, and the tree is long-lived and healthy. The testimony of some of our most noted pomologists goes to show that the practice is correct, and a careful examination plainly indicates that the theory is faultless as well.

* Read by Josiah Hoopes to the American Pomological Society.

The subject of dwarfing fruit-trees is not properly understood. The Pear worked on Quince roots certainly dwarfs the tree to a certain extent, and for a few years, but is the process caused by some inherent property contained in the Quince? We think not. Once allow the Pear to throw out a few roots above the point of junction, and the tree becomes a standard. The abundance of sap or nourishment gathered up by the roots and forwarded to the top, causes in most cases a larger and finer growth of fruit, thus showing that the Quince is adapted to these kinds; but take an uncongenial variety, and mark the result. The fruit is often in such cases worthless. Years ago we were told that budding Cherries on the Mahaleb stock would cause the trees to become dwarf. Little did these propagators know that when they annually pruned their trees, this was what dwarfed them, and not the root. The junction in this case is always perfect, and it is a well-known scientific fact that excessive pruning causes debility in a plant, and that, when vitality is checked, the tree becomes dwarfed, as a matter of course. Excessive growth and productiveness seem to be generally antagonistic. A dwarf tree, after the first vigorous growth is over, will, if healthy, produce good crops and mature a reasonable amount of new wood. Some certain varieties of Pears, as, for instance, the Bartlett, never unite properly on the Quince stock—the cellular tissue of each never seems to make a perfect union. Very many trees that we have examined under a strong lens reveal a marked line between the cell-growth of the two, and not, as is the case with other kinds, a lengthening of both cell-growths, one up, and the other down, so that it is very difficult to determine where the exact point of insertion really is. There are causes, over which we have no control, that debar us from dwarfing some varieties, but science has not yet solved the mystery.

THE ASHTON COURT GRAPE PRESERVER.

THE accompanying is an illustration of a useful way of keeping Grapes in water after they are cut from the Vine. Any plumber can make the tins for 6d. each, exclusive of the copper wire by which they are suspended. The Grapes keep well in these preservers hung up in a Vinery; but what I should really like to have would be a small house so situated that by turning a valve one could have heat when required, such house to be properly ventilated; it could be used in the summer months for young Vines in pots, Cucumbers or Melons. Such a place could be kept perfectly free from dust or damp.—WILLIAM DODDS.

Fruit Culture in Nebraska.—At the annual exhibition of the American Pomological Association, held in 1873, at Boston, Mass., the first premium for fruits was awarded to Nebraska. This was the second occasion on which this honour had fallen to that State, a similar premium having been awarded at the Richmond, Virginia, exhibition of the society, in 1871. The Burlington and Missouri River Railroad Company, which owns a large tract of land in Nebraska, exhibited, at the 1873 American Institute Fair, at New York, a large variety of the fruits of the country, and has received three diplomas from the Institute for fruits and other kinds of produce. The same company, as our readers will remember, also exhibited a beautiful collection of fruits at the late Smithfield Club Show.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Apples for Northumberland.—Will any of your readers tell me from experience what first-class dessert and kitchen Apples I may plant with confidence in this part of the country? They must thrive as standards. I am about forming what I hope will prove a good orchard.—J. H., *Northumberland*.

Pears by the Sea.—Passing by the shore from Newhaven to Eastbourne the other day, and not expecting the least interest in the way of gardening along that exposed garden-less and tree-less walk, we were surprised to see some noble Pear trees trained against the side of the large tide mills near Newhaven. They are as fine examples of training as we have ever seen, and run from 20 to 30 feet high. They have borne many good crops. Some years ago, a gutter was put over them to prevent the water falling from the roof on the flowers. Since this has been done the crops have never been nearly so good. The roots having only a restricted road-way to feed in, the trees suffered from want of the roof-water. The fact is instructive.—R.

SOILS, FERTILISERS, &c.

THE DIFFERENT MODES OF PREPARING SEWAGE MANURE.

OUR readers will, no doubt, be interested by the following excellent summary of information relative to processes for the utilisation of town sewage. It is from one of the able articles included in the "Companion to the British Almanac." Dirt was defined by Lord Palmerston to be matter in the wrong place. The sewage filth, which in our large cities is one of the most dangerous enemies of public health, a constant source of annoyance and fear, would in its proper place be a valuable fertiliser of the soil, and aid in increasing the quantity and quality of the fruits of the earth for the food of man. Amidst the contending claims of the numerous sewage systems there is perhaps some danger of the public growing weary of the subject, and regarding it as a matter for the judgment of experts alone, and without any interest for anyone else. Such a result would be greatly to be deplored. The nation has a very vital interest in the sewage problem, and a just appreciation of this fact must precede any successful attempt towards its solution. The problem is, first, how to dispose of sewage in such a manner as to be harmless in its effects on public health; and, secondly, how to realise the vast potential wealth which is now thrown into the sewers. Our rivers are polluted to an almost incredible extent. The Thames receives the sewage of 880,000 persons before it comes into the hands of the water companies. "This water contains a larger amount of impurity derived from fœcal matter than filtered sewage." The influence of this matter may be clearly traced in the epidemics of typhoid fever, and there can be no reason to doubt that the double contamination of air and water has a most deleterious effect on public health. But this matter, so offensive and detrimental when misapplied, has a very high potential value. We will now briefly mention the plans proposed for getting rid of this noxious waste, and utilising its valuable properties. For the removal of the excreta of the human body, and the refuse of the household, there are two essentially different plans, each having violent partisans. Whether the system should be based on earth or water is the primary contention.

Dry Earth System.—Experience has shown that earth carefully dried until it has become a powder absorbs and renders inodorous offensive substances, if applied in sufficient quantities to absorb all the fluid matter. The dry ash of hard coal or anthracite may be used instead of earth. This plan is impracticable in large and densely populated cities and towns. 4 or 5 lbs. of dry earth would be required daily for each individual. A city of 100,000 people will involve bringing in 250 tons daily from the surrounding country, and distributing it to, perhaps, 15,000 different houses. In the country, and in many establishments situated where there is plenty of land from which to take the earth, and to which the manure might be returned, the system could be advantageously adopted.

Water Carriage System.—All towns are obliged to have sewers and drains to carry off the surface-water falling as rain, and to drain the soil of its too abundant moisture. The houses are connected with the sewers by water-closets, &c., and the sewer gases seek a passage by these channels into the interior of the houses. Sewer air is not fetid, nor pungent, nor ammoniacal; it has no marked characteristic of its own. If it were foul-smelling, its presence would excite greater attention than it now receives. When it escapes from the sewer into the dwelling, it carries with it a virulent poison, and the air is filled with the seeds of disease. A storm of rain, or even a change of temperature, may cause it to rise through any unlucky leak and quickly spread throughout the dwelling. It has been proposed to have a continuation of the soil pipe carried up the roof, and so subject the contents of the drains to the purifying influence of currents of air. The water-carriage system being that for the most part in use, we now turn to the proposals for the utilisation of sewage.

The Lime Process.—In this, the sewage is mixed with cream of milk or cream of lime and violently agitated. When allowed to subside, highly putrescible mud is precipitated, while the liquor flows off in a tolerably clear condition. Drying the mud is a very offensive operation and much of its valuable constituents escapes. The manure has sold for one-third the money it costs.

The Phosphate Process is based on the fact that certain mineral phosphates, when freshly precipitated, eagerly combine with the organic matter in the sewage. Fetid sewage may be deprived of odour and colour if they are agitated in it. Phosphate of magnesia combines with the ammonia contained in the sewage, and precipitates it as double phosphate of ammonia and magnesia. The amount of ammonia is very small, and the plan does not appear to be capable of being worked profitably.

Morfit's Process replaces the natural phosphate of alumina by

a new artificial material, the "mother water," as produced by Dr. Morfit's process for obtaining pure phosphates of lime by precipitation from hydrochloric solutions of mineral phosphates of lime. The result is, in the opinion of the inventor, a valuable special manure for clay soils.

Blyth's Process is an attempt to obtain the ammonia contained in the sewage, and consists in treating it with super-phosphate of lime and a salt of magnesia. Very little success appears to have attended this plan.

In Holden's Process, the sewage is mixed with sulphate of iron, lime, and coal-dust. It yields only three per cent. phosphoric acid, .004 per cent. ammonia, and 0.555 per cent. of organic nitrogen. As a manure, it has, therefore, little value.

The A B C Process is a plan of precipitating by sulphate of alumina the valuable constituents of sewage, and purifying it with charcoal and clay. Its name is derived from the initial letters of the principal constituents employed, alum, blood, clay, and charcoal. Alumina, when in contact with sewage, is separated, and each particle seizes hold of, and drags down with it, a corresponding particle of nitrogenous impurity. All blood is charged with albumen, which coagulates in contact with alum. The treatment with blood precipitates a light hydrate of alumina which ultimately settles, leaving a clear liquid above it, although a slight agitation causes it to float up again. Clay finely ground with water forms a creamy emulsion which takes days to settle, but, in contact with sulphate of alumina, coagulates like albumen. It will be seen that there are three precipitations which occur simultaneously, and result in a dense mass which settles at the bottom of the tank. The charcoal is intended to correct whatever impurities may still remain. It is claimed for this system that it deodorises and disinfects sewage, leaves the effluent water fit for drinking purposes, and produces, at a cost of £2 per ton, a "native guano," having considerable manurial value, and selling at £3 10s. per ton. The reports as to this process are very contradictory. One authority tells us that the effluent water contains as much putrescent matter injurious to health as the sewage itself, whilst another tells us that fish have been kept alive in it!

Irrigation.—Perhaps the most important test that the system of sewage irrigation has yet received has been at Merthyr Tydfil, where Mr. Bailey Denton and Dr. Frankland conducted experiments under the authority of the Court of Chancery. Proceedings had been taken against the town authorities, for allowing sewage to enter the river Taff, and the Board of Health had determined to experiment on 393 acres of land, but, not having been expeditious enough, the gentlemen named were sent armed with full powers. The plan they adopted is thus described:—"About 20 acres of land, immediately adjoining the road on which the tanks are placed, have been arranged into filtering acres or beds on a plan devised by Mr. J. Bailey Denton. The land is a loamy soil, 18 inches thick, overlying a bed of gravel. The whole of these 20 acres has been under-drained to a depth of from 5 to 7 feet. The lateral drains are placed at regular distances from each other, and run towards the main or effluent drain. This is everywhere 6 feet deep. The surface of the land is formed into beds; these have been made to slope towards the main drain by a fall of 1 in 150. The surface is ploughed in ridges; on these, vegetables are planted or seeds sown; the line of the ridged furrow is in the direction of the under drain. Along the raised margin of each bed in each area delivering carriers are placed, one edge being slightly depressed. The strained sewage passes from the conduits into the delivering carriers, and, as it overflows the depressed edges, runs gently into and along the furrows down to the lowest and most distant parts of the plot. The sewage continues to be so delivered for six hours; then an interval of rest of eighteen hours takes place, and again the land is thoroughly charged with the fertilising stream. The water percolates through the 6 feet of earth, and reaches the lateral drains, which convey it to the main effluent drain." The result is that the water is purer than the Thames water drunk in London, and is used by the workmen on the sewage farm. The ridges have yielded large crops of kitchen vegetables, sufficient to compensate for the total outlay, whilst portions devoted to Italian Grass gave a profit of £24 per acre, and a plot of Onions realised £64 per acre. These results appear to be highly satisfactory. What would Dickens have said to the spectacle of the Court of Chancery stepping in to repair the delay of a Board of Health?

Smoke Drainage.—In connection with these sewage schemes, we may notice a suggestion made by Mr. Peter Spence, F.C.S., who advocates carrying the smoke of house fires, &c., through the drains, with the twofold object of purifying the air and sewage. Mr. Spence estimates that, in Manchester alone, 20,000 tons of sulphate of ammonia, which is now thrown into the atmosphere, would be deposited in the smoke-drain.

THE HOUSEHOLD.

EXTRACT OF APPLES.

New processes of utilising Apples have been put in operation in Ohio which place its culture upon an entirely new basis. One process is that of making Apple-jelly, and another that of making "Apple-butter." The jelly is a condensed product, requiring a large quantity of Apples for a corresponding small amount of jelly, and it must, of consequence, be dear, and perhaps it is neither as profitable nor as popular an industry as the other, which uses the whole of the Apples with little condensation. Apple-butter differs from the Apple-sauce of New England only in the manufacture. Apple-sauce is made, or it used to be made, by boiling down cider, that of sweet Apples usually preferred, and of adding pared and quartered Apples when the whole was boiled just enough to make the Apples soft, but not enough to break down the structure. In making Apple-butter the boiling is continued much longer, and the whole mass is thoroughly mixed together by constantly stirring it, and the more thoroughly this process is performed the better is the quality, particularly in regard to keeping. Both preparations are kept in jars, and often in barrels made for the purpose. The chief defect of Apple-sauce is, that when warm weather comes in the spring it is apt to ferment and become sour, when it is necessary to re-boil it. Apple-butter seldom ferments, and, if kept in a cool place, it remains good for years. The commercial Apple-butter factories provide first a cider-mill of improved structure and copper boilers, with tanks for storage and additional treatment, all of sufficient capacity to work up 1,000 barrels of Apples a day. The product is packed in barrels, when it is ready for shipment to any part of the world, and, if properly made, it will keep as well as flour, pork, or molasses, and it is as much of a cash article as either.—*New York Tribune.*

Keeping Apples.—At the West Grove Farmers' Club, T. M. Harvey and Dr. Bush both stated that they had been very successful in keeping Apples packed in barrels with dry forest leaves, placing them in apartments with a temperature just above freezing. Others had succeeded by packing them in sawdust, dry tan, and plaster of Paris. It will be observed that all these modes not only protect the fruit from freezing when any cold weather occurs, but prevent the active currents of air, for it is not only important to keep the fruit cool, but to preserve a perfectly uniform temperature. We have found that merely wrapping the specimens in tissue paper, when kept on shelves, preserved them longer than when exposed, for the same reason—and hence also the advantage of heading up in barrels so long as fermentation and the bad effects of confined air are prevented by a cool temperature and not confining them too long.—*Cultivator.*

Teas of Home Growth.—Somebody, professing to speak from long experience, avers that the leaves of the Raspberry, if properly treated, make finer tea than any that finds its way to Mincing Lane. The French peasants make an aromatic drink from the leaves of the Black Currant tree, and believe it to be a specific for indigestion. Thanks to M. Raspail, they have also learned to appreciate the flavour, aroma, and virtue of Borage tea. Our dietetic philosopher and friend, Fin Bec, would like to do in England what M. Raspail did in France, but, knowing the inveterate suspicion the poorer classes at home have of anything to which they are unaccustomed, especially if it costs little, discreetly declines making the experiment himself. "Let any social doctor," says he, "who may be anxious to test the pliability of the English agricultural labourer as a pupil, accost him with the following proposition: 'My good man, I have, I assure you, from the bottom of my heart, the liveliest interest in your welfare. Now, the tea you drink is detestable, adulterated, and very dear stuff. It does you no good; now take my advice—grow Borage, which will cost you nothing, and drink Borage tea. It helps digestion, is a sudorific, has a delightful aroma, and will have no bad effect on your nerves, or the nerves of your wife.' I am lost in conjectures as to the fate that would befall the doctor. He might be bonneted, elbowed into a Thorn hedge, reminded that the horse-pond was near, or recommended to confine his attentions to his own teacup. But the unlikeliest result of all would be thanks for his suggestion. No, the unlikeliest would be the trial of it."—*Chambers's Journal.*

Apple Marmalade.—Peel, core, and boil the Apples—Spitzenbergs are the best—with only sufficient water to keep them from burning; beat them to a pulp; to every pound allow three-quarters of a pound of lump sugar; dip the lumps into water, put these into a saucepan and boil until the syrup is thick and can be well skimmed; add this syrup to the Apple with half a tea-spoonful of minced Lemon peel to each pound, and stir over a quick fire till the Apple ceases to stick to the bottom of the pan. Dip jelly moulds into water and lay in the bottoms—as they are inverted—a few strips of Citron and some blanched Almonds, then pour in the marmalade, and when cold it will turn out easily.

THE ARBORETUM.

AN ANCIENT PLANE-TREE.

OUR illustration represents the present state of an old historical Plane-tree standing in the Temple Gardens. The Thames formerly flowed close to its roots, and it is now pointed out as marking the site of the old river wall, successive embankments having now shut out the river 50 or 60 yards further to the south. Apart from its interest as a landmark, both Goldsmith and Johnson are reputed to have spent many an hour in "sweet converse" beneath its shade; nor is this improbable, as it has evidently been a stately tree in its time. When the river wall was removed further south, the ground around it was raised to a height of 15 feet, and, probably, this hastened its death by depriving its roots of their due amount of aëration. It has been dead since 1835, and shows little of its former greatness. The branches are rotten and broken, and in a few years' time, if not better protected than it is, it will be among the things of the past. A neat label, giving a short account of its history, would be appreciated by visitors to the Temple Gardens, many of whom are, in all probability, quite unaware of its existence or of its historical interest.

The Yardley Oak.

—The most complete account of Cowper's Oak (see p. 22) will be found in Loudon's "Arboretum," Vol. III., p. 1,765, 1838, at which time he had it measured. He gives the girth, at 1 foot above the ground, as 30 feet 6 inches. The stem then leant so much to the south as almost to admit of a person walking up it with very little aid from the hands. It had three huge branches wholly devoid of bark, and had formerly been much injured by persons carrying away small blocks or slices of the wood as relics, or to manufacture snuff-boxes, &c., from. Cowper's Oak was called Judith, from an old legend that it had been planted by the Conqueror's niece Judith, Countess of Northumberland. She held eighty-eight manors in Northamptonshire, including a portion of Yardley. There is a large engraving of it in Hayley's "Cowper," Vol. III., 1806, supplement. The two Oaks figured by Strutt, and known as Gog and Magog, are quite distinct from "Cowper's Oak." —EDWARD SOLLY, in *Notes and Queries*. [The title to the engraving of this Oak is "Judith or Cowper's Oak, a portrait from Nature, drawn by Mrs. Meen, 1801, engraved by Caroline Watson, engraver to her Majesty, 1805."]

Old Plane-tree in the Temple Gardens.

Destruction of Seedling Ash.—Mr. Alexander Buchan read a paper the other day before the Botanical Society of Edinburgh "On the destruction by frost of seedling Ash trees, in Mr. Robertson's Nursery Ground, near Fettes College, on the 7th April, 1873." At the outset Mr. Buchan explained that, as a precaution against frost, Mr. Robertson spread an old fishing net over a plot of young Ash seedlings, which had all appeared above ground within the previous ten days. He entered into minute details as to the manner in which Mr. Robertson laid out the net, and went on to mention that the loss of young plants was considerable—the extent of it being represented by the fact that only about 400 plants per square yard were now growing in those parts in which the destruction of the seedlings took place, whereas elsewhere in the plot the number was 2,000 to the

square yard. The explanation of the facts adduced by Mr. Buchan was thus stated:—"The steady blowing light wind was sufficient to disturb the air cooled by contact with the ground, and mix it with the stratum of air lying immediately over it, in all places where the wind was felt. Over the beds, unprotected by the net, the wind passed freely and unchecked; and there, consequently, the temperature did not fall lower than was just sufficient to brown, without destroying, the young seedlings. But to the beds protected by the net, the wind had no access, owing to the intervention of the net, and there, consequently, the air strata not mixing, the temperature fell so much lower than over the beds adjoining as to destroy the seedlings, which happened at the time to be just at that stage of their growth when they are most susceptible of injury. From the illustrations which he gave, Mr. Buchan stated that it would be evident that the air enclosed under the net which was spread over the Ash seedlings was practically still, and the cold produced by radiation was thus allowed to accumulate close to the surface over the seedling plants. Thus, then, the destruction of the young Ash plants was due to the net being of too flimsy a texture to offer a sufficient obstruction to terrestrial radiation, whilst at the same time it afforded a complete obstruction to the winds, and thus prevented a circulation of air around the young plants; the destruction, be it observed, being most complete on the borders of the trenches in which the coldest air settled, and

over which the stratum of air imprisoned under the net was less in thickness."

Evergreen Berberries.—I do not find in your interesting descriptive list of Berberries (see p. 31), *B. Bealei* mentioned. I have had one under that name for many years, but it may be a synonym of another variety. It is much like *B. japonica* in character, and flowers as freely every spring, but being, until now, under the drip of a large *Lambert's Cypress*, it has not fruited. I may mention that, in warm, dry summers, my plants of *B. aristata* are thickly covered with purple fruit, with as fine a bloom as that of a *Sloe*, but, this year, like many others, owing to continual dripping, and absence of sun, the long racemes of berries are a shabby red and unripe looking colour. I may add, that I have *Primroses*, in some numbers, in flower on the banks here (in Cornwall); also

some *Narcissi* in flower, and only a few days ago I cut a beautiful *Devoniensis Rose*, and in a few days I hope to gather a bud or two of the *Tea Rose Goubault*.—THE COLONEL.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

***Prunus myrobalana*.**—Can any of your readers inform me if this tree will grow from cuttings? If so, what is the proper time to take them and what treatment should they receive?—J. M.

Mistletoe on the Acacia.—A large globular plant of Mistletoe, high up on the tree, may be seen in the garden of the vicarage, Godnestone Kent.—JOHN MARTEN.

—The Mistletoe may be seen growing luxuriantly on the Acacia in several places in the neighbourhood of Bristol, among which may be mentioned Blaize Castle, and Holmwood, Westbury-on-Trym. It is, however, somewhat remarkable that it does not, so far as I am aware, grow on any of the Coniferae in this country, whereas in the neighbourhood of Gabas, in the Pyrenees, many of the Pine trees (*Pinus pyrenaica*) are literally covered with it.—ALFRED SHIPLEY, *Westbury-on-Trym, near Bristol*.

London Plane-Trees.—Are the Plane-trees which do so well in London squares *Platanus orientalis* or *P. occidentalis*? Some of the young trees sent me by nurserymen as the Plane of the London squares, turn out to be some sort of Maple.—W. Y. [All the large Plane-trees in the London squares are *Platanus occidentalis*, or the American Plane. In Scotland and the north of England, *Acer Pseudo-Platanus* or Sycamore is known by the name of Plane-tree.]

THE KITCHEN GARDEN.

CONDITION OF SUCCESS IN THE GREAT POTATO TRIAL.

WITH reference to the great Potato trial in America, which was reported in *THE GARDEN* some time ago, some readers may desire to know the causes of such marked success, and the following trustworthy document explains it. This report is the production of Messrs. Thurber, Hexamer, and Quinn, three of the most able and experienced of American horticulturists. It should be borne in mind that the prizes were offered for the largest crop raised from one pound of seed, and that a good many competitors grew from 300 to 600 lbs. of Potatoes from this quantity of seed. The committee then condense the leading features of the modes and conditions under which these large crops were produced, justly accounting them of great value to all Potato growers.

Localities.—The largest yield—609 pounds from one of seed—comes from the Far West; but, in proportion to the number of the largest products, a much smaller proportion comes from the Western States than from the east—the very wet summer there, and the ravages of the beetle having, no doubt, caused this deficiency. The geographical distribution of the largest yields gives, from New York, 24 per cent.; Pennsylvania, 16; Vermont, 10; Ohio, 8; Massachusetts, 8; Minnesota, 6; Wisconsin, 5; New Jersey, 4; New Hampshire, 3; Indiana, 3; California, 2; and 11 per cent. from as many different States and territories.

Soils.—The largest product, that of Mr. Salter, was grown "on a very rich sandy loam, rich in decayed vegetable matter to the depth of between 2 and 3 feet, and lying upon a compact formation known as hardpan, which has never been underdrained." Mr. A. Robinson's soil likewise was "a sandy loam, clay sub-soil, where he broke up and raised Potatoes last year." Mr. F. A. Smith planted his Potatoes "in gravel soil with yellow clay sub-soil." Most crops, however, were raised on deep alluvial lands underlaid with gravel; others on light loam with clay or gravelly sub-soil, and in a few cases on heavy clay, highly manured. In but very few instances was the land artificially underdrained, which seems to be a noteworthy fact, as most writers consider drained soil indispensable for the production of good crops.

Manures.—Of fertilisers and mixtures an almost endless variety was used, but the one substance almost invariably applied was wood-ashes. There seems to be no doubt left that ashes are the special manure for Potatoes, and that even very large quantities of them occasioned no injurious effects. In a few cases, as much as one pint of ashes was applied to each hill as top-dressing, and in one instance the sets were actually planted on, and covered with, ashes. Plaster, lime, and salt were also extensively employed, and with great advantage. Strong nitrogenous manures have generally been considered as detrimental to the Potato, but here we find that many successful growers have used large quantities of blood, fish, and Peruvian guano, and hen-manure; also barn-yard manure, at the rate of fifty loads per acre, to the greatest advantage and without producing diseased Potatoes. Whether older and less vigorous varieties would have withstood disease equally well under such a treatment seems, however, somewhat doubtful.

Planting.—The time of planting was, in nearly all cases, during the month of May, and more than one-half of the competitors seem to have considered the 15th of May as the lucky date. In no case were larger sets than of one eye used, and in a majority of instances these were again divided into smaller pieces, so as to give from fifty to one hundred sets from one pound of seed. There appeared to be no difference in the yield between hills with whole eyes and sections of eyes. The hills were invariably placed a considerable distance apart, rarely less than 3 feet each way, and oftener further. As a rule, but one set was planted in a hill, and covered about 4 inches deep.

Cultivation.—It will be hardly necessary to state that, in many cases, the cultivation and care these growing Potatoes received was unremitting and indefatigable. In no case were weeds to be seen in the patch; some of the plantations received semi-weekly hoeings, and all were kept scrupulously clean, and the soil loose and mellow; yet many large crops were grown with but ordinary care. Mr. J. I. Salter states "that the cultivation, manuring, &c., was the same he has given to his general crop of Potatoes for the last five years, and in no respect had there been extra care and labour bestowed." Mr. H. C. Pearson certifies "that these Potatoes were grown with the most ordinary farm culture, being hoed only twice, and receiving no extra treatment in any respect." Nearly all growers adopted the hilling system, and in only two cases were large crops obtained by level culture.

Yield.—Although the Early Vermont gave the largest crop from

one pound of seed, the average productiveness of Compton's Surprise is shown to have been greater than that of the Early Vermont. In explanation of this, Mr. Salter says:—"The Compton's Surprise will, and did with me, with the same culture and soil, yield from one-third to double the amount of the Early Vermont; still, I obtained a much greater yield of the latter than of the former from one pound of seed. The reasons with me are many. In the first place, the number of eyes in the Early Vermont was nearly double that of the Surprise originally, and, in digging, the number was still further reduced by an ugly gash in one of the Potatoes, destroying four eyes. Then, again, I lost five hills by the extreme wet which followed the planting of the Surprise; and then the Vermont, being a very early Potato, matured rapidly, and I was enabled to keep the Colorado beetle in check until its ravages were comparatively harmless on it; while the Surprise, being of slower growth, after the Early Vermont had ripened, required constant attention to prevent their ravages. This time I could not spare, and was forced to let them have it their own way until it was too late; then came an early frost, Sept. 7, which killed the vines of the Surprise, while the Vermont had been out of harm's way from the middle of August." Several reports contain accurate statistics of the yield of different varieties, the result of careful experiments. Taking the yield of Compton's Surprise as 100, the comparative yields average as follows:—Compton's Surprise, 100; Early Vermont, 78; Harrison, 75; Peerless, 72; Late Rose, 70; Early Rose, 62; Campbell's Late Rose, 56; King of the Earlies, 40; Early Goodrich, 35.

Compton's Surprise and the Early Vermont.—The committee conclude, from all the foregoing, that few new varieties have ever before been subjected to so manifold and varied a trial as these two, concerning which the following estimate is made:—"Compton's Surprise has received the unanimous verdict for the most prolific Potato cultivated at present. Yields of from 12 to 20 lbs. per hill are reported by the hundreds, and in one instance 28½ lbs. were dug from one hill. As a rule, the most prolific varieties are not of the best eating quality, but to this Compton's Surprise is an exception. Thousands have testified that they never ate a better Potato. Its uniform mealiness of grain, combined with the purest flavour, and its snowy whiteness of flesh, which is not in the least affected by its blue skin, cannot fail to make it highly valued as a family Potato. This variety shows a peculiar tendency to produce a 'surface crop' not found in other kinds. Its rampant growing vines lying on the ground will frequently take root, and establish a new centre of production. Subterranean branches will also likewise grow above the surface, and form self-supporting plants which produce an additional crop of tubers. The Early Vermont has, as proved by the numerous reports before us, more than sustained its previous reputation. Nearly all competitors declare it from one to two weeks earlier than the Early Rose, and many even more. Its uniform and large size is recognised by every one." Mr. McLeod says: "There are more than 100 in the amount I raised that would weigh from 1 to 2 lbs. each," and Mr. Salter raised one tuber weighing 3 lbs. 12 oz. Its superior cooking and eating qualities are unanimously commended, as well as its compact growth in the hill and its freedom from disease; and with the thousands of cultivators who have grown it alongside of the Early Rose, there seems to be no doubt left that in quality, hardiness, earliness, and yield, it far surpasses that celebrated variety.

Cropping a Garden.—I have a large garden, which I have just changed from a wilderness of noxious weeds to a clean well-tended trenched ground. I have it for two-and-a-half years, so do not want to go to expense beyond what will remunerate my own time. I have little knowledge of gardening. Can any of your correspondents kindly give me a few directions about stocking my garden? I have had a fine set of Raspberries set and well manured. I have just planted some Saskatoon, too late, I imagine for use this season. I sowed early Peas and Managan Beans, how far apart ought the latter to be between seed and seed and each row? I re-planted some Globe Artichokes the other day. I was told it would answer to do so. Can I do anything more in the vegetable way? I have also planted Potatoes, Onions, and Leeks. How deep ought they to be covered? and how far apart in what sized beds—3 feet? I intend sowing and planting the following in their proper time, viz., Cabbage, French Beans, Scarlet Runners, Cauliflowers, Beet, Salad, Celery, herbs, Spinach, Parsley—in a bed or in a border?—C. J. LOXS.

Bones as Manure.—It is found cheaper to dissolve or grind bones than to manure with them. It is well known that the bones of animals are a valuable source of commerce in bones, of which we often import 100,000 tons per annum, valued at \$500,000, while these collected in bones are composed of nearly as much more. Bones of almost all animals are now imported as articles of commerce; whether wild or domesticated animals, they are made to yield parts of their skeletons for some useful purpose; and we import the bones of the giraffe, elephants, horse, cattle, and whale.

THE GARDENS OF ENGLAND.

ESLINGTON PARK.

THIS, the seat of Lord Ravensworth, like many charming retreats in the North of England, lies at a distance from any of the main thoroughfares to the North, and, nestling under the skirts of the Cheviots, is little known to tourists. It is approached through the lovely vale of Whittingham, which can hardly be surpassed for picturesque and natural beauty; about a mile beyond the village that has given its name to the vale, one enters the park, and the first object that attracts attention are its noble trees, conspicuous amongst which, and towering aloft like giants, are various Silver Firs, one of them being about 130 feet in height, and measuring at 5 feet from the ground 15 feet 8 inches round the bole. Proceeding westward along the drive, an opening on the right enables one to get a glimpse of the hall standing upon the left bank of the Aln, which is crossed by a tastefully designed iron bridge of recent construction. It is a plain building in the English style, and in fine keeping with the situation and surrounding scenery. The Aln, which is only a small stream here, and which threads its way round the bottom of a green terrace a few yards distant from the house, formed at one time a lake, but, owing to damp arising from it so near the house, it was drained off, and the little stream now issuing from between the greenest of banks falls over a weir at the farther end of the flower garden. The most attractive feature of this place, however, is its flower-garden, which is both compact and artistic in its arrangement; it occupies an oblong space equal in breadth to the south-eastern front of the building; a terrace, crowned with beautiful Evergreens, runs parallel to it on the right, and divides it from the stream, and along the left side runs another terrace covered with flowering shrubs, while on the top is a broad promenade. The flower-beds, which are upon the grass, are of considerable size, and very effective in autumn; foliage-plants, too, of the hardier kinds are used extensively in connection with flowering subjects; the Golden Thyme acquires a tint here that deepens as the autumn advances, and is really lovely. It seems to prove, in fact, that soil and situation have much to do in bringing out the lovely tints of this charming plant; a remark which holds good with regard to many other plants here that display a depth of colour and profusion of bloom not often seen in the warmer and lighter soils of our southern counties. A shady walk leads from the flower to the kitchen garden, the latter being somewhat distant from the former, and the intervening space, which is considerable, is laid out in a way that is both pleasing and natural. Some of our earliest imported varieties of *Pinus* are growing here with a vigour and freshness that show them to have found a congenial home, and not the least interesting thing about them is, I believe, that they were all planted by the venerable gardener, Mr. Oliver, who has been head gardener here for the long space of forty-nine years. We were fortunate in seeing a fine *Yucca gloriosa* in full bloom growing upon the Grass; on the right hand side of the door opening into the kitchen garden, stands a lean-to greenhouse, in which were some really fine pots of *Liliums* of various kinds. The garden wall here forms the boundary to the pleasure-ground in this direction; it is covered with fruit-trees, but the border along the base of it is filled with choice bedding material, laid out with great taste. We also observed some fine coloured black Grapes in a small house placed against this wall. On entering the kitchen garden, the first thing that attracted attention was the luxuriance and profusion of vegetables within it. Mr. Oliver seems to have carried this branch of his profession to the highest perfection, and his system of training and pruning fruit bushes deserves to be more generally adopted than it is; by careful and constant summer pinching they are kept low, open, and regular in the arrangement of the branches; by this means they acquire a robustness of habit, very different from the long scrambling bushes, too often seen, sometimes even in the best of gardens; dwarf fruit-trees are also treated here upon this principle, and with the same result. Like many old gardeners, Mr. Oliver's forte seems to lie in the frame-ground. He grows his Melons principally upon dung-beds; there are not many kinds of Melons or Cucumbers that he has not had through his hands, and he can tell you their merits and demerits better than any man with whom I am acquainted; the

same may be said of the different *Celeries* that have been in the market. A large square in the kitchen garden is devoted to the growth of *Dahlias*. As we wend our way through avenues of *Hollyhocks*, *Gladioli*, *Stocks*, and *Asters*, the fact is forced upon us, that florists' flowers are not only grown here, but well grown. Until very recently, no fruit was grown under glass here—Ravensworth, another seat of this family, having one of the best fruit gardens in the county—now, however, two houses occupied with Grapes here, furnish proof that this branch of gardening receives due attention. A combination of natural objects, assisted by art, has made Eslington one of those charming places that one leaves with reluctance. The fine old house, partly covered with *Creepers* of different tints, the Aln murmuring past, the deer browsing up to the entrance, the park abounding in fine old trees, each in the varied colours of autumn, all make up a picture surely worth painting by either pen or pencil.

J. T.

GLEN EYRE, BASSETT, SOUTHAMPTON.

THIS is one of the most unique and charming spots in the county of Hants, and, although quite a modern place, yet so luxuriant has been the growth of the trees and shrubs by which it is encompassed, that it is now well wooded and secluded. The house is situated at the head of a pleasant dell looking eastward, and commanding charming views of the surrounding country. Immediately in front of it is a series of terrace-gardens, the banks of which are clothed with a rich verdure of evergreen shrubs, among which *Pernettyas* and *Berberis Darwinii* luxuriate, and the flower-beds are filled with diverse-coloured bulbous flowers, and edged or carpeted with hardy flowering plants in so tasteful a fashion that the floral bedding display will, early in April, form a most beautiful picture; when to this, too, are added the blooms of all kinds of flowering trees and shrubs, varied and pleasant walks, and a constant succession of gardenesque effects, one is compelled to acknowledge that Glen Eyre is emphatically a place worthy of the taste and wealth of its excellent owner—Mrs. Eyre Crabbe. In the gardens at Glen Eyre, *Camellias* thrive apace in the open ground, and, of the old double striped variety, there is probably one of the largest of outdoor unprotected *Camellias* in the kingdom; it is in the highest state of health, and about 9 feet in height and 10 feet through. In all directions, where the *Camellia* is planted out, it thrives well, and, indeed, it is one of our hardiest and most beautiful of border shrubs. Except a small patch of croquet lawn, there is scarcely a rod of level Grass plat in the place. So steep are the inclines, that levels are only obtained by a series of terraces, and, on the Grassy sides of the slopes, superb specimens of *Conifers* are growing; of these there may be larger trees of the various kinds throughout the country, but certainly none handsomer or more compact in growth than are those growing on the Glen Eyre slopes. Of *Wellingtonia* there is a splendid tree, with a trunk some 2 feet in diameter, having a grip of the soil like some vegetable giant, and of *Picea Nordmanniana* there is also a superb specimen. In one nook has been constructed a large interesting hardy Fernery, planted with fine and rare kinds; it lies low, and is overhung with trees, and, being sheltered on all sides with shrubs, the Ferns thrive admirably in it. This is as it should be, for it is contrary to nature to construct a Fernery where the winds can rack the vegetation, or the hot sun scorch it. At the extremity of the pleasure-grounds stands the cottage of Mr. Stewart, the gardener, with its broad front of red brick, its old-fashioned porch, and its warm covering of thatch, literally covered with Ivy and climbing Roses. The glass houses are richly filled with all sorts of Orchids, Ferns, flowering and fine-foliaged stove-plants, hard-wooded flowering plants of kinds innumerable, and a large mass of bedding plants. One of the best private collections of *Primulas* in the country is grown here, including the double sorts with self and flaked flowers. The double forms are exceedingly tender, and very difficult to propagate, hence the reason why good double forms are so scarce. In the conservatory just now are some fine specimens of *Solanum Psuedo-Capsicum*, about 3 feet in height and as much through, covered with their bright scarlet berries.

A. D.

THE WATER SHIELD.

In the many interesting collections of aquatic plants we have seen in the botanical and private gardens of this country we do not remember to have met with this curious and hardy North American plant. Its oval leaves are centrally attached to the foot-stalks, and are always noticeable and rather pretty as they float upon the water. They have their use as forming a shade and covert for fish, as anglers are well aware. The flowers are of a dull purple, and come to the surface to perfect themselves, but make little show. This aquatic plant has a remarkably wide distribution, it being found not only in North America, including the north-west coast, but in Japan, Australia, and India. Our figure, from the *American Agriculturist*, gives but a feeble notion of the plant.

THE AMATEUR'S GARDEN.*

COOL-HOUSE ORCHIDS AND FERNS.

YOUR article on Orchids, in THE GARDEN of December 20th, signed "J.," exactly suits my wants. I have a small greenhouse, 15 feet by 10 feet, now occupied with a few Heaths, Chrysanthemums, and other little flowers, which look pretty enough; but a collection of Orchids and Ferns, such as you describe, must be far preferable. It is heated by a flue under the floor, with iron grates to admit the heat; has a west aspect; three sides glass, and stone wall at the back, and is about 6 feet high in front and about 10 or 12 at the back. In such a house, will you kindly suggest how to make a rockery, what soil to put in amongst the stones (as I am as fond of Ferns almost as Orchids), and where I can obtain some plants of suitable kinds of each at a small cost? I see you give the names of some Orchids, will you please tell me which are the best for one to begin with, and also give me the names of some half-hardy exotic Ferns? In fact, I have little knowledge about such plants, but I am very anxious to have some, so any hints you may give me will be most thankfully accepted.

Derby.

R. H.

[Upon submitting your letter to our correspondent, "J.," he has favoured us with the following reply:—As your house is heated by means of a flue, I imagine the atmosphere in it must be somewhat unsuited to the requirements of such moisture-loving plants as Ferns and Orchids; still, if you really like these plants better than any others, do not let that deter you from attempting their culture. A rockery will do much towards keeping the atmosphere humid, and a few flat pans of zinc or earthenware kept constantly full of water and placed on the flue itself will do the rest. As your back wall is 10 feet high, your rockery need not much exceed half that height, and should be formed of large rocks or boulders, these being the best, and, no doubt, plentiful in your locality. Arrange them as artistically as possible, taking care to leave holes or pockets for your plants, and fill up the interstices with smaller stones and good fresh soil as the work proceeds. If you can obtain Moss-covered boulders so much the better, as these look prettier than the bare stones, and their surface is more suitable for the roots of the Ferns and

Selaginellas. In arranging the stones, place them so that the water will drain inwards and not run off in front as is frequently the case. The soil best suited for Ferns is half loam and half peat, with the addition of some coarse well-washed river or road sand. The ordinary white sand commonly used is too fine for the purpose. Do not sift your compost, but break it up roughly into lumps, and fill in the pockets or interstices at the top of the rockery with this before planting, while the stones and rough soil below will act as drainage for Ferns; indeed, all plants, although they like moisture, soon succumb if there is any stagnant dampness at the roots. Having finished the rockery, proceed to plant it, the present being an excellent season for the operation. Many of the North American and Japanese Ferns do well in a moderate temperature, as also do our own species, and their, in many cases, beautifully crested or tasseled varieties. The following are nearly hardy, and will suit your purpose: *Osmunda cinnamomea*, *O. regalis*, *Lastræa atrata*, *Polypodium cambricum*, *P. appendiculatum*, *Athyrium Filix-fœmina*, and its many fine forms, *Scolopendrium vulgare* and its fine wavy or crested varieties, *Cyrtomium falcatum*, *C. caryotideum*, *Onoclea sensibilis*,

Nephrodium molle, *Polystichum mucronatum*, *P. Lonchitis*, *Lomaria chilensis*, and the Killarney Fern, *Trichomanes radicans*. The British Maiden-hair, *Adiantum Capillus-Veneris*, also does well in a moderate temperature. The names of other species and varieties equally suitable may be readily found in any trade list of Ferns, and I should think there are nurserymen in your neighbourhood who could supply plants of the above, or others, at a reasonable rate. The back wall of your house, if bare, should be covered with fresh vegetation, as this assists in keeping the air moist, as well as adding much to the appearance of any structure. The pretty little *Ficus (repens) stipulata* grows very freely and clings to the barest of walls without any support, especially if they are moistened once or twice a-day with the syringe; and common Ivy also grows well, and always has a fresh and cheerful appearance. The rocks can be planted with *Selaginella denticulata* or *S. hortensis*, and this will soon form a fresh

The Water Shield (*Brasenia peltata*).

green carpet to the gently arching Fern-fronds above. *Tradescantia zebrina* or *T. viridis* may also be used for the last-named purpose, and these form a nice fresh background for pots of Hyacinths, Crocuses, or other spring-flowers that do not require much heat and yet come fresher and more beautiful when protected in a cool house. The Orchids should be placed on a stage or bench in the front of the house, as they are then near the light and more convenient for watering and other cultural details. These benches may be made either of wood or slate, the latter being preferable; and, if covered with about half an inch of small Cannel coal, Derbyshire spar, or fine gravel, so much the better for the plants, as the stages will then absorb sufficient water to keep them continually moist. Begin with the commoner free-growing kinds first, and, if these succeed (as they will, if real interest is taken in them), others and rarer kinds can be added afterwards. The following are best for a beginner, or any others mentioned in our list, see p. 512, Vol. IV.:—*Odontoglossum grande*, *O. biconense*, *O. Uro-Skinneri*, *O. Alexandræ*, *Phajus grandifolia*, *Calanthe vestita*, *Dendrobium nobile*.—J., *Whalley Range*.]

* This department is written exclusively by amateurs distinguished for skill in various branches of gardening.

WORK FOR THE WEEK.

PRIVATE GARDENS.

Pines.—Many plants will now have started, some are starting, and others showing fruit, therefore great care and attention will be required in every stage of Pine-apple culture for the next six weeks, to be successful with the plants when in blossom, and with fruit that is up, in order to prevent any kind of abortion in the pips or the uneven swelling so easily produced at this season. There must be no check to, or attempt to drive or hurry on, those fruits that are in any stage of swelling. Nothing but time, patience, and persevering attention will succeed in kindly starting, blooming, and swelling Pines to perfection in the short and dark days of winter, and we must allow from two to four weeks longer for winter fruit, according to variety, to swell, than those that will start into fruit in February and March. If hurriedly forced, they will push up weak, long stalks, productive of weak and irregular blossoms and abortive and small fruit (with some pips swelled imperfectly), light in weight, black inside, and bearing overgrown crowns. From 65° to 70° should be maintained in the pits, with a genial humidity during night, according to the light and sun by day; the interior atmosphere and humidity being in proportion to the sun and light. For all growing succession-plants, maintain a kindly bottom and inside atmospheric heat, advancing it as the days lengthen, and light increases. Pot on plants in every stage that require it, never allowing their progress to be arrested for want of pot-room at any season of the year.

Vines.—Those started in December will now be breaking, and they should have air on all favourable opportunities; but the giving air to Vines during severe frosts in January and February requires much attention, especially if the weather is windy. A temperature of 60° during the night, and a rise to 75° in the day, when the Vines are in bloom, will keep all safe. Peel the rough bark off Vines lately pruned, and dress them with some strong composition, to keep mildew and insects in check. The following mixture is very efficient for the purpose, namely, 4 ounces of soft-soap and 6 ounces of sulphur to a gallon of water, and as much quicklime and clay as will bring the mixture to the consistency of thick paint. The water must be hot, so as to melt the soap; the other ingredients should be stirred in, and the mixture used when cold. When it is used for Peach or Nectarine trees, more water and clay must be added to it, as the young bark and flower-buds of these trees are liable to injury when it is used too strong. Home-made brushes of bast matting, tied on short pieces of stick, are quite good enough for painting the mixture on the trees, and, to make safe, every crevice must be filled up; and when the first coat is dried, a second application should be made on places missed in the first dressing. If the Vineries are heated by pipes with troughs in them, all the sulphur and lime of last year's dressing should be scraped or washed off, for fear of rusting the tender berries after the Vines are out of bloom. When the Vines are forced early, the outside border should be protected by some slightly fermenting materials, such as litter, or tree-leaves, and covered on the top with wooden shutters, tiles, tarpaulin, or glass sashes. Maintain a temperature of 65° at night in mild weather in houses where the fruit is set, ventilate moderately and principally in the earlier part of the day, and do not fire strongly in cold weather. Ventilate freely, but avoid cold currents in houses where the Grapes are in bloom. Thin the bunches when they have well set, leaving one on each lateral, and also the berries. Muscats require a higher temperature for setting them than Hamburgs do. Water the inside borders freely with tepid water, and mulch them with a thin layer of short manure. Stop the young shoots at two joints beyond the fruit, and rub off all superfluous shoots. Start succession houses, beginning with a night temperature of 45° or 50°, and syringe the rods daily until their bunches are formed; then desist, and maintain sufficient atmospheric moisture by spilling water on the floors and using evaporating troughs. In late houses, where the Grapes are incut, use a little fire-heat and ventilation at the same time, to preserve a dry atmosphere at about 45° and prevent mouldiness, which is very prevalent in dull and damp winters. Examine the hanging bunches weekly, and remove from them every mouldy berry, otherwise the disease will soon spread extensively. Prune and dress late Vines as soon as the fruit is cut from them, and swing the rods to cause them to break evenly at starting time.

Peaches and Nectarines.—Be cautious in the application of fire-heat in orchard-houses other than where the trees are in bloom, especially in dull weather. Where the trees are in flower, however, the night temperature may be kept at 55°, and throughout the day may be raised, with sun-heat, to 65° or 70°; but, at this stage, a free circulation of air amongst the plants is of the utmost importance. Assist the setting of the crop by dispersing the pollen with a camel-hair brush, a feather, or by shaking the trees a little. Cease

syringing the trees from the time they begin to expand till the fruit has set; but, at the same time, continue to maintain a little moisture in the atmosphere, by sprinkling the floors daily with water. Disbud sparingly at first, removing only evidently superfluous growths. In starting Peaches and Nectarines, begin with a low temperature, say 40° at night; syringe with tepid water, and keep up a moist atmosphere by sprinkling the floors with water. See, also, that the borders are thoroughly damp to the bottom; and, in order to accomplish this, they must be well soaked before forcing begins. Prune the trees in the later houses, paint them with a prepared mixture, tie them up to the trellises, and freely ventilate the houses night and day. If the borders require renovating, they should be attended to in that respect whilst the trees are in a dormant condition, removing most of the old surface-soil, and replacing it with good fresh turfy calcareous loam.

Figs.—See that the borders in which the trees are growing are thoroughly moistened to the bottom, and begin forcing with a temperature of 50° at night, syringing the trees freely with tepid water, and maintaining a moist atmosphere. As the trees begin to grow, gradually increase the temperature, and rigidly attend to stopping the shoots at the third or fourth joint by squeezing the points. For starting pot Figs, no heat is so genial as that contributed by fermenting manure, and for this purpose a bed of manure inside the pits, and in which the pots could be plunged so as to have a bottom-heat of 75° or 80°, is of material benefit to the plants. Attend to re-potting plants requiring shifting, and mulch over the surface of the soil in the pots with horse-droppings, or other short and rich manure.

Cherries.—When Cherries are forced early, the temperature must be kept low, never allowing it to rise above 50° at night, until the fruit is set. When they are in flower, the temperature may be raised a little, and a little fire-heat and ventilation given at the same time.

Strawberries.—For early forcing, plants with good plump crowns ought to be selected; and those potted in rather small pots, with good matted roots, always set their fruit the best. Introduce them, according to demand, space, and convenience for forcing them, into a pit, Peach-house, or Vinery, having at first a temperature of 45° to 50° at night, and keep them on shelves near the glass. If in a pit, a little bottom-heat, about 60°, tends to produce abundance of roots. When they are in bloom, and when the fruit is set, increase the temperature about 10°, and always keep them in airy positions, and well attended to as regards watering.

Melons.—Sow some early Melons in small pots plunged in the Cucumber-house; the Scarlet Gem and Egyptian Green-flesh are good flavoured and early sorts, and may be successfully grown in boxes in a Pine-stove. Prepare beds or pits for their reception, and plant them out before they get pot-bound. Should fermenting material be the heating agency, see that it has been well turned and sweetened, and that it is uniformly moist and not heating too violently.

Cucumbers.—At this time, Cucumber plants are frequently infested by thrips and red spider, so that repeated fumigations must be resorted to, as well as syringings, to keep them down. A sowing of both Cucumber and Melon seed ought now to be made for succession crops. Maintain a night temperature of about 70° in bearing pits, and rather than use too much fire-heat in cold nights, cover the glass, if practicable, with mats. Avoid over-cropping, and keep up a healthy supply of wood and leaves, which thin a little to prevent over-crowding. Ventilate in fine weather sufficiently to dry the leaves once a day, and water moderately with tepid water.

VEGETABLE FORCING.

Asparagus.—Continue to cut all shoots as they attain a length of about 6 or 8 inches, and, if the soil gets dry, gently sprinkle it with tepid water. If necessary, make up another bed for succession. These beds may be formed of dung or leaves above the ground, or trenches may be cast out about 2½ feet deep, and as wide as the frames, and filled with the fermenting materials, the frame being set on a level with the ground, and a lining of hot dung built all round it. A few inches deep of light soil should then be placed inside to plant the roots in. Cover over the roots sparingly with light mould, and keep all pretty close until the Asparagus begins to grow, when a little ventilation greatly improves the quality of the "grass." Those who prefer blanched Asparagus should darken the frames by a covering of mats or litter, but in all cases be particular that neither the bottom nor top-heat rises above 70°, whilst 5° or 10° less is much more conducive to the well-being of the plants.

Carrots.—Sow some of the early Horn on a slight hot-bed, together with Lettuces, and keep those previously sown dry and clean.

Celery.—Sow a small quantity of some good, solid-stalked, early

sort, in a pan of light rich earth, in a hot-bed or pit, for the earliest crop.

Chicory and Dandelion.—Introduce roots of these into the Mushroom-house, arches under Cucumber-beds, under boxes in Vineries, Pine-stoves, or, in fact, any place where they may be kept dark and in a temperature of about 60°.

Endive.—Lift some plants of these with good balls and plant them in frames, where, as soon as they have grown enough, cover them with pots or boxes to blanch. A few seeds may be sown in the event of very early Endive being required.

French Beans.—Make successional sowings of these in pots half filled with rich loamy soil, and grow them in front shelves in the forcing houses, or in pits built expressly for them. Earth them up before they begin to flower, and syringe them regularly to keep red spider in check. Newington Wonder, Syon House, Fulmer's Forcing, and Osborn's, are good sorts for forcing.

Lettuces.—Young plants of these in frames should have the sashes tilted at back and front, in favourable weather, if wet; but if dry, they should be removed entirely throughout the day, and replaced at night. Tie up a few old plants of the Brown Cos, as required.

Mint, Pennyroyal, and Tarragon.—Plant some roots of these in boxes or pots, using light soil, and introduce them into some heated house or pit. A portion of a hot-bed may be devoted to them.

Mushrooms.—Maintain an atmospheric temperature of 55° or 60°, and gently charge it with humidity; the beds may rise 5° above the heat of the house. Attend to the prevention of draughts in the houses, as they are productive of severe checks to the crop. Obtain some fresh horse-droppings, as free from strawy litter as possible, for the succession beds. It is a good plan to turn and prepare this material in winter on the floor of the Mushroom-house, a practice that produces, by gentle fermentation, just the natural, gentle ammonia-charged atmosphere, in which the Mushroom luxuriates.

Mustard and Cress.—Sow these, in boxes or patches, in moderate heat, weekly or fortnightly, as required.

Onions.—Sow some of the Tripoli variety in a slightly heated frame, for drawing whilst young, for salading, or for transplanting.

Potatoes.—Plant some of the Early Ashleaf sort in gently-heated frames, and sow some Radishes on the surface of the soil. Ventilate on favourable occasions, and do not over-water.

Rhubarb and Seakale.—Lift some roots every three weeks, and introduce them into the Mushroom-house, or other heated structure. Some crowns may also be covered, where they are growing, with pots, over which place some litter or leaves. To blanch it, the Seakale should always be kept dark.

Tomatoes.—Sow a few seeds of these, if early plants are required.

ARCHITECTS VERSUS LANDSCAPE GARDENERS.

I BEG to thank Mr. Niven (see p. 25) for his timely and excellent reply to "Civis" (see p. 21), whose strictures on landscape gardeners show in what light they are held by architects. Admitting, as "Civis" has stated, that some landscape gardeners, like many architects, do trespass upon the domain of their professional rivals in creative art, is that any proof that either or both are wrong? I trow not. In the battle of life every man does the best he can for himself, and whether the percentage-paid architect, or the premium-paid landscape gardener, is the most worthy of the confidence of employers, is for the latter to decide. Taking the three heads, heating, ventilation, and sanitary arrangements, architects, if not ill-informed, are certainly very unfortunate in their practice; for, to meet with a place which is in any way perfect in these respects, is the exception rather than the rule. Go again to farm buildings. Gentlemen, whose whole lives have been devoted to rural occupations, must, as a rule, be better informed than those who have necessarily nothing but a theoretical knowledge in such matters. In fact, if the architect insists upon drawing a hard and fast line of demarcation, I see nothing for it but that he must confine himself to the mansion and its surroundings, and that the landscape gardener must be content with outdoor ornamentation. I grant that the architect should have a voice in the formation of terrace gardens, the landscape gardener watching that he does not convert them, as is customary with some, into stone-yards; but, beyond that the architect has no right to go. "Civis," however, would doubtless grasp at every part of an estate, and would, no doubt, feel himself quite competent to furnish designs for plant and fruit houses, though he might be ignorant of the names, habits, or peculiarities of the plants

intended to occupy them. Of course, architects, in their own estimation, are well up in such matters; but, judged from a practical point of view, hot-houses and architectural conservatories are found unsuitable for the purposes intended; and it is the same with farm homestead arrangements. Therefore, how practical men do wrong in accepting employment which they understand, I cannot imagine. Indeed, we gardeners, in matters of taste, can hold our own; and, though we do not wish to inaugurate an aggressive warfare, we are prepared to defend our position if assailed. Among the original architectural thinkers of the last half-century, the late J. C. Loudon cannot pass without remark; while the bold conception of Paxton, in the exhibition building of 1851, shook both architecture and engineering to its centre, and has been the land-mark of progress ever since. Go we then to Mentmore, Baron Rothschild's beautiful residence in Buckinghamshire; to the château of another of the Rothschilds, near Paris; to his bijou and exquisitely-finished villa in the garden at Chatsworth; to the model village at Edensor; and to scores of improvements upon the Duke of Devonshire's property in all parts of the country, and we have proof that a man may have originality of conception in a line of life to which he was not brought up, and develop it so as to command the admiration of the world. This Sir Joseph Paxton did; and scores of others, with the same appliances, could do the same; but some men strive hard for a niche in the temple of fame, while others have greatness thrust upon them. Therefore, let not "Civis" and others imagine that they are unrivalled. The leading landscape and horticultural architects are in a position to hold their own, even against architects themselves; and there are not a few of the latter, who make it a rule, wherever they go, to open a feud with the landscape gardener, if not with the ordinary gardener employed on the place. X. P. Y.

THE NEW SUBSTITUTE FOR COAL.

WE (*Galignani*) stated a short time ago that a Belgian peasant had made the extraordinary discovery that earth, coal, and soda, mixed together, would burn as well and better than any other combustible, and the fact has since been proved beyond a doubt. The way in which he found this out is curious:—He had been scraping the floor of his cellar with a shovel, in order to bring all the pieces of coal lying about into a heap, which, mixed as it was with earth and other impurities, he put into his stove. To his astonishment, he found that this accidental compound burnt better instead of worse than he expected, and emitted much greater heat. Being an intelligent man, he endeavoured to discover the cause, and discovered that a good deal of soda, probably the remnant of the last wash, lay about the floor of the cellar, and that some of it must have got into his heap. He then made a few experiments, and at length improved his compound sufficiently to render it practical. The publicity given in Belgium to this discovery caused trials to be made everywhere, and it has now been ascertained that three parts of earth and one of coal-dust, watered with a concentrated solution of soda, will burn well and emit great heat. Many Parisian papers talked of it, but only one—the *Moniteur*—went so far as to make the experiment at its printing office. A certain quantity of friable and slightly sandy earth was mixed with the quantum of coal-dust prescribed; the two ingredients were well incorporated with each other, and then made into a paste with the solution above mentioned. The fire-place of one of the boilers had been previously lighted with coal, and the fire was kept up with shovelful of the mixture. The latter, in a few seconds, was transferred into a dry brown crust, which soon afterwards became red-hot, and then burnt brightly, but without being very rapidly consumed. The fact of the combustion is, therefore, well ascertained; but before the system can be universally adopted, there are some important points to be considered, such as the calorific power of the mixture compared to that of pure coal, its price, and, above all, a remedy for the great drawback attaching to it—its fouling the fire-grate considerably.

Lightning Rods.—The *Journal of the Franklin Institute* has published a series of articles by Mr. John M. Mott on lightning. The writer comes to the following among other conclusions:—"Lightning rods, as usually erected, do not afford much protection." "The conducting power of lightning rods is proportional to their solid contents, and not to their surfaces." "Insulators are of no use in any case." "The rod must be attached directly to the building, the closer the better." "Sharp points for the upper terminations of rod are necessary; rods are of but little value without them."

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE LION'S TAIL.

(*LEONOTIS LEONURUS.*)

THIS is one of the representatives of the Labiate family, from the Cape of Good Hope, and one that is rarely met with in cultivation, much rarer, indeed, than its peculiar merits deserve. Its introduction into Britain dates back for considerably over a century, and in some of our old works it is alluded to as a subject of pretty general cultivation; in fact, it is one of our old friends that ought not to be lost sight of. What, then, are its special claims? and what are the reasons why it has passed into this state of neglect? As to claims: when I say that its flowers and flower-buds, including the smaller bracts, are of an intense orange scarlet, and that these, in a well-grown plant, rise tier above tier, interspersed here and there with a sprinkling of narrow leaves, to a height of 2 feet or more, it will be obvious that its colour alone is a strong recommendation in its favour, added to which, it possesses a nice branching habit of growth, the lower part of the plant being clothed with leaves of an exceedingly delicate tint of green, and, like many of the Labiate group, the whole plant yields an agreeable aromatic odour. Why, then, seeing that it has such claims, is it rarely met with in the gardens of this country? So rarely, indeed, that few of the present generation of gardeners are aware of its existence. In replying to this inquiry we must study its peculiar constitutional characteristics, and in these, if I mistake not, we will obtain a solution of the mystery. As has just been stated, the Lion's Tail is a Cape plant, or rather, is indigenous to a district some 150 miles north of the Cape, consequently, it is not sufficiently hardy to stand our climate during the winter, even supplemented by the protection of a cold frame; possibly this statement should be modified as to the extreme south of England, but of its growth in such localities I have had no experience. We must, I think, look upon this plant as essentially a tender greenhouse-loving plant during winter, in fact, one that should be favoured with a similar treatment to what the great majority of our tender bedding-plants require. As the beauty of the *Leonotis* chiefly rests in its brilliant flowers, rendered all the more beautiful by their abundant production, I must say a word or two on the circumstances most conducive to the attainment of this result. With our ordinary bedding-plants, cuttings struck in autumn and potted off in spring are eligible for flower-garden decoration the following summer, but to this rule the Lion's Tail forms quite an exception. Under such treatment the result would be an abundant growth, culminating late in autumn into a vigorous character, and exactly in proportion to its vigour, the more susceptible of injury from early autumnal frosts would it be, but not a single flower, nor even the sign of one, would make its appearance. How, then, is the all-important result to be attained? Merely by giving the plants

a preliminary growth for a twelve-month in 7 or 8-inch pots, under exactly similar treatment as regards liquid-manure and exposure as we give to our *Chrysanthemums*; then wintering them in the greenhouse in a comparatively dry and quiescent condition, exciting them to make a moderately free growth in the spring, gradually hardening them off, and ultimately planting them out in the middle of May. In this operation judgment is necessary, as, if the soil in which they are to be planted is of a heavy character, it will be better to plunge than to plant; but, if of a light sandy nature, plant out; but do not, under any circumstances, disturb the pot-bound ball of roots; leave the rest to a bright summer's sunshine, and I will warrant the result will far more than counterbalance the extra trouble in obtaining it. My first acquaintance with this plant was

made some twenty-five years ago at Kew, where an old plant, that had stood sponsor for a label (if I may use a somewhat left-handed expression) for a number of years, was consigned to my care, with a lot of other Cape and New Zealand plants, to utilise on a considerable extent of wall and wall-borders we had just then acquired; and the said old plant, after the somewhat rough surgical operation of cutting the potsherd portion of the ball off square with the spade, and planting it at the foot of the wall, was one of the most brilliant plants during the autumn, only rivalled by the now familiar *Tritoma Uvaria*, which then, and under similar circumstances, minus the surgical part just alluded to, for the first time obtained its true status in English gardens. The roots of the latter were amenable to some reasonable disentanglement, which resulted in a vigorous growth, and an equally vigorous floral display, whereas those of the former were so matted together as to defy separation, and, in my opinion, to this very fact we were indebted for the satisfactory result; hence, my advice as to the non-disturbance of the ball in the process of planting out. Why the term "Lion's Ear," as indicated by its generic title of *Leonotis*, or "Lion's Tail," as its specific title *Leonurus* would imply, has been given to this plant, was, I well remember at the somewhat remote time I speak of, a mystery to me, and, I must admit, it is so still. The genus is closely allied to *Phlomis*, to which it was originally referred by old botanists. Cuttings strike freely in spring, in a slight bottom-heat, by merely removing the young shoots from a growing plant, much more so than they do in the

The Lion's Tail.

autumn, and will be found to answer all purposes for the mode of culture I have already described. The subject of our notice is common in most Continental gardens, where its flower-producing properties are naturally developed, whereas, in our moist climate, we must have resort to such artificial means as experience and practice may dictate.

Botanic Gardens, Hull.

JAS. C. NIVEN.

[This very fine plant deserves to be more frequently grown in our gardens. In warm light soils, in the southern parts of the country, we have observed it thrive well, grown as Mr. Niven advises; and, in districts where it would not bloom out of doors, it is well worthy of a place as a cool greenhouse plant. About Paris, established plants placed out for the summer flower profusely. Wherever it can be grown well in the open air, it would form a valuable plant for association with the finer bedding and sub-tropical plants.]

NOTES OF THE WEEK.

— MESSRS. BARR & SUGDEN have received, from India, a large consignment of the very fine *Lilium Wallichianum*, which is the best of the longiflorum section, and is very rare in this country.

— THE famous collection of plants, long grown by our able correspondent, Mr. Baines, formerly at Bowden and now at Southgate, is to be sold by auction at Stevens's in April.

— Two or three species of *Ferula*, on account of their freshly-tinted and fine feathery foliage, are still interesting objects in the herbaceous grounds at Kew.

— MR. WILLIAM BULL has a fine golden-flowered *Odontoglossum*, in the way of *O. triumphans*, now in blossom. It bears great, branched, many-flowered spikes, fully a yard long, the blossoms being from 2 to 3 inches across, and very striking in appearance.

— WE have received from Mr. G. F. Wilson, F.R.S., a pamphlet, "The Royal Horticultural Society; as it is and as it might be." This is published by Mr. T. S. Gilbert, of Moorgate Street. We shall allude to it at greater length next week. We may, however, state at once that it embodies the views, as regards the future of the Society, for which Mr. Wilson has lately so ably contended.

— THE Count d'Esterno advocates the destruction of woodpeckers on the ground that they injure trees, by boring after insects, more than the insects themselves do. In this opinion he is opposed by Dr. Turrel. M. Carrière seems perplexed by the disagreement of such high authorities, and asks the question whether it has been plainly proved that woodpeckers never bore into trees which contain no insects. Our own conviction is that the instinct of the woodpecker in its search for food does not mislead it into the useless labour of boring into sound trees.

— THE Count de Lambertye has recently published an interesting brochure of 128 pages, the subject of which is the history of the Strawberry from the sixteenth century down to the present time. The Count has evidently entered into his work *con amore*, and has aptly divided his pages into three sections, the first containing a general account of the genus, with descriptions of some of the most important varieties. The second part is occupied with historical notes on the different modes of culture which have been employed from the year 1570 down to 1873; while the concluding pages are devoted to an exhaustive account of the most approved methods of Strawberry culture, as at present practised in France. The work is published, at a franc, by A. Goin, 62, Rue des Ecoles, Paris.

— A GENERAL meeting of the Linnæan Society of London was held on Thursday evening, Jan. 15, in the new Government rooms, at Burlington House, when certain very important alterations in the bye-laws, recently made by a majority of the council of the society were discussed. These consisted of a repeal of those bye-laws which prevent fellows from holding any paid offices in the society, and provide for the election of the paid librarian (who, of course, is not a fellow) by the society at large, and of a proposal to place all appointments to salaried posts entirely in the hands of the council. Unfortunately, no special notice of these proposed changes had been sent to the fellows, or, as they are distasteful to many, there would have been a larger gathering than the sixty-six who voted upon the question. A majority of two-thirds is required to pass alterations in the bye-laws, and this number exactly, forty-four, voted for the council's alterations. The result is, that by the barest possible majority changes have been made in the constitution of the society which, in the opinion of many of its fellows, must very seriously lower its hitherto high character, and will place undue and excessive power in the hands of the council.

— At a meeting of the Royal Horticultural Society, which took place on Wednesday last, two dozen beautiful pots of Lily of the Valley were shown by Messrs Standish & Co., of Ascot. There were also a few red and white-flowered Chinese Primulas of a good "strain" from Messrs. Dobson & Son, of Isleworth; a *Cineraria*, with large showy violet-purple flowers, from G. F. Wilson, Esq.; *Odontoglossum angustatum* from Mr. W. Deaning; and a specimen of *Cypripedium Roezlii*, to which a first-class certificate was awarded, from Messrs. Veitch & Sons; from Mr. R. Dean, Ealing, came some plants of White Swan bedding Viola, and, also, a few Primroses, beautifully bloomed, including Rosy Morn, Yellow Queen, and Violet Gem; Mr. Wm. Paul, Waltham Cross, exhibited some very fine cut flowers of Camellias; and Mr. Bennet, of Hatfield, furnished some very fine Early Prolific Tomatoes, ripe Guavas, and the edible fruits of the *Tacsonia Van Volxemii*; Messrs. Masters & Kinmont, Canterbury, sent a dish of pretty little seedling Apples, named Duchess of Edinburgh, a cross between Court of Wick and King of the Pippins; and from Mr. Wm. Hocley, Toddington, Beds., came another handsome seedling Apple; Mr. R. Dean, exhibited a dish of Brownell's Vermont Beauty Potatoes, a red-coloured, large, flattish variety, and Extra Early Ver-

mont, a white sort, said to be a fortnight earlier than the American Rose.

— HARDY Cyclamens are finely in flower in the neighbourhood of London. In Mr. Wilson's garden, at Weybridge Heath, *C. Coum venum*, and *C. Atkinsii* are now beautifully in bloom.

— A MEETING was held at Bath the other day, under the presidency of the Mayor, to consider the project of a winter garden for that city. All present were unanimous in favour of its erection according to plans then shown, and advised that subscriptions should be solicited for that purpose.

— MESSRS. HOOPER, of the Central Row, Covent Garden, who pay much attention to dried Grasses and everlasting flowers, have sent us a specimen of some ornamental Grasses prepared in a new way. Instead of being dyed, as now so common, they are slightly bleached, as described by M. Wermig in our columns (see p. 419, Vol. IV.). This gives them a charmingly silvery appearance. They are the best things we have seen in the way of ornamental Grasses in the market.

— WE observe a discussion in the *Irish Farmers' Gazette* on the respective merits of the eastern and western Planes as trees for town planting. We regret to learn that the former species has been selected for planting in Sackville Street. The Planes in the London parks and squares, as well as those planted along the Thames Embankment, are all varieties of the western Plane (*Platanus occidentalis*). This we have on the authority of Mr. Gordon, who certainly knows more about the trees in question than the now old authorities, who once condemned the western Plane for London planting.

— THE second part of the "Flora of British India," which is being prepared at Kew, under the supervision of Dr. Hooker, is, we understand, ready for publication. This important undertaking is likely to occupy the attention of the botanists engaged upon it for some years to come. It involves the critical examination and description of the whole of the flowering plants of our Indian possessions, numbering some thirteen to fourteen thousand distinct species. The new instalment continues the Polygalaceæ, and proceeds as far as the Geraniaceæ.

— THAT doctors differ is well illustrated by a little discussion now going on in *Nature* between two gentleman well-known in the gardening and botanical world. Mr. Berkeley says—"In *Nature*, vol. ix., p. 161, it is stated by Mr. Worthington G. Smith that the bodies referred to by Dr. Montague to Artotrogus are possibly no other than *Volutella ciliata*. Nothing can be more common on decaying Potatoes than *V. ciliata*, but I can state most positively that Montague's Fungus, whatever its nature may really be, had nothing to do with *V. ciliata*. A reference to the figures in the *Journal of the Horticultural Society* (vol. i., tab. 4, figs. 27, 28, 29), and the characters of Artotrogus, apart from the specimens submitted to myself, and the occurrence within the cellular tissue, ought to be quite sufficient."

— MR. DOUBLEDAY, of Epping, reminds us that in the list of mild winters given last week (see p. 50), mention is made of the winter of 1846-47, which was a very severe one. December, he says, was very cold. On the 14th, the thermometer, 4 feet above the ground, indicated 15° of frost at 8 o'clock a.m., on the 15th, 17°; on the 18th and 31st, 19°; and there were only five or six days on which the temperature was above the freezing point at 8 o'clock a.m. January and February were also very cold. On the 10th of February the temperature on the ground was 7½°. The date, he suspects, is a misprint for 1845-46, which was a very mild winter. In January, 1846, the thermometer was only twice below the freezing point at 8 o'clock a.m., and four times in February. On the 24th, the maximum in the shade was 58°. Mr. Doubleday adds that he gathered some ripe British Queen Strawberries from the open ground the last week in May, 1846.

— MR. EASTLAKE has (says the *Pall Mall Gazette*) very opportunely called attention to the fact that the chapel of the old town-house of the Bishops of Ely—the house in Holborn, the Strawberries in whose gardens Shakspeare has made famous—is about to be sold by auction. For some time past it has been used as a Welsh church; why the Britons have to give up their right in it is not explained. Though the chapel alone of the ancient house is left, it is, like Northumberland House, also soon to vanish—a trace of a past state of things. It is a trace of the days when the suburb between the cities of London and Westminster was largely filled up by the houses and gardens of earls, bishops, and other great men, who, then as now, needed a dwelling-place when they came to attend Courts and Parliaments. The Bishop of Ely's house in Holborn, with its gardens and fields, in the days of its grandeur, covered twenty acres. The estate was first given to the see by William de Luda, bishop from 1290 to 1297. John Hotham, bishop from 1316 to 1336, famous for rebuilding the presbytery of his cathedral after the fall of the great tower, gave his convent of Ely a "fair Vineyard in Holborn, a suburb of London."

THE FRUIT GARDEN.

GRAPE-GROWING AT MESSRS. LANES'.

OUT of the Berkhempestead Nurseries have come, of late years, some of the best collections of Grapes exhibited at our metropolitan and provincial shows. Through cultural skill, good and substantial soil, and abundance of water, the Vines under Messrs. Lanes' care grow strongly and bear freely, producing both heavy crops and large bunches. Their principal Vinery is a spacious span-roofed structure, 135 feet long and 25 feet wide, glazed with large panes, and heated with two rows of 4-inch hot-water pipes, that surround the house inside. It is built on the side of a gentle slope; the Vines are planted on the sunny side only, and are trained under the span, down to the upright sashes on the other side. It is now twenty years since this structure was erected in the form of a span-roofed glazed shed, open at the sides, and supported on wooden posts, for the purpose of protecting fruit-trees in pots, choice Conifers, Roses, and a few other plants, in winter. At that time there was no intention of converting it into a Vinery; it was, however, thought expedient to plant Vines against the posts and to train them inside, so that they might afford shade in summer, and, perhaps, a few Grapes for Messrs. Lanes' table. No border, in the ordinary sense of the term, was made, but, at planting-time, a little mound of prepared soil, consisting of chopped turfy loam from the common and decayed manure, was got together for each Vine, and, after a year or two, the interval between the mounds was filled with a similarly prepared compost. The Vines, after being planted, made such excellent progress that it was thought the house would be improved if the upright sides were glazed, and if it was made entirely a Vinery; accordingly it was enclosed, and the result is one of the most fruitful Vineries in the country. The Vines were originally planted about 3 feet apart, but it was subsequently found necessary to thin out a few of them in order to give those left more room; therefore, they now stand at distances of from 3 to 6 feet apart. They are all pruned on the close-spurred principle, each Vine being confined to a single rod; yet, notwithstanding the severe pruning to which they are annually subjected, they are in the best of health and vigour, and have formed trunks from $2\frac{1}{2}$ to $3\frac{1}{2}$ inches in diameter. A great many varieties are grown in this house, and amongst them the following are the most noteworthy, viz.:—Black Hamburgh, Foster's Seedling, and Royal Ascot; these three ripening earliest, the last being a very early kind, and one which has small bunches of beautifully coloured and well-bloomed berries. The Buckland Sweetwater and Muscat Hamburgh succeed these, the remaining kinds being West's St. Peter's, Trebbiano, Madresfield Court, Pope's Hamburgh, Frankenthal, Mill Hill Hamburgh (which produces berries of very large size, the surface of which has the appearance of being hammered), Lady Downes, Barbarossa (a gross grower and great

bearer, producing very large bunches), Mrs. Pince, Golden Champion, Alicante, Gros Colman, and several others. This Vinery is also used as a trial-place for all new sorts of Grape Vines, which are inarched on the side-shoots that rise from near the root. Should the variety prove good, it is retained; but, if it turns out inferior, after a fair trial, it is removed and discarded. Here the Muscat Hamburgh is held in high estimation. In one instance it is grown on its own roots; and, in other cases, it has been grafted on the Trentham Black and Morocco; but none of these stocks seems to have any influence over the scion—all grow equally well, and set and ripen heavy crops of fruit, each cluster weighing from 1 to 4 lb. Neither the Golden Champion nor the Madresfield Court Grapes do well at Berkhempestead, the berries of the former invariably spotting, and those of the latter cracking and becoming mouldy before they are ripe. Messrs. Lane, however, consider these two sorts to be excellent under special cultivation and care. In this Vinery Peach-trees are wintered; Figs and Vines in pots are plunged in sawdust. Another span-roofed house of the same description, and running up and down hill like the last, but situated farther up the slope, is also devoted to Grape culture, and is divided into three compartments, each 45 feet long. The compartment farthest up the hill is filled with late-fruited Vines, such as Alicante, Lady Downes, Mrs. Pince, Trebbiano, and two plants of Black Hamburgh. The second division contains Hamburghs only, and the third includes the Muscat of Alexandria and Bowood Muscat; it is from this latter division that the fine bunch of Muscat of Alexandria Grapes, of which we give an illustration, was cut. The divisions are in the form of terraces, one a little higher than the other, and are ventilated on a simple and effective principle. The whole of the side-sashes of each compartment are opened on the lever-and-rod system at the same time; but, in the event of all not being required open at the same time, those wanted to be kept shut may be unfastened from the rod by merely unhooking the little chain that binds them to it. Top ventilation is furnished

Fine Bunch of Muscat of Alexandria Grapes.

on the same principle, but, in this case, the ventilators are only in every alternate sash, and a rope is used to open and shut them instead of an iron rod. The rain-water from the roof is collected in cement-lined sunk tanks in the several compartments, but, when rain-water fails, ordinary water is pumped into them. Water here is plentiful, there being many hill-side springs, one of which runs continually summer and winter, close to the Vineries, and it never varies in temperature beyond a degree or so, the usual temperature being 51° or 52° . By digging into the ground to a depth of about 2 or 3 feet, in any part of the home nursery, water is sure to be reached, and to this is attributed, to some extent, the excellence of the Berkhempestead Grapes. At the lower ends of both the ranges of Vineries to which we have just adverted, the Vines produce by far the finest Grapes and the heaviest bunches, a circumstance attributable to the additional

light afforded by the gable ends of the house, and to the enlarged supply of water that must necessarily percolate down hill to that portion of the border. As regards the formation of Vine borders, Messrs. Lane consider that sometimes needless attention is paid to that matter. They are of opinion, however, that all borders should be on a well-drained sub-stratum, and that they should be composed at first of some substantial open soil for a space of 8 or 10 feet wide. The Vine roots in their large Vinery extend far out into the nursery; but, in the last-erected range, the Vines in which are only six years old, a 4-feet wide inside-border has been made, and to this, and a narrow outside border, their roots are confined, for the convenience of early forcing. When they require more nourishment, it will be given in the shape of additions to the outside border. The soil used both for borders and also for Vines in pots, is the surface turves off Berkhempestead Common, which consist of a strong, very fibrous, yellow loam, not too tenacious, chopped roughly and mixed with some well-decayed manure. That Vines may be successfully grown for a long time in a comparatively small bulk of soil, is exemplified here in a little span-roofed house, which is now being entirely cleared out, to make room for growing pot Vines, for which there is always a great demand. Along both sides of this house, next the walls, were built brick pits, 3 feet deep and 20 inches wide, somewhat similar to what we occasionally see Melons grown in. A foot deep, beyond the measurement of the box-like pits just spoken of, had been filled with brickbats, over which the rest of the space was filled with the already mentioned soil. A Vine was then planted to every 4-feet-wide sash ten years ago, and ever since has borne good crops of well-coloured fruit. Pot Vines were formerly grown in this house, but as the swelling and ripening fruit required a drier atmosphere than that for young Vines, the latter had to be removed. Of pot Vines there are over 2,000 saleable plants grown here every season, besides a large number for permanent transplantation, as well as some fruiting specimen plants. The latter are mostly all grown in No. 1 pots, which is the largest size; they consist of Foster's Seedling, Black Hamburgh, and Alicante, which are considered to be the best sorts for pot culture. The Madresfield Court Grape, too, was tried here last year, as a pot Vine, and was found to succeed. In the growth of pot Vines the main point of success consists in the early and thorough ripening of the wood. When the specimens here are started into growth, the rods are trained along the rafters of the houses like those of permanent Vines, and treated accordingly. When the Grapes are ripe, the rods are trained around a trellis fixed to the pots, or some strong stakes are inserted in the soil in the pots. In this way each Vine will produce from two to four dozen bunches of fruit, averaging nearly $\frac{3}{4}$ lb.

The Nurseries.

These nurseries, which consist of upwards of a hundred acres, have long been famous for Grapes, Roses, Azaleas, Rhododendrons, Ivies, Conifers, fruit trees, and other plants equally interesting. In that portion of them which lies high, on the breezy Berkhempestead Common, Cypresses and other Conifers grow with wonderful luxuriance, and even such peat-loving plants as Rhododendrons bloom beautifully here, and succeed satisfactorily where not a particle of peat exists. This is greatly in their favour, for when they are moved to sheltered places, where they can have a little peat, they take to their new situations at once, thus obviating all risk of failure. The Rhododendrons, of which some 5,000 to 10,000 are raised in these nurseries every year, are now as thickly set with flower-buds as they possibly can be, and the wood being hard and solid, even the finest hybrids winter safely. Laurels are grown here by the acre in the form of bushes and standards, but preference is given to the variety called *caucasica*, as it grows into a dense pyramidal form, finishes growing and ripens its wood early, whereas the common Bay, which it most resembles, continues to grow late in the season. Wellingtonias, too, are grown here in thousands, and pretty little plants they are, densely furnished with branches to the very ground, and averaging in height from a few inches to 8 feet; after they attain a height of 4 feet many of them become laden with cones. We noticed a large bed containing a great variety of

seedling variegated Yews, raised from one batch of seed, and embracing the habits of the English, Irish, and intervening types, the variegation being mostly golden. Amongst Pinuses *P. Nordmanniana* is the most remarkable; indeed, we never remember having seen so many of these fine trees growing together at one place; there are literally thousands of them, varying from a foot to 11 feet in height. *Cupressus Lawsoniana* may also be counted by thousands, of all sizes, the largest being symmetrical well-furnished specimens. Of *Thujaopsis dolabrata* we observed a large plantation raised from seeds saved in these nurseries, but, perhaps, the most attractive plant in the ground was *Cryptomeria elegans*, of which there is a large quarter containing young trees from 1 to over 4 feet in height. These beautiful little Conifers assume a bronzy hue in winter, but regain their fresh green appearance in spring, and, than these, few plants are better adapted for centres to flower beds. Amongst other Coniferous plants those of *Araucaria imbricata* were the most remarkable. Of these there are thousands, varying from young seedlings to plants 12 feet in height, all densely furnished with branches to the very ground. These consist chiefly of a strong dense-growing variety of this tree, many of which have borne and some are now bearing cones. Two of these *Araucarias*, each about 8 feet high, ripened seeds last year. These were saved, and sown in boxes of light soil, set in cold frames, and, notwithstanding their number being much reduced by mice—who are particularly fond of *Araucaria* seeds, 200 of them were left untouched, and these have produced as many healthy young plants. Ivies are largely grown here in pots, some as specimens, others in every stage between that and the cutting form. The specimens of them are trained on sharply attenuated pyramidal trellises, and are chiefly grown for purposes of exhibition, for which *Caenwoodiana*, *maculata*, *albo-lutescens*, *canariensis latifolia*, *maculata*, *argentea rubra*, *gold-blotched*, *himalaica*, *argentea*, *rhomboida obovata*, *digitata*, and the Irish Ivy, are the best suited. For house decoration, nothing is more useful or ornamental than Ivies, especially in winter, and in order to meet the demand for them, several ranges of pits are filled with small plants of them in 60-sized pots; therefore, when a window-box is to be filled, or a suspended basket to be made up, a few of these young plants are turned out of their pots, planted as required, and their shoots, that formerly were stiffly tied to stakes, are unfastened and permitted to hang down in elegant festoons over the sides of the boxes. Frost scarcely hurts even the finest of them, and during the duldest winter months they are almost as bright as in summer. All strong-growing sorts, for covering walls, are kept in pots in the open ground, and one of the finest of all Ivies for that purpose is *Hedera Rægneriana* or the Irish Ivy (*H. hibernica*.)

CULTURE OF THE RASPBERRY.

THE Raspberry delights in a deep, rich, moist soil; still it may be profitably grown in any good ordinary land, if deeply cultivated and well manured. Under good cultivation, the Raspberry is capable of yielding a better result than is generally attained. It is too often the practice to allow it to remain too long on one plot of ground; thus not only causing a deterioration in both the quantity and quality of the fruit, but also curtailing the space at command for the necessary rotation of other crops. I have never found it advisable to allow Raspberries to occupy the same ground longer than five or six years, and the new plantation should always be made one year before the old one is destroyed, in order to avoid any falling off in the supply. Raspberries are planted at various distances apart, but the most profitable plan to adopt, especially in inferior soils, is to plant in rows from 6 to 8 feet apart (I prefer the latter distance), and 1 foot apart in the rows; this gives both roots and branches more room for development, and the soil is not so soon exhausted as when the canes are bundled together in the old-fashioned way. The spaces between the rows can be cropped with low-growing vegetables—such as Turnips, Spinach, Cauliflowers, Lettuce, &c.—and in hot weather the Raspberry-canefurnish a grateful shade, beneficial to such crops, and in a measure prevent their bolting prematurely. Whenever it is desirable to make a new plantation, let the ground be trenched at least

two feet deep, and at the same time well manured, burying the manure at least a foot deep, as the surface can easily be enriched by the necessary annual top-dressings. Raspberries may be planted any time up to February, but autumn planting is best. In planting, first mark out the rows at the required distance from each other with the line and spade; then begin at one end of the first row by opening a hole for the first plant, laying the soil taken out ready to finish off the second row coming back. Any handy spademan will work backwards along the mark previously made, expeditiously planting the canes at equal distances in a straight line as he proceeds. I like this plan better than opening a trench with a straight face to plant against, as the roots can be placed in a more natural position; and, as the soil has only to be moved once, the work is more expeditiously performed. The roots should not be exposed to the drying influence of the atmosphere longer than is absolutely necessary, and care should be taken that the buds or eyes at the base of the canes are not injured, as upon their free and vigorous growth depends the future crop. After all the rows are planted, cut down the canes to within 6 inches of the ground, and lay a mulch of half-decayed manure, about 9 inches wide, on each side of the rows. There will be no fruit the first season, therefore no stakes nor any kind of training will be required; and, as I have before stated, the ground may be cropped with low-growing vegetables—always watching, however, that the growth of the young canes is not impeded in any way by any overhanging or rampant-growing crop. All weak canes should be thinned, or cut away, as the growth progresses during summer, and the following winter they should receive their final thinning to about 8 or 9 inches apart. At this time some provision must be made for supporting and training, to prevent the fruit from receiving injury by winds. The following is the plan we adopt:—Stout stakes are procured, and are pointed round at the lower ends (not angular), and the ends afterwards charred in the fire to preserve them. They are then driven in at 10 feet intervals in a straight line along each row, and the tops sawed off at 4 feet from the ground; this will be high enough for most kinds of Raspberries; but if the canes are very strong they may be left 6 inches higher, as Raspberries usually bear best at the ends if the wood is well matured. Drive a nail in the top of each stake, and stretch a galvanised wire along the top, giving it a twist round each nail to tighten it, and secure it firmly at each end. Another wire may also be run in the same manner about 2 feet from the ground. When the canes are neatly tied to the wire with small twigs of the Golden Willow, the whole quarter will have a neat and dressy appearance. Raspberries should always have a good top-dressing of old hot-bed manure every autumn, but not to be dug in deeply close up to the roots; and in summer—in dry, hot weather—they should be mulched with Grass, litter, or something similar, as a precaution against the effects of drought. With proper means and space there is no difficulty in having a constant supply of Raspberries in succession from July till October, or, if the autumn is mild, till November; and this, too, may be accomplished without growing many kinds—one or two good old kinds, such as the red Antwerp and Barnet, Cox's Honey, or some other good yellow, and Rivers's large-fruited monthly for autumn bearing. If early in May, the young bearing shoots of a portion of the Antwerp or Barnet are cut off; a second growth will be produced that will bear a good late crop, and succeed those of the same kinds that have not been cut back, and produce fruit of better quality than the usual autumn-bearing kinds; and I need not say how desirable it is to have a supply of fresh Raspberries through the summer and autumn months. The autumn-bearing sorts should be cut close down every winter, and all the weakly growths well thinned out during spring and early summer; they will then bear well in September and October, and I have, in some seasons in Norfolk, gathered fruit partly through November. Raspberries are usually propagated by suckers or offsets; they may also be increased by pegging down some of the strong shoots in March, and, treating them as layers, all the buds will push up canes and strike root. Raspberries are easily forced; and, when early fruit is desired, four or five strong canes each may be planted into as many 11-inch pots as there is room for. The potting should be done early in autumn; or, better

still, grow them in pots for one season, plunged in the open air. Forcing should not begin too early—not before the first week in February.

E. HOBDAV.

Apples for Northumberland.—The following list of first-class kitchen and dessert Apples may be of use to your correspondent "J. H.," Northumberland (see p. 61). They are what I have selected from an orchard planted here about ten years ago, the situation being very exposed, the soil strong loam, with a red clay sub-soil, but well drained. Kitchen Apples—Lord Suffield, September and October, great and sure bearer; Cox's Pomona, October to December, fine colour and good bearer; Cellini, October and November, large and handsome, good bearer; New Hawthornden, October to January, great bearer; Duchess of Oldenburgh (Russian), sets well in frosty springs, and not so liable to the American blight as others; Blenheim Orange, good for kitchen or dessert, great bearer; Tower of Glammis, valuable as a sauce Apple, great bearer, November to February; Northern Greening, November to April, excellent keeper; Norfolk Beaufin, December to April, good bearer; Rymer, December to April, good sauce Apple; Dumelow's Seedling, or Normanton Wonder, the best sauce Apple, keeps till April; Sturmer Pippin, keeps till June or July, great bearer. Dessert Apples—Irish Peach, the best, very early Apple, July to August; Kerry Pippin, August to September, good bearer; Red Astrachan, July to August, good bearer; Margil, fine flavour, like Ribston Pippin, great bearer, September to October; Cox's Orange Pippin, fine flavour, October to November; King of the Pippins, great bearer, October to November; Golden Reinette, great bearer, October to November; Sykehouse Russet, good bearer, January to March; Lamb Abbey Pearmain, good keeper and bearer, January to March; Keddleston Pippin, fine flavour, January to March; Lord Burleigh, fine flavour, April to June; Sturmer Pippin, for keeping the latest, April to July.—WILLIAM TILLERY.

Wintering Vines in China.—In the north of China, on the approach of winter, the Vines are taken down from the trellis-work to which during summer and autumn they had been attached; long pits of from 2 to 3 feet in depth being dug, the stems and branches are first trimmed, then laid longitudinally in them, and the whole covered up with soil. Thus they remain protected from the severe cold of winter until the following spring, when they are once again brought to light, are ranged upon the framework newly erected for them, and otherwise prepared for bearing their luscious fruit, several varieties of which are cultivated for the table, but as yet none for the purpose of yielding wine. During the latter part of 1860 and the greater part of 1861, it was my daily habit to take my walks and rides in the vicinity of Tientsin, in order to observe the botany and natural history of the locality; in the latter half of March I have seen the process of disinterring the Vines, and arranging them for bearing, as the temperature of spring increased; and it did so very rapidly; tendrils, that but a few days before appeared like so many dry and sapless twigs, sent forth their buds; a few days more the buds had developed into leaves, and, ere a month was past, the rich green foliage was such as to yield refreshing shade from the heat, which, by the latter end of spring, had become unpleasant during the three hours after mid-day.—G. A. GORDON.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Pear-trees in Bloom.—Owing to the mildness of the season, I have Pear-trees nearly in full bloom, and, in order to try an experiment, I have potted and placed them in the orchard-house with my Peaches and Nectarines. Common China Roses are also thickly in blossom in this neighbourhood.—Yeovil.

Blackberries.—Can any of your readers tell me how it is that the Blackberry is not among our cultivated fruits? If it were improveable in anything like the same proportion as the wild Raspberry or Gooseberry, to say nothing of the Strawberry, it would well repay the care bestowed on it, and the idea is so obvious that one would suppose there must be some insuperable difficulty in the way of carrying it out. Where can I get any information on the subject?—B. W. S.

New Early Plum.—The current number of the *Revue Horticole* contains a coloured plate and a description of a new early Plum, the Normande précoce, which ripens from the middle to the end of July. The tree is said to be of very vigorous growth, with long and thick branches. The fruit, which is usually produced in twos and threes, is of a light purple colour, large size, and first-rate quality. This variety is a seedling from Reinette précoce, raised about ten years since, and fruiting for the first time in 1871.

Apples Kept Two Years.—At an entertainment given to the members of the Massachusetts Board of Agriculture, at the house of Captain E. T. Miles, during the late meeting at Fitchburg, among other rare and choice fruits were several baskets of Roxbury Russets, of the crop of 1872, in a remarkable state of preservation, being sound and quite plump, and retaining a fair proportion of their original flavour. Captain Miles's foreman informed the editor of *The N. E. Farmer* that he considered it no wonderful feat to keep Apples in good condition two years. He keeps them in barrels in a cold cellar, has the barrels as nearly air-tight as possible, heads them up after they are entirely past all sweating stages, and does not look them over till wanted for use.

GARDEN DESTROYERS.

THRIPS.

THESE may be classed with the worst insects with which we have to contend, especially in the indoor department. They do not increase so fast as the aphides, yet in some cases, as when they attack Vines, they are more difficult to destroy. The black thrips are most destructive to Azaleas, Vines, and Ferns under glass, and to such things as Dahlias, Phloxes, and Verbenas out of doors. In some localities they attack late Peas in such numbers as to almost destroy the crops. The means required for their destruction vary with the different plants, and the conditions and situations in which the plants exist. Azaleas are more liable to their ravages than any other plants, and, unless means are taken to destroy them as soon as they make their appearance, they do irreparable mischief by destroying the vitality of the leaves, causing them to fall off prematurely, and correspondingly weakening the root power. They require a higher temperature than aphides to bring them into life; but, in the stove, the eggs hatch in about three weeks. Except in houses that are kept warm through the winter, the female deposits and seals over her last eggs late in the autumn, and dies, unable to withstand the cold. The small black varnish-like spots, most generally found on the backs of the leaves (and which are often mistaken for the excrement of the insects), are the sealed-up eggs, ready to come into life as soon as the plants are subjected to artificial heat, or naturally by the increase of solar heat in the spring. If this last batch of eggs is thoroughly destroyed in the autumn, the plants stand a reasonable chance of escaping their attacks the following summer. Fumigation, no matter how strong the application, is of no use for the destruction of the eggs; consequently, it becomes necessary to employ other means. The best method for small plants is dipping them in moderately strong tobacco-water, to which has been added 2 oz. to the gallon of Gishurst, which softens the tobacco-water, and counteracts the injurious effects that the oil which it sometimes contains has upon the leaves of plants. For large plants that cannot be dipped, it is necessary to lay them down on their sides and syringe them all over, turning the plants during the operation, so as to thoroughly wet every leaf on both its upper and under surface. Not a single leaf should be missed, or the chances are that the dressing will not be effectual. Allow the mixture to dry on, and it will destroy the vitality of the eggs effectually. In the operation of washing it is necessary to use a trough, over which to lay the plants whilst being syringed, otherwise serious waste will occur. Every garden where plants are grown ought to be provided with a trough of this description; it should be made of strong galvanised iron, 6 feet square and 10 inches deep, strengthened in the rim and across the bottom with stout iron wire. After syringing, allow the plants to lie on their sides until the liquid is quite dry upon them, as it is not desirable that it should run down in any considerable quantity amongst the roots. Plants that have been much affected with the insect should be washed in this manner twice, at an interval of a fortnight, in the autumn; and, if it is thoroughly well done, very few will be attacked with the insects the following summer, unless some affected plant is introduced amongst them. During the growing season, the plants should be frequently examined, and, as soon as any of the thrips are discovered, they should be at once washed with the mixture, not allowing them time to spread. Thrips may be destroyed by tobacco-smoke, but I do not approve of fumigating Azaleas, as I never saw a sufficiently strong application of the smoke to kill the insects without injuring the leaves, causing them to fall off prematurely; consequently it is much safer to destroy them by the application of tobacco-water. In the stove, Ixoras, Dipladenias, Francisceas, Crotons, with numbers of other plants, are subject to their attacks. I find the best remedy is to wash the affected plants with "Fowler's Insecticide," used 4oz. to the gallon, dipping and syringing the plants in a similar way to that described for the Azaleas. Where these insects get amongst Vines, they do serious mischief. After the crop is cut, the living insects can be killed by repeated smokings; not so their eggs, which are deposited thickly on the young wood ready to come to life when there is sufficient heat to hatch them. The usual winter

dressing of sulphur, clay, and soft-soap, thoroughly applied, is sufficient to destroy them; but if they attack the Vines early in the season, or before the crop is cut, fumigation will not answer, for the Grapes will taste of the smoke to an extent that will spoil them. Sulphur mixed with clay and a little fresh lime, applied to the pipes in the same way as for red spider, will kill the mature insects, and the application must be repeated three times at intervals of eighteen or twenty days, so as to kill the young brood as they are hatched, before they have had time to breed. When they make their appearance upon Cucumbers or Melons grown in houses or moderately large pits, the best plan is to fumigate repeatedly, but not too severely, or the plants will be so far injured as to make them useless; and, even in houses of this description, if they get established upon the plants in winter or early spring, the plants are rarely able to withstand sufficient smoke to kill the insects. Careful syringing with tobacco-water, using a very fine Rose, is the best and safest remedy; but, for these plants, there must be no Gishurst added to the tobacco-water, or it will kill all the points of the young shoots. When they make their appearance on these plants, in small pits or garden frames, they may be destroyed if taken in time by sponging the under-side of the leaves with tobacco-water. Dahlias, Phloxes, &c., are very subject to them in some localities; nothing here can be done but frequent use of syringe or garden-engine, as they cannot bear repeated immersion in water. In the greenhouse, Fuchsias, Cytisus, Statice, Hydrangeas, Camellias, Vallotas, Cyclamens, and Cinerarias, are a few of the plants which they attack; here fumigation, repeated until they are destroyed, is the best remedy. In some localities, generally in dry situations, they are very destructive out-of-doors. About July, in a dry season, they generally make their appearance upon Peas, scores of the insects getting into every flower as soon as it is open, and causing a malformation of the young pods, so that they frequently do not contain more than one or two Peas. A liberal use of the garden-engine two or three times a week will keep them in check, so as to prevent their doing serious harm.

The small yellow thrips is a more difficult insect to deal with than the black one. The plants they attack are somewhat different, and not so numerous. Fumigation of this insect is almost useless, from its habit of establishing itself down in the bottom of the young leaves as they unfold. Here there appears to be sufficient stagnant air to supply their breathing until the fumes escape from the house without injuring them in the least. In the stove, Allamandas, Crotons, Francisceas, and winter Cucumbers, suffer much from their attacks; for the latter, careful and repeated use of clean tepid water, applied with a fine-rose syringe all over the plants, but more especially the under surface of the leaves, is the best remedy. Allamandas, Crotons, or any plants of similar description should be regularly well syringed with clean water, and an occasional washing with a weak solution of Fowler's Insecticide at 2 oz. or 3 oz. to the gallon. But it is to Orchids that this insect does the most mischief. Amongst East Indian species, such as Phalænopsis, Saccolabiums, Aërides, and Vandas (getting down into the heart of the plants, disfiguring the young unfolding leaves, and, if left unchecked, entirely destroying them), Cattleyas, Dendrobiums, Oncidiums, Odontoglossums—in fact, on almost any species of Orchid—they appear to be at home. Fumigation here would be of little avail, even if all Orchids would bear it. All insecticides with which I am acquainted do harm to the plants. I have seen soft fleshy-leaved plants like Phalænopsis killed outright by the use of Gishurst and similar compounds; consequently, they should never be used. I have seen tobacco or ordinary snuff blown into the crown of the plants; this partially destroys the thrips, but it is objectionable; if water gets along with it into the hearts of the plants it frequently rots them. By the continued use of a very small bit of sponge tied on the point of a stick, so that it can be got down into the young unfolding leaves, or a small camel's-hair brush just damped with clean water, they may be kept under; but it is a slow process, and, unless where there are few plants, it is scarcely possible by this means to completely eradicate them. Continued application of clean tepid water, syringed over-head every other day during the growing season will soon completely destroy them. Care must be taken that

the water gets right into the crown of the plants, otherwise it will not be effectual. Some growers object to this syringing overhead, alleging that it frequently rots the young growth. Such will be the case where Orchids are grown on the coddling system, with too much heat, too much atmospheric moisture, too much shade, too far from the glass, insufficient air, not enough rest in the winter; and these are the conditions under which the greatest number of Orchids in the country exist, entailing four-fifths of that fatal disease, the spot, and rendering these naturally strong-constituted plants unable to withstand that necessary, as well as most natural, way of applying water overhead. Winter Cucumbers are frequently attacked by these insects; here they are more difficult to deal with, as at this season the plants do not well bear the amount of syringing overhead required to keep the insects down. A syringe with a very fine rose should be used, so as to wet the whole surface of the plants with as small a quantity of water as possible. They are sometimes troublesome on Peaches and Nectarines under glass, as well as on open walls; this generally happens where an insufficiency of water has been used overhead. Here they do the most mischief in the last stages of ripening, congregating by hundreds upon the ripe fruit, and much damaging its appearance. Nothing can be done here except to use the syringe or garden-engine, and too much water overhead at this time injures the flavour of the fruit. The best practice is prevention by a liberal use of the syringe or engine all through the early stages of growth. This insect is a continual source of annoyance through the summer to the Auricula-grower, seriously injuring the young leaves as they unfold, and, if left undisturbed, will quickly destroy the plants. I once had charge of a collection of these plants, and soon found that the time required to catch the insects singly by the old method of employing a flat-pointed stick, wetting the point so as to cause them to adhere to it, and then crushing them by hand, was more than could be spared; so I tried fumigation, and found that the plants would stand it, applied sufficiently strong to kill the insects, matting the frames well up to retain the smoke.

T. BAINES.

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

Destroying Snails.—Snails may be enticed to harbour in and feed on bran, if placed in handfuls where they are numerous. Every morning the places should be examined and the snails destroyed. Quick-lime, if dusted on the rows of early Peas, and other early vegetables, in spring, when the dew is on them, is a certain cure for snails, if persevered in.—W.

Wire-worms.—These are found in the greatest quantities in fresh new loam, just brought from the fields, and such soil, when used for valuable plants, should be carefully examined, and the wire-worms crushed; their brownish-red bodies are easily seen. Slices of Potatoes or Lettuce stems will likewise entice them where they are numerous. The slices should be placed under ground, and then frequently examined. This year I saved a bed of seedling Gladioluses that were planted in some new loam, which I found afterwards swarmed with wire-worms, by placing slices of Potatoes and Lettuce stalks in the ground, after I found that some of the plants were flagging. By this means I saved the rest from being attacked so much afterwards.—W. TILLERY.

THE FLOWER GARDEN.

CASTOR-OIL PLANTS.

THESE very ornamental foliage-plants are said by M. Mueller (who has studied the genus very attentively) to belong to a single species, *Ricinus communis*, of which he considers all the kinds in cultivation to be mere varieties. In his monograph on the Euphorbiaceæ, M. Mueller states that, up to the year 1866, he had established sixteen leading varieties and twenty sub-varieties of *Ricinus*. Like the Cannas, these plants manifest a remarkable tendency to natural hybridisation, and M. André states that, in raising them from seed, so many varieties are produced that in two generations it is difficult to find a seedling resembling the original type.

The following are descriptions of the type and twenty of the principal varieties grown by M. André:—

RICINUS COMMUNIS.—A native of the East Indies, but growing freely in the open air in this country in the summer months. Planted out in some of the London parks, it attains a height of nearly 12 feet, and produces leaves nearly 3 feet across. The stem is jointed, of a purplish-red colour, covered with a glaucous bloom. The leaves are palmate, deeply divided into five, seven, or nine oval-lance-shaped segments, which are unequally toothed at the margin. The flowers are borne in spikes, but are insignificant in appearance, as the corolla is wanting. The fruit is a tolerably large three-celled capsule, covered on the outside with prickles, like the fruit of the Horse Chestnut. Each cell contains one seed about the size and shape of a French Bean. From these seeds the castor-oil of commerce is extracted; the seeds being first boiled, and afterwards submitted to pressure in a hydraulic press. This plant is largely grown in Algeria, where it often attains a height of from 22 to 26 feet.

Varieties.

1. *R. PURPUREUS MONSTROSUS*.—Grows about 10½ feet high. Stem, simple, as thick as a man's arm, of a

deep reddish-brown colour suffused with rose, as are also the long and stout leaf-stalks; leaves, large, deeply lobed, of a deep green colour, with bright red nerves or veins; flower-spikes, very large, pyramidal in shape; flower-stalks, red; capsules, large, deep green, with reddish prickles. A magnificent plant.

2. *R. AFRICANUS ALBIDUS*.—Grows about 8 feet high; moderately vigorous. Entire plant of a pale yellowish glaucous green colour. Stem and leaf-stalks of a hoary yellowish colour, tinged with very deep green; leaves, small, of a lively green colour, with yellow nerves or veins; flower-spikes, small, hoary or frosted green; capsules of medium size, with pale yellow prickles.

3. *R. BORBONIENSIS RUBRICAULIS*.—A very strong-growing variety, about 8 feet high. Stem, violet-green at the base, hoary purplish-violet at the top; leaves, large, flat, not much divided, deep green, centre starred with rose-colour; nerves or

Ricinus sanguineus.

veins, rose-colour; leaf-stalks, long and slender; flower-spikes, of medium size, on rose-coloured stalks, marbled with green. Capsules, large, of a deep green colour, with a bluish iridescence.

4. *R. ELEGANTISSIMUS*.—Grows about $5\frac{1}{2}$ feet high. Stem, slender, with long internodes or joints, of a reddish-purple colour; leaf-stalks of the same colour, long, slender, erect; leaves, deeply cut, of a lively green colour, with bright rosy veins or nerves. Capsules of a uniform ashy-green tinge.

5. *R. BORBONIENSIS*.—A variety with very few branches, growing nearly 10 feet high; stem, very stout; leaf-stalks, long, stout, much swollen at the base, streaked (as is also the stem) with fine red and green longitudinal lines; both covered thickly with a bluish rose-coloured bloom; leaves, very large, of elegant shape, divided to the middle, standing far apart, and of a fine green colour; flower-spikes, short; capsules, large, of a bluish-green colour, with stout prickles. A very handsome variety.

6. *R. COMPACTUS*.—A very branching plant, about 8 feet high; stem and leaf-stalks of a deep reddish-purple colour, like those of No. 1; leaf-stalks, long and slender; leaves, very deeply cut, and margined with very large unequal teeth; veins or nerves of a lively rose-colour; flower-spikes, long, dense, and erect; capsules, of medium size, blackish green, with stout prickles.

7. *R. AFRICANUS HYBRIDUS*.—A vigorous-growing plant, nearly 10 feet high; stem, thick, with long joints or internodes, of a deep violet-purple colour; leaves, broad, of a deep brilliant green colour, with bluish reflections, and bright red veins or nerves; capsules, of medium size, deep green, on long stalks, and with long yellow-pointed prickles, standing far apart.

8. *R. SANGUINEUS GLAUCUS*.—A short-branched plant, about 6 feet high; stem, of a light violet-purple colour; leaves, firm, with short ill-defined lobes, of a dull deep green, tinged with reddish; veins or nerves, forming a central red star; leaf-stalks, slender, streaked with purple and green, and covered with an ash-coloured bloom (as is also the stem); flower-spikes, short; capsules, large, white and red, with strong twisted prickles of a delicate rose-colour.

9. *R. SANGUINEUS MINOR*.—A plant of small or medium-sized dimensions, about 6 feet high; stem, of a very deep reddish-purple colour; leaf-stalks, of a lighter shade; leaves, deeply lobed, and edged with broad teeth, of a handsome deep green, shaded with violet when young, nerves or veins, very prominent, and of a deep crimson colour; flower-spikes, short; capsules, purplish-green; points of the prickles, deep red.

10. *R. NANUS MICROSPERMUS*.—A branching plant, about $6\frac{1}{2}$ feet high; stem, stout, of a deep purple streaked with rose-colour; leaf-stalks, long and stout; leaves, large and handsome, with very broad large-toothed lobes, orbicular in outline, and resembling those of *R. viridis*; nerves or veins, prominent, rose-coloured, well-marked, and radiating regularly; flower-spikes, large; capsules, numerous, closely set, of a very deep green colour, relieved with bluish and purple tints; prickles, short, green.

11. *R. AFRICANUS*.—A plant of weak growth, and of branching and bushy habit, about $6\frac{1}{2}$ feet high, with a prevailing tint of glaucous green or ashy-yellow, owing to the presence of an abundant light-coloured bloom on the branches and stem; flower-stalks, long and slender; leaves, small, not deeply cut, of an ashy-green colour, with pale yellow nerves or veins; flower-spikes, short, numerous, unequal in size; capsules, of medium size, drooping, of a uniform glaucous-green colour. (I suspect this to be no other than *R. africanus viridis*, and not the true *africanus*, which is the same as the *R. major*, or Giant Ricinus, of the gardens.)

12. *R. (SPECIES FROM THE PHILIPPINE ISLANDS?)*.—A plant of an entirely yellowish-green aspect, something like the preceding variety, but less glaucous, and growing about $6\frac{1}{2}$ feet high; leaf-stalks, long, slender, and of a marbled-green colour; leaves, with broad undulated finely-toothed lobes, and yellow nerves or veins; flower-spikes, stout, short, and compact; capsules, large, of a uniform ashy or glaucous green, on short stalks; prickles, short and green.

13. *R. SANGUINOLENTUS*.—This is, undoubtedly, the handsomest of the whole collection, as regards colour; grows $6\frac{1}{2}$ feet, or more, high; stem, simple, of a very deep reddish-purple,

with a shining surface; leaf-stalks, long and stout, of the same colour, mixed with green, somewhat erect, and close together; leaves, very large, neatly cut (the lobes not extending to the middle, and of a lance-shaped acute form), of a general reddish-purple and violet colour, with metallic reflections, like those on the neck-feathers of some pigeons; nerves or veins, very prominent, of a bright blood-red colour, which remains when the leaves become old and change their colour to a deep green, with purple reflections; flower-spikes, large, pyramidal, dense; capsules, large, blood-red, with long deep red prickles. This variety ripens its fruit very slowly.

14. *R. GUIANENSIS*.—A branching variety, of moderately vigorous growth, about $6\frac{1}{2}$ feet high; stem, of a mingled reddish and light violet-green colour, covered with an abundant whitish ash-coloured bloom; leaf-stalks, slightly reflexed; leaves, large, well-formed, deeply and elegantly cut into pointed lobes, of a deep glistening green colour, with red veins or nerves; flower-spikes, thinly set with flowers; capsules, large, of a pale ashy-green colour; prickles, rose-coloured.

15. *R. MACROPHYLLUS ATROPURPUREUS*.—This variety resembles the preceding, but is more vigorous in growth, and has a more erect habit; grows about $5\frac{1}{2}$ feet high; leaves, broad, handsome, deep green, with a large central star of red nerves or veins; capsules, like those of the preceding kind.

16. *R. MACROCARPUS*.—About $5\frac{1}{2}$ feet high; stem, green, streaked and marbled with rose-colour, slightly glaucous; flower-stalks, slender, deflected, then recurved and standing erect; leaves, very large, orbicular in outline, with very broad short lobes, of a uniform brilliant green colour, with stout bright yellow nerves or veins; flower-spikes, depressed; capsules, bluish-green, on short stalks; prickles, short and thick, of a pale green colour.

17. *R. INSIGNIS SPECTABILIS*.—This plant hardly bears out the promise of its high-sounding title. It is very like the preceding variety, but smaller and more glaucous; the leaves are deeply toothed; the nerves are of a paler hue; the capsules have a bluer tinge; and the prickles are curved and longer.

18. *R. SANGUINEUS TRICOLOR*.—The specific name of this variety is also not well applied. It grows about $6\frac{1}{2}$ feet high; stem, simple, stout, of a deep blood-red colour, and handsome appearance; leaf-stalks, long, growing at right angles to the stem; leaves, neatly cut into lance-shaped pointed lobes; nerves or veins, broad and equal, of a delicate rose-colour; flower-spikes, pyramidal, dense; capsules, of a blood-red colour.

19. *R. PURPUREUS MAJOR*.—Grows about $6\frac{1}{2}$ feet high; stem and leaf-stalks, deep reddish-purple. In habit and foliage this variety resembles the preceding one, but the leaves are broader, and the nerves or veins are of a lively red colour; flower-spikes, of medium size; capsules, large, green, with reddish prickles.

20. *R. PURPUREUS*.—A vigorous-growing variety, about $6\frac{1}{2}$ feet high; stem, stout, of a violet-red colour, covered with a hoary bloom; leaf-stalks, slender, marbled with rose-colour, white, and green; leaves, neatly cut into lance-shaped pointed lobes, of a brilliant green colour; nerves or veins, rose-coloured, not prominent; flower-spikes, short, bluish-green; prickles, short, with rose-coloured points.

Of the foregoing varieties, Nos. 1, 3, 5, 10, and 13 should be selected by those who prefer cultivating a few fine sorts to the possession of a large indiscriminate collection.

RARE LILIES.

For years past, Japan has been pouring in upon us her horticultural treasures in many forms, but notably so in the abundance of her rare and beautiful Lilies, giving to this family a first-class place amongst decorative plants, and bidding fair to revive that enthusiastic spirit amongst amateurs which our modern style of gardening has much tended to extinguish. North America, especially California, promises to run Japan close in the race of Lily introductions, and to show that her mineral wealth is but one of her excellencies; for, while she has been fertile in the precious metals, she has been developing a superb flora, and her recently-found Lilies are amongst the most magnificent in cultivation. At the head of the list conspicuously stands *L. Humboldti*, the grandest of all Lilies, and one that, from its constitution, bids fair to make

permanent residence amongst us. India, in its temperate regions, has a Lily flora second to none in beauty, stateliness, and fragrance. Our knowledge of the species is, however, limited. From time to time one or other has been introduced, but *Giganteum* alone remains; the others have been lost, it is supposed, from over-coddling, treating them as stove plants, whereas they come from regions where the frost in winter is severe, though the temperature in summer is high; but this may be said of the native habitats of almost all our Lilies which lay pretensions to the title of beautiful; for example, the Caucasus, North America, Japan, and Southern Europe; these are the places from which our Lilies mostly come, and, while I cannot precisely imitate soil, situation, and climate, I can do much to adapt them; and it is with this object I have prepared this article, some important notes having come to me from an Indian correspondent, accompanied by the two rare Lilies, *Wallichianum* and *polyphyllum*.

"*L. WALLICHIANUM*," says Baker in his "Synopsis," "stem reaching 4 to 6 feet high, half an inch thick at the base; leaves, thirty to forty, always narrow, linear, ascending, the lower reaching 8 to 9 inches long, 3 to 6 lines broad below the middle, narrowed very gradually to an acuminate point; flowers, two to three, ascending or horizontal; perianth, 7 to 9 inches long; the neck of the funnel, 3 to 3½ inches long." This might fairly be placed as a species of full rank; for in the height of its stem, size and fragrance of the flowers: it is the prince of the *Longiflorum* series.

"*L. POLYPHYLLUM*.—Stem, 2 to 3 feet high, moderately stout, glabrous, terete; leaves, all scattered, thirty to forty to a stem at the flowering time, much ascending, linear, lanceolate, the lower ones 4 to 5 inches long, 6 to 8 lines broad above the middle, narrowed gradually to the base and an acute point, similar to those of the *Martagon*, and much thinner than those of *Carniolicum* in texture; the veins, fine and anastomosing, both sides glabrous, the edge not at all scabrous or ciliated, the upper ones ceasing several inches below the inflorescence; flowers, four to six in wild specimens, on a lax raceme; perianth, 18 to 21 lines deep, reflexed from below the middle when expanded, drooping, as in the other *Martagons*. It has never been in cultivation; colour of the flowers unknown." My Indian correspondent from Mussoorie writes of *L. Wallichianum* thus:—"Flowers in August, but more usually in September. It is a hardy plant, and here defies both heat and cold. I find it growing, at an elevation of 5,500 feet, on the open grassy hills, with a slope often of 45°, not under forest shelter, but in the open tracks; the soil full of bits of limestone pebbles, and the matrix composed of lime, clay, and vegetable mould. From the great slope of the hill, it is thoroughly free from surplus water, the temperature of the summer sun being from 120° to 130°. From June to the end of September it grows in a perfect deluge, and often enshrouded in mist for days together, that being our rainy season. From September to December it gradually dies down in a fine warm temperature by day, with hoar-frost at night in November. Little rain falls during these months. Sometimes there is but little snow in winter, say 3 to 4 inches, with hard frost; at other times, the snow lies over them 2 feet in depth, but this is unusual. The bulbs lie at a depth of 6 to 9 inches, and are uninjured. The plant seldom or never produces seed, but is propagated by suckers or by bulblets from some part of a long root, so that the flowering plants are surrounded by numerous young ones of various ages." Another correspondent writes:—"Wallichianum is certainly a magnificent Lily. I have seen it in the Himalayas 8 feet high."

Of *L. polyphyllum*, my Indian correspondent says:—"It is one of the Turk's-cap group; grows in good tolerably moist vegetable mould, on a slope in thick shrubbery; and flowers here in June, at an elevation of 6,500 feet." And he adds:—"I have sent you an *Amaryllis*, now for the first time procured. I have not seen the flower; but the lad who found it says it throws up a smooth stalk, bearing Blue-bell-shaped flowers, disposed on alternate sides like *L. giganteum* and *L. roseum*. It was found on the margin of a stream, at about 5,000 feet of elevation, at the bottom of a deep wide valley. This is the first *Amaryllis* I have yet found on these hills."

PETER BARR.

BEDDING CALCEOLARIAS.

WE cannot as yet dispense with the *Calceolaria* as a bedding plant so long as the present system of massing in colours continues, and especially is this true of the yellow bedding varieties; for, notwithstanding that several yellow-flowering plants have been suggested as substitutes, such as the Pansy, *Tagetes signata pumila*, dwarf *Nasturtiums*, dwarf Marigolds, &c., yet there is not much probability of their becoming so generally employed as the *Calceolaria*. The bedding *Calceolarias* have fallen into much disrepute with flower gardeners of late, owing to their fatal tendency to show the possession of disease. Whether this is an epidemic like the Potato disease, or whether it is owing to mismanagement, has not been clearly demonstrated. Certain it is that in cases where particular attention has been turned to the treatment of bedding *Calceolarias* during the winter, the ravages of the so-called disease have been much lessened; in some instances it has been stamped out altogether. Roughly stated, the common treatment is as follows:—Cuttings are taken off at the end of July or during August and put into store pots, in which they root. They are frequently neglected at this stage, and become dry, scrubby, and infested with greenfly. In the spring, the cuttings are potted off singly into small 60-pots and pushed on into growth, and then allowed to become pot-bound, and to suffer from want of water. Then in May or June, they are turned out of the pots with their hard balls of roots into the open ground in a somewhat unhealthy state through neglect, and the result is the certain loss of many of the plants. A mysterious disease, inexplicable in cause and action, is credited with the destruction, and it is concluded the bedding *Calceolaria* cannot be grown. The plants are kept in a hot dry atmosphere for a great part of the winter. They suffer from confinement at the roots at the time when they should have the fullest liberty to develop themselves; the plants become weakened and scrubby when they should be strong and robust; and what wonder is it that they succumb to hostile influences? A much more sensible and safer course is to take the cuttings at the usual season of the year, and dip them for a few minutes in a solution made of 3 oz. of Gishurst's compound, dissolved in a gallon of soft water, and allowed to stand for twenty-four hours before being used; then the cuttings should be dried in the sun, and pricked out into shallow boxes, or in a bed in a cold frame. The siftings of the refuse of the potting truck can be turned to good account in this way. There is nothing like a bed in a cold frame, and here the cuttings speedily root. After being kept close for a few days, air should be given on all suitable occasions; but, if hard frost sets in, some protecting material should be thrown over the frame. In February or early in March, cut a trench across an unused part of the kitchen garden 3 feet in width by 18 inches in depth, and fill it with about 6 inches of any light soil, such as the refuse of the potting truck; and, about the middle of March, plant out the rooted cuttings of *Calceolaria* in lines about 6 inches apart each way. When the trench is filled, bend over it some stout sticks to form a rough framework on which mats can be laid to give shelter when necessary. On all occasions air should be given, and water when needed. Plants treated in this way will be certain to do well when transferred to the flower-beds; and very seldom indeed is it that any loss takes place. The great thing is not to put out plants that have had their roots confined in pots during the winter till they have become little better than a dried half-decayed ball. Plants lifted from the trench, as directed above, at once lay hold of the soil; for, the roots, having been perfectly free and unconfined, are in the highest stage of development. Perhaps there is no flower garden where more *Calceolarias* are bedded out and flourish better when planted than at Hatfield House, the Hertfordshire seat of the Marquis of Salisbury. The plants are treated in the manner just indicated. The growth is luxuriant, the bloom most profuse; and yet the Hatfield Terrace flower-gardens are as much exposed to the action of the sun as gardens can well be. Plant out, if possible, when a shower is imminent; it settles the soil nicely about the roots, and root-growth is made at once. The fine old *aurea floribunda* still holds its own as a good dwarf yellow bedding *Calceolaria*, compact in habit, and free and continuous in bloom. Golden Gem is a newer variety, and is considered to be the best of all the yellow *Calceolarias* in use, even more hardy and compact in growth than *aurea floribunda*, of a deeper yellow hue, and less affected by weather. Some beds and lines of this variety formed a leading feature in the effective flower garden at Auckland Castle, the residence of the Bishop of Durham, during the past summer. The old *amplexicaulis* is still much grown for its clear pale straw-yellow colour and general effectiveness. A new dwarf sulphur-yellow bedding variety, named Princess Louise, is highly spoken of by many growers. Another, named *elegans*, has clear golden-yellow flowers, and it does well. Of amber-coloured flowers, Beauty of Herts stands pre-eminent; it has a fine dwarf, robust, free-branching habit, and blooms profusely.

This is largely grown at Hatfield. The old Prince of Orange and Princess Alexandra, having striking orange-buff flowers, also come into the group. Then, of red and crimson flowers we have Bijou, beautiful brilliant crimson; Crimson Dwarf, dense compact habit, very free and profuse of bloom; and Victor Emmanuel, reddish-scarlet, distinctly spotted with crimson, makes a fine bedder also.

R. D.

MR. ATKINS'S PLANT-COLLECTORS' BOXES.

THE favourable allusion made by our correspondent, Mr. Elwes (see p. 53,) to the kind of boxes used by Mr. Atkins, of Painswick, when collecting plants, induced us to write to that gentleman for further information respecting them, and he has kindly furnished us with the following reply:—"My collecting boxes or trays are very simple, but effective. I have for many years used them when far from home, on the Alps and other localities, and, by taking every opportunity of removing the lids to expose the plants to light and air, with an occasional sprinkling with water all over the plants, especially in the evening, I have travelled with them for many weeks, and found my plants at the end of the journey in the best of health, and grown together into one mass, so as to require a knife to separate them. I use shallow boxes or trays; a convenient size I have found to be about 18 to 20 inches long by 13 to 14 inches wide, and 3 inches deep in the clear (inside measure), but, of course, the size and depth must be somewhat guided by the description of plants they are intended for. The above I have found ample for such as Gentians, Soldanellas, Myosotis, Androsaces, Saxifrages, and such like. If too large, they are cumbersome to move about, and more apt to get damaged in transit. Let them be well made of seasoned $\frac{3}{4}$ deal, or they will be apt to warp and give way with the damp from the plants. On the four corners of each tray, or box, nail a block of wood about $\frac{3}{4}$ inch in depth, on which the loose lid will rest, thus allowing that space all round for the entrance of air to the plants. These, as collected, with sods of earth to the roots, should, from time to time, on return from each excursion, be firmly pressed, with their balls of earth, close together into the box, the top of the plants being nearly, or quite, level with the sides of the box or tray. If more than one be required, they should be all made of the same size, so that when placed one on the other, the bottom of the one above would form a top, or lid, for the one underneath, and, by being provided with two or three stout leather straps, they are very readily fixed together, and opened when at one's quarters (or when passing Custom-houses), with very little trouble or disturbance. When small plants are placed in one of these boxes, a slight division, or a rod, run down the middle of the box longitudinally, is of advantage in preventing their shifting, or being displaced by being thrown about in transit. The new additions of plants, when placed in the box, should have a moderate watering to more effectually unite them with those previously placed therein; and then, in an hour or two, by tipping the box on one edge, you may effectually drain them to prevent soddening. Drain-holes in the bottom of the boxes being objectionable for packing with other baggage, the vacant space in each box is best filled with tightly-pressed Sphagnum, or Moss, until required. I never found any difficulty in getting additional trays made in any of the Swiss villages, neatly, and also cheaply.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Winter Flowers.—Crocus Imperati, fawn-colour, striped with black, inside of petals violet, in 1873 and 1874 was in flower January 4 and 11 respectively. Eranthus hyemalis, bright yellow, was in flower January 11. Colchicum autumnale album plenum, casual blooms on January 11. This has been flowering, off and on, over two months in my trial ground.—P. BARR.

Ivy-leaved Geraniums for Rose Stems.—Mr. Dean tells, in the *Florist*, of a graceful way of training these plants up the stems of Rose-bushes. I saw a country flower garden not long since with its inevitable lines of Standard Roses planted in the turf by the sides of the gravel walk, but with a small circular bed at the base of each. In these beds had been planted various-coloured Ivy-leaved Pelargoniums, which were trained up the stems of the Roses, and so furnished them with pillars of leaves and flowers. The association of the Ivy-leaved Pelargonium with the Roses in this fashion quite hid the naked stems from view; and I failed to perceive that the Roses suffered in any way from the companionship of the Pelargoniums, as the heads were of vigorous growth and blooming freely. This combination is worked out every year without inflicting any perceptible injury to the Roses.

The Species of Tulips.—I send a few notes taken from Tchihatcheff's "Asie Mineure," vol. ii., to supplement Dr. Regel's paper on Tulips, published in THE GARDEN last week (see p. 43). Tulipa armena grows at an elevation of 6,000 feet; T. montana found in the Troad, Mysia, at Erzerroum, and on Mount Ararat, at elevations of from 6,000 to 9,000 feet; T. Gesneriana, found in Armenia at from 6,000 to 7,000 feet; T. Julia, also found in Armenia; T. undulatifolia is found in rich pastures near the top of Mount Tahtaln, near Smyrna; T. Sibthorpiana is found at Makri, on the Lycian coast, and at Porto Cavaliere. Two species not noticed by Dr. Regel, are also mentioned, namely, Tulipa pulchella, found by Kotschy, in the Cilician Bulgardagh, at an elevation of 6,000 to 7,000 feet (Ky. Reise in Cilic. Taur. p. 379), and Tulipa Thirkiana, C. Koch. (T. tricolor, C. Koch, in Linn. xix., non Lideb.) [sic, in Tchihatcheff], found near Broussa.—H. J. ELWES.

BOLD VARIETY IN GARDEN SCENERY.

THERE are two ways of obtaining good effects in planting, as in painting, the one being gained by a judicious combination of forms and colours, the other by skilful contrast. Both these plans have their advantages when put into practice, and we not unfrequently see them blended together in happy union, for, it must be remembered that we can contrast forms while we harmonise colours, and *vice versa*; in many cases, indeed, it is best to do so. To plant well, we must have the height, form, and colour-changes of every tree or plant employed in our mind's eye; then some definite result can be worked out from the beginning. Every one interested in planting for landscape effect should pay particular attention to the kind of forms they employ for that purpose, if they would be successful. The columnar Lombardy Poplar, the spreading Oak, the round-topped Ash, the silvery-stemmed drooping Birch, the massive cone-shaped Limes and Chestnuts, or the straight tapering Larch or Firs all assist us, if their forms are judiciously combined with those of trees of a different contour. These may be taken as types, as far as form is concerned, but we must also consider colour, either in harmony or by way of contrast. Here we may have either a soft blending of greens, such as is afforded by Acacias, Limes, Elms, Chestnuts, and sombre Conifers; or contrasts, such as those afforded by silvery Willows, Negundos, purple-leaved Beeches, and golden-foliaged Yews, Maples, or the crimson autumnal foliage of the Oaks and Vines. Our illustration shows the good effects which result from striking contrasts in the way of ornamental planting. The noble round-headed tree in the centre of the annexed illustration is in itself a study, apart from the pleasing types of vegetation with which it is surrounded. The whole picture, in short, teaches us a valuable lesson as regards the grand effects we may produce by boldly varying the garden-landscape, instead of following the nearly universal plan of planting in solid clumps and formal masses. We frequently see planting, in which all the tall and striking subjects are so surrounded by others that their individuality is lost. Mr. Marnock, whom, in matters of taste in landscape gardening, we may now consider our best authority, usually follows a different plan from the common one; instead of placing trees of bold or peculiar habit in the centre of clumps, groups, or masses, he usually plants them on their outer and most prominent edge, or point. Good examples of this may be seen at Montague House, and many other gardens designed by him. In due time, these trees, instead of forming an almost unnoticed unit, in a more or less formal mass, stand forth boldly. But, even if we did not possess these peculiar and striking forms of trees, weeping or otherwise, our commonest round-headed forms would well repay us for the fullest attention we could bestow on their effective grouping. The Horse Chestnut groves at Versailles are as monotonous in their serried level ranks as so much groundsel, but a well-developed tree is one of the finest objects in the vegetable kingdom. So it is of a number of other inhabitants of our gardens. It is, indeed, odd to think that, notwithstanding the number of fine plants and trees in our gardens, we should be so successful in producing the eternal monotony of form that is everywhere seen. As to variety of forms, we can probably grow a greater number at present in the open air than any other country. In tropical and sub-tropical kinds, we can never be so rich in them as warmer countries may become; but, recently, we have developed this type to a large extent; and in deciduous, evergreen, and Coniferous trees and shrubs—all classes strikingly diverse in form—our collections are the fullest ever made. We have a good many Yuccas as hardy as our native shrubs; we have the hardy Palms; we have a host of Cannas with noble foliage, and various other types developed in the sub-tropical garden; we have a goodly number of hardy trees, like the Ailantus and Paulownia, of which, when young, the foliage is large and striking; in fact, we have all that the most fastidious could desire. One type shown well in the illustration is the Umbelliferous—a form rarely seen in garden scenery, except as represented by the coarse and not fragrant Cow-Parsnips. We know of no plants which are likely to be more useful to the garden-artist than the Giant Fennels and their allies, now too much confined to good botanical collections.

F. W. B.

SOILS, FERTILISERS, &c.

PROPER TREATMENT OF YARD MANURE.

FEW subjects are of more importance to the gardener, or have led to the expression of more opposing views from different writers, both practical and scientific. One class recommend vehemently that manure should be thoroughly rotted in the yard before putting it out on the land, and support their position by arguing that manure is not food for the plant until it is decomposed; also that, when manure is rotted, it requires less labour to haul and spread it, in consequence of the great diminution in its bulk. This latter argument can only count on the supposition that, although the bulk be so greatly diminished, the virtue of the manure all remains, which is most certainly a mistake. Another party advocate putting out the manure while quite fresh or "green," and immediately spreading it on the land. Advocates of both measures point triumphantly to results as conclusive evidence that they are right. It is not to be denied, of course, that a marked effect will follow either course alluded to, especially if sufficient manure be applied; and yet both of these plans are greatly wrong, though partly right. It is quite true that manure is not food for the plant until it is decomposed or "rotted." But, the fatal objection to rotting in the yard is that, by so doing, we lose, say one half, of a valuable commodity. On the other hand, it is true that putting out green manure puts all the constituent elements on the land; yet the following grave objections exist against the plan:—1. It does not increase the manure. 2. It does not improve the quality. 3. It seeds the land with weeds. 4. It does not save labour or time, and may cut the ground up objectionably. But, can a process be suggested which possesses all these advantages without the drawbacks? Yes, I am confident that the following process will meet all objections, and will also increase the bulk of manure; will improve the quality; will kill the weed seeds, without increasing the labour, and will throw much of that work into seasons of the year which are not so precious as that in which yards are usually emptied. The process is as follows:—On the ground where it is desired to have the manure, select an elevated position, and, with the aid of the plough and shovel, make a long, shallow trench, say 6 or 7 inches deep and 2 or 3 feet wide; throw the earth out on the upper side of the trench. This trench may be made at any time, but one must always be prepared just before winter, say in the early part of November. Next, in cleaning the stables, always shovel immediately into the cart or waggon and haul at once to the trench, where it may be dropped in a manner most convenient for covering. Then cover the manure as soon as possible with earth taken from either side of the trench, until the manure is covered with twice its bulk of earth. The drier the earth and the more pulverised the better. Let the earth cover all the manure as effectually as possible, to arrest the gases arising from the decomposing manure. In this state it may stand as long as desired without loss, if the weeds are not allowed to grow on top of it. A month before using it should be examined, and, if not thoroughly rotted, the heap should be lightened up and stirred, to admit air and moisture. When ready for use, the manure has almost disappeared, and the earth having absorbed all the gases evolved in the act of decomposition, has become manure. But, inasmuch as we doubled the bulk of earth to the manure, we have twice as much manure as we had, and moreover we have two loads on the high part of the field for the hauling of one, thus lessening greatly the labour of drawing to the field. Hence it follows that this process pays best where you have to haul farthest and highest; the spreading, being down hill, is easier. The main principle of this process is the well-known quality which earth possesses of "fixing" or holding and retaining gases, a quality now applied beneficially in earth closets, &c. The earth retains these gases, which are the vital fertilising properties, until the plant root comes in contact with it. This fertilising earth is very durable, as "nothing is lost," indeed, its effects have been plainly visible on the spot where it had been spread twenty-nine years before. By this process I conceive that every possible objection in the treatment of manure is obviated, every leak stopped, and every advantage gained. When the compost is thoroughly "cooked" or rotted, the weed seeds must be killed, and the manure is fit food for the plant. It is a manure fit for any or all crops. For ploughing under and top-dressing we have the high authority of Professor Johnston for saying that when a compost is made of more than one constituent, the mass is equal or superior to its best part. From this it would follow that the whole of the compost heap is at least as good as the best ingredient which came out of the stable, and that the quality of the whole is improved. The writer was induced to "work up" this subject many years ago—before earth closets had been heard of—by the great difficulty of procuring sufficient manure to improve his land.—*The Cultivator*.

THE INDOOR GARDEN.

THE FUCHSIA TRIAL AT CHISWICK.

THE following were considered to be the best Fuchsias at the trial of these plants which took place at Chiswick last year:—

ALPHA (G. Smith).—Habit, free and good, very free-flowering; bright carmine tube and sepals, the tubes short and slender, the sepals very broad and short; corolla of immense size, very double, clear violet; one of the very best.

AVALANCHE (G. Smith).—Habit, rather sparse and not very free; tubes, small; sepals, very short and broad for the size of the flower, light rosy-red; corolla, white, exceedingly double and large, and of fine form.

AVALANCHE (E. G. Henderson).—Habit, good and free; tube, slender; sepals, broad, deflexed, scarlet; corolla, deep, full, and even, dark violet-purple; a fine bold variety.

BLUE BEAUTY (Jervis).—Habit, good, compact, free-flowering; tube, short; sepals, broad and short, reflexed, light red; corolla, large, very double, clear purple.

CROWN PRINCE OF PRUSSIA (Veitch).—Habit, dwarf and free, and a free bloomer; flowers, large, the tube bulged, the sepals broad, scarlet; corolla, prominent, dark violet-purple, reddish at the base.

DELIGHT (Smith).—Habit, excellent, and a free bloomer, of first-class merit for decorative or exhibition purposes; tube and sepals, clear crimson, the latter sufficiently reflexed; corolla, very large, pure white, with a few rosy streaks near the base. A really good variety; the best of its class.

LA-FAVORITE (Veitch).—Habit, first-class; tube and sepals, well proportioned, the latter reflexed, scarlet; corolla, large and of good substance, well expanded, light violet. A very free-flowering and good variety.

L'EMPEREUR (Cannell).—Habit, dwarf and floriferous; tube and sepals, scarlet; corolla, single, white.

LUSTRE (Downie & Co.).—Not of free habit; flowers, with blush recurved sepals, and deep-red compact corolla. Approved for its colour.

NOBLESSE (Veitch).—Habit, good and free; flowers, with bright crimson-scarlet tube and sepals, the former slender, the latter spreading; corolla, deep maroon. The darkest-coloured in the collection, and of first-class quality.

RHODERICK DEU (E. G. Henderson).—Habit, good; tube and sepals, bright scarlet, the latter well reflexed; corolla, expanded, lavender-blue.

SCHILLER.—Habit, somewhat loose; flowers, large; the tube and broad-spreading sepals, white-green at the tip; corolla, clear rosy-purple, with white feathers at the base.

STARLIGHT (G. Smith).—A fine variety, not sufficiently known. It has the same habit and the same free-flowering character as Lady Heytesbury, but the corolla is of a bright crimson-lake. It is really a first-class Fuchsia.

VICTOR (Bull).—Habit, strong and compact; very bright scarlet tube and sepals, the latter not much reflexed; corolla of immense size, but coarse and irregular, pale purple, changing to reddish-purple. Not a very desirable Fuchsia.

WAVE OF LIFE (Veitch).—Habit, compact and good; leaves, pale yellow at the points; tube and sepals, bright scarlet, broad and reflexed; corolla, prominent, intense violet, of good substance. A distinct and really good Fuchsia.

WEeping BEAUTY (Veitch).—Habit, dwarf, free, and good; flowers, medium-sized; tube, rather bulged; sepals, broadish; bright crimson-scarlet; corolla, moderately expanded, rich deep purple. A very fine Fuchsia.

WHITE PERFECTION (E. G. Henderson).—Habit, good, floriferous and drooping; tube and sepals, long and narrow, blush-white; corolla large, lake-crimson and rose.

The following is a selection of good and distinct varieties made by Mr. W. Spinks, while foreman at Chiswick and in charge of the plants above described:—

SEpALS AND TUBE WHITE; COROLLA CONTRASTING.—Arabella, Lady Heytesbury, Starlight, free (all dissimilar). May Queen, late Minnie Banks, distinct. Water Nymph, for colour.

SEpALS AND TUBE SCARLET; COROLLA WHITE.—Delight, large single and best. Conspicua, free good single. Puritani, for habit and free-flowering. Alexandrina, extra bright tube and sepals. Avalanche (double, very large), and Enchantress, (double, free-flowering), not of good habit.

SEpALS AND TUBE SCARLET; COROLLA DARK.—Killiecrankie, the most perfect form. Noblesse, the darkest. Weeping Beauty, dark and very fine. Wave of Life, distinct in foliage and good. Sedan, the best-formed red-purple. Monarch, very large and long, distinct.—THOS. MOORE, in the *Journal of the Royal Horticultural Society*.

CATTLEYA MOSSIAE.

This is one of the most showy of all Orchids, and, as it is tolerably reasonable in price as compared with rarer, but less beautiful kinds, it ought to be cultivated as generally as the old *Dendrobium nobile*. It may be grown either in a warm greenhouse or plant-stove, and will grow best in a compost of fibrous Peat and living Sphagnum, to which add sufficient coarse well-washed sand to keep the whole fresh and porous. Drainage is an important point, and the pots must be at least half full of clean crocks, over which place a thin layer of Sphagnum Moss to keep the sand and peat from washing down, and so preventing the superfluous water from passing away freely. As shown in the illustration, the plant should be elevated above the rim of the pot, and, if the Sphagnum is induced to grow freely, so much the better. For exhibition purposes, or for cut flowers, this superb plant is very useful, good specimens bearing from fifty to sixty great broad-petalled flowers, of a deep, rich, rosy tint, the lips being suffused with golden-yellow in the throat, and streaked and veined with dark velvety crimson. This plant is found in almost innumerable varieties in its native habitats, each varying from the other in either size, colour, or markings. If half-a-dozen imported

Cattleya Mossiae.

plants are obtained, it is a great chance if any two of them prove to be alike when they flower, and this fact excites an agreeable curiosity on the part of some amateurs to purchase only imported plants, or plants that have not yet flowered in this country. Some forms are very pale in colour, the sepals and petals being nearly white or pale lilac, while others are of the richest rose-colour, and the lip reminds one of a broad bit of crimson velvet. When in flower, it may be removed to a warm room for a week or two without any fear of injury, and, if the plant is of moderate size, it should be placed under a glass shade, which will not only protect the blooms from dust, but will also cause them to last in beauty much longer by protecting them from the dryness of the atmosphere of the apartment. This last precaution is specially necessary if the room is heated by gas. The plant flowers during the summer months, and generally lasts from two to four weeks in beauty.

F. W. B.

A BLUE PELARGONIUM (?).

"CAN you hybridise *Geranium pratense* with your Zonal varieties?" I asked Mr. Pearson, the famous Zonal Pelargonium-grower. "I think not; but my neighbour, Mr. Lowe, of Highfield House, thinks he can. We will go there and see for ourselves." So off we went next day, and saw Mr. Lowe's wonderful repository for all kinds of curiosities; saw his hybrid seedlings from *Lilium auratum*, which had not yet flowered; saw the yard filled with valuable Lilies, all to be or

being hybridised; and last, not least, his collection of seedling Ferns, which is perfectly wonderful. I believe there are here not less than 15,000 different varieties of English Ferns, nearly all raised from seed, many of them being varieties only in a connoisseur's eyes. There are Ferns lovely, Ferns ugly, Ferns like fairy dreams, and Ferns like grim nightmares; Ferns tall, crested, broad, narrow, long, short, curled, straight, twisted like Mosses, or split up into fronds as delicate as the Maiden-hair, and as unlike their normal form as anything can be. There are few horticultural sensations so great as the variety of Mr. Lowe's Ferns. He is certain that he has succeeded in raising crosses between different Ferns by sowing the spores mixed together, and some of the odd seedlings which he showed us seemed to confirm his statement. "My friend wants to see," said Mr. Pearson, "if you have hybridised the blue *Geranium* of the fields with the Zonal. Have you done so?" "Undoubtedly. Come and look." And we saw a great number of seedlings raised from the blue *Geranium* crossed with Madame Vaucher, a well-known white Zonal. Most of these in no way differed from the female parent, with one striking exception, which was a small plant with little leaves, almost like those of a show *Pelargonium*, and with flowers having the narrowest petals imaginable, which were of a bluish-pink tint. The whole plant resembled somewhat the old pink bedder, Lady Cullum, except that its petals were very much smaller than I have ever seen in any *Pelargonium*, seedling or otherwise. Of the seedlings raised from the Zonal for the female fertilised with the blue *G. pratense* there was a large frameful, nearly all of which showed more or less inclination to the deeply-cut leaf of the male parent. One plant in particular differed but little from *G. pratense*, and most of the flowers showed traces of blue; some, however, were red, a curious fact, as the female parent was again Madame Vaucher. Nearly all the flowers were very small, and generally extraordinarily narrow-petalled. In the end, both Mr. Pearson and myself came away convinced that these were true hybrids, for, as Mr. Pearson remarked, "there can be no other way of raising such extraordinary varieties." My reasons for wanting to know how Mr. Lowe's experiments had succeeded are these. I have been trying for three years, quite independently of any one else, to raise a cross between these two plants. My first year was quite unsuccessful. The year before last I crossed, as I fully believe, a Zonal, with a bluish tinge in it, named Lawrence Heywood, with *G. pratense*. Only four seeds ripened, which came up when I was away, as I generally am, and, I suppose, consequently damped off. So, last summer, I set to work again, and crossed several Zonals with *G. pratense*; every cross took, and I waited for the store of seeds to ripen, which they did with a vengeance; for one sad morning I found all my seeds had scattered themselves, and been irretrievably lost; luckily three were still discoverable; these I sowed, and, after six months' waiting, one seedling is putting in, or rather out, an appearance in a small saucer in my greenhouse. It has cotyledons similar to those of *G. pratense*, and promises soon to exhibit its first leaf. I am aware that many of our great horticulturists, Major Trevor Clarke for example, have said that there can be no true hybrid as I have described. I know little of botany; nevertheless, I believe, after my second experiment, that it could be done, and in this I am confirmed by Mr. Pearson, who is one of our best hybridisers. Whether we shall ever have a blue Zonal *Pelargonium* or not is another matter, and on which some of your readers can possibly throw some light.

FRANCIS MILES.

Bingham, Notts.

CLEMATISES IN POTS FOR EARLY FLOWERING.

THE Clematis has been produced of late in so many new, varied, and beautiful forms, that those having only a superficial knowledge of them find it very difficult indeed to make a selection. The various types have recently been grouped under several divisions or sections, but each of these contains so many varieties constantly receiving accessions of new ones, that the difficulty of selecting remains as great as ever. The Clematis deserves to be, and should be, as common in our gardens as the Rose, which may be taken as the typical popular flower. It is as hardy as the queen of flowers, and as easily managed. The main purpose of this paper is to show that the varieties of two of the sections of Clematises—viz., the patens type and the lanuginosa

type—are specially adapted for early flowering in pots; and there is no glass structure that will grow plants, however homely in design and rude in character, but can be made very gay by means of freely-bloomed Clematis in pots during the early summer months. In cold, late districts, where the vegetation is apt to suffer from the late spring frosts, it is scarcely safe to plant in the open air the early-flowering Clematises of the patens type, as they are very apt to be injured by frost. It has frequently happened that in late districts these early Clematises will develop their flowers, and then in one night a cutting frost will work them irretrievable injury. Granting that such an instance as this may be exceptional, yet it may frequently occur, and, therefore, it is wise to grow a few plants under shelter, especially of the newer and rarer varieties. Of the patens group, that is, those Clematises which flower from the old or ripened wood, the following can be recommended for their great beauty, distinctness, and decorative value; Albert Victor, deep lavender, with a pale bar along each sepal; Lady Londesborough, silver grey, with pale bar; Lord Londesborough, delicate mauve, with pale claret bar; Patens, delicate mauve-lilac, very free and effective; Miss Bateman, white, with chocolate-red anthers—the best white Clematis in cultivation—Sophia plena, lilac-purple, double; and Standishii, light mauve. All the foregoing produce large finely-formed flowers, with considerable freedom, and, when cultivated under glass, the flowers are prolonged for a lengthened period, as they are preserved from the effects of wet and frosty weather, and from the ravages of the wind. The varieties of the patens section just enumerated will come into bloom before the varieties of the lanuginosa section, because the latter flower from the young growth of the same year, and are, in consequence, later. Of the lanuginosa group, which now includes some very fine and valuable varieties, the following should be grown—Aureliana, porcelain blue; Gem, deep lavender blue; lanuginosa, pale lavender; lanuginosa nivea, pure white; and Otto Fröbel, greyish-white, very large, and finely formed. According to the size of the plants should be the pots in which they are placed; but 24's for the small plants, and 12's for the large ones will be found amply sufficient. Let it always be borne in mind in planting the Clematis, whether in pots or in the open ground, that it develops a large number of strong succulent roots that are strong feeders, and require liberal nutriment from which to draw the needful supplies for the plant. These succulent roots go down to the bottom of the pot, and form a dense mass; therefore, it is absolutely necessary that some very rich soil be used at potting time. Equal quantities of good loam and thoroughly rotten manure will suit the Clematis well; and, when potting, plant nearly up to the rim of the pots, leaving room for water. The flowers are thrown out on shortish stems, producing two, or three, or more from the buds, which are put forth from the old or ripened wood; and, at the same time, there will come up from the base of the plant sturdy young shoots, which will form the flowering-wood of the following year. It will be necessary to provide some appliance to which the blooming wood can be tied out and the young growth trained. There is nothing like wire frames, of oval or rounded shape; but, failing these, a stout stake placed in the middle of the pot to support the plant, or some slighter stakes placed round the pot, will do equally well. The growing wood should be kept tied to the main stake, so as not to impede or hide the expanding flowers. In the case of lanuginosa and its varieties, the young growth should be trained so as to become equally distributed, and afford a good surface of flower. There must be no lack of water, for the Clematis likes and should have plenty of it, and especially manure-water when the plants are in bloom. As soon as the plants have done flowering, remove them from the house, and plunge them in a shady border up to the rims of the pots, or stand them away under a hedge where they can ripen their wood, and remain till they are wanted for re-potting in November and December, when the plants should be pruned. In the case of the patens section, cut away only the weak, straggling, or overcrowded branches. All the strong wood of the previous summer should be left, in so far as it has become thoroughly ripened, beyond which it may be cut away. In the case of the varieties of the lanuginosa section, but comparatively slight pruning is required. In Moore and Jackman's book on the Clematis, it is stated that "the type itself, and those varieties which come nearest to it in habit, indeed, die back almost sufficiently to render pruning unnecessary; but, in those instances where a mixture of blood has led to a more extended growth, it will be necessary to cut so as to remove the weakly and ill-ripened portions of the year-old wood. Under favourable conditions, the plants will make an annual growth of from 8 to 10 feet in length, and of this, the unripened extremities, together with the weak or superfluous shoots and the dead wood, are the only parts which ought to be removed." Lastly, during the time the Clematis is making its growth, give abundance of air on all suitable occasions, and syringe the plants freely in bright weather. R. D.

Cœlogyne cristata.—Mr. Tanton has stated (see p. 10) that *Cœlogyne cristata* is a native of Guatemala, and that it was introduced by Hartweg. I had always understood that it was discovered by Dr. Wallich, about 1832, in Nepaul, and afterwards by Dr. Hooker, in Sikkim, growing on mossy rocks and trees, at an altitude of from 5,000 to 8,000 feet; consequently it comes from a very cool temperature, though exposed to a hot sun. Having been a long and considerable grower of this *Cœlogyne* I have been frequently asked from whence it was brought, and the invariable reply has been in accordance with the facts just stated. I was, therefore, astounded at Mr. Tanton's statement that it came from Guatemala. If he will refer to Warner and William's folio work on Orchids he will there find the authentic references, Lindley, Wallich, Hooker, and others. Mr. Gibson, if I am not mistaken, informed me, when he was at Chatsworth, that, during his three years' exploration of upper or northern India, he collected and brought over, amongst other priceless discoveries, a number of bulbs of this useful Orchid, which he himself had gathered in Nepaul. If Mr. Tanton will consult his gazetteer he will find that Guatemala is not a province of, nor in, Mexico, but an independent republic of central America, lat. 13 to 18 N., climate hot and unhealthy in the valleys. Nepaul and Sikkim are from 5,000 to 8,000 feet above the sea-level, lat. 26° to 30° N., climate, cool and moist.—RICHARD S. YATES, *Cheshire*.

Pitcher Plants.—From the peculiar habit of these plants they are exceedingly susceptible of injury from the slightest touch of the hand, a circumstance worth remembering by those who have them under their care. No Pitcher plant will long remain in a healthy state if the foliage be allowed to be frequently handled. The *Nepenthes distillatoria*, or common Pitcher plant, succeeds best in Moss chopped rather fine, mixed with white sand and a little peat; and it will be found of great assistance in promoting the vigour of the plant, if a little additional Moss be added to the surface from time to time, as the plant advances. The roots of the *Nepenthes* never run deep, whatever the compost may be in which they are planted, but invariably spread themselves over and about the surface of the Moss. They require to be kept moist, but, unless when the plants are growing very vigorously indeed, setting them in feeders of water is injurious to them. This plant is far from tender. In the Edinburgh garden a plant was exposed to 8° of frost; it was afterwards removed to the stove, without suffering any injury from the frost to which it had been exposed. It, however, usually succeeds best when kept in a heat ranging from 60° to 80° of Fahrenheit. It is not difficult of increase by cuttings.—J. H.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Lapageria rosea.—Will any of your correspondents who have had experience in a similar case tell me if it will answer to cut down a large plant of *Lapageria rosea*, on a trellis, which is getting rather naked at bottom? The plant in question grows strongly enough from the top, but has not pushed a shoot from the bottom for four or five years, though there are six or seven strong, long shoots buried in the soil curled round the inside of the tub.—G. W.

Green "flowered" Pelargonium.—A very singular *Pelargonium* was raised in 1870 by M. Pescatore, of Villafranca, and named by him *P. zonale lycopodioides*. Its peculiarity consists in the circumstance of all the flowers being transformed into dense longish tufts of narrow green bracts, presenting the appearance of the extremities of the branches or shoots of a *Lycopodium*. In foliage and other respects, the plant does not differ from an ordinary *Zonal Pelargonium*. This monstrosity is described, and well shown in a wood engraving, in the last number of the *Revue Horticole*.

Venus's Fly-trap.—No. 147 of the *Proceedings of the Royal Society* contains Professor Burdon Sanderson's note on the Electrical Phenomena exhibited by Venus's Fly-trap (*Dionæa*). The blade of the leaf is found to possess a current proceeding from base to apex, but what is very remarkable is that the stalk contains one which proceeds in the opposite direction. The result of snipping off successive portions of the stalk is to increase the effect upon a galvanometer of the current in the blade. When the blade is irritated, the blade-current appears to be diminished, at first momentarily (but afterwards to be slightly augmented); correspondingly the stalk-current appears to be intensified.—*Academy*.

Odontoglossum coronarium.—This fine Orchid first flowered in this country in Lord Londesborough's collection at Grimston Park, where it bore eighteen flowers on a spike, and shortly afterwards it bloomed in Mr. W. Bull's collection at Chelsea, where it bore between thirty and forty blooms on a spike. More recently, a plant of it has borne two flower-spikes in Mr. Wrigley's fine collection, at Bridge Hall, where the smallest spike bore twelve and the larger one twenty-four blooms. This last is the best bloomed specimen in this country of which we have any record. Mr. Wrigley has kindly sent us a photograph of his plant taken while in bloom, and which shows it to have been very effective, the noble spike of flowers standing perfectly perpendicular, well up above the foliage.

Packing Plants to Travel long Distances.—In packing plants for transmission to distant places, there is more danger from too much than from too little moisture. The best packing material is Sphagnum, or bog Moss, and this should be just so damp only as to be elastic to the touch. Plants packed in this, if not too damp, will remain for weeks uninjured; that is, if the plants are at rest. Another thing is to pack close. If sending by post, take a piece of strong brown paper; lay the just damp, not wet, Moss upon it; put the plants upon the Moss, and more Moss over the plants. Then begin at one end of the paper and roll up hard, secure with a string, and then put another paper over for directions. So, in packing in boxes, use the Moss just damp, and have the box full and crammed down hard, so that there can be no possibility of moving or shaking in transit.—Dr. THURBER.

THE ARBORETUM.

HARDY TREES AND SHRUBS.

By GEORGE GORDON, A.L.S.

THE ATHENIAN MAPLE (ACER ATHENIENSE).

THIS kind forms a tree 30 feet high, with the main stem rising straight up and regularly furnished on all sides with rather stout, open, and somewhat ascending branches, covered with a smooth ash-coloured bark. It is said to be found in the neighbourhood of Athens, and was first introduced in 1849 from the nursery of M. Van Houtte, in Belgium. The leaves are palmately five-lobed, nearly square or very slightly cordate at the base, quite smooth on both surfaces, on very long and rather slender foot-stalks, light green above, pallid beneath, and just before they fall off in the autumn turn to a pale yellow or light brown colour. The lobes are ovate-pointed with angular recesses, the three outer ones being the largest and nearly equal in size, and, with the exception of a pair of short angular blunt semi-lobes on each, quite entire on the edges. The flowers are rather small and in loose racemes. The fruit or keys are rather large, with widely diverging wings. Length of the leaf, 8 inches, including the foot-stalk (which is from 4 to 5 inches long), and the breadth 5 inches.

THE REDWOOD.

(SEQUOIA SEMPERVIRENS.)

MANY of our readers are familiar with young specimens of Sequoia or Taxodium sempervirens, the Redwood of California, but few have any idea of the enormous importance and great size of the tree. These facts may not be without importance to us, even from a commercial point of view, as the tree does very well in sea-shore districts in the southern parts of England and Ireland. The most notable fact about the tree is, that it is quite as great in stature as the "Big tree," or Wellingtonia. And, though not so large in the bole, it is nevertheless a large tree. One peculiarity of the tree is, that its wood may be made into planks without the aid of the saw—split, in fact, by means of wedges. One of the best recent additions to our knowledge of this tree is from the pen of Mr. Charles Nordhoff, who contributes a good deal of interesting matter about northern California to *Harper's Magazine*. In the coast counties of this region he finds the famous Redwood forests, "whose trees are unequalled in size, except by the gigantic Sequoias;" "and on this coast saw-mills and logging-camps, where the immense Redwood forests are reduced to useful lumber, with a prodigious waste of wood." The saw-mill country begins at the mouth of Russian River, and they are placed at the mouths of all these streams, and wherever a river-mouth offers the slightest shelter to vessels loading; for the Redwood forests line the coast up to, and beyond, Humboldt Bay. There are even mills which offer no lee to vessels loading; and here the adventurous schooner watches her opportunity, hauls under a perpendicular cliff, receives her lading in the shortest possible time, and her crew think themselves fortunate if they get safely off. It is in the logging camps that a stranger will be most interested on this coast; for there he will see and feel the bigness of the Redwoods. A man in Humboldt County got out of one tree lumber enough to make his house and barn, and to fence in 2 acres of ground. A schooner was filled with shingles made from a single tree. One tree in Mendocino, whose remains were shown to me, made a mile of railroad ties. Trees 14 feet in diameter have been frequently found and cut down; the saw-logs are often split apart

with wedges, because the entire mass is too large to float in the narrow and shallow streams, and I have even seen them blow a log apart with gunpowder. A tree 4 feet in diameter is called undersized in these woods; and so skilful are the wood-choppers that they can make the largest giant of the forest fall just where they want it, or, as they say, they "drive a stake with the tree." The choppers do not stand on the ground, but on stages raised to such a height as to enable the axe to strike in where the tree attains its fair and regular thickness; for the Redwood, like the Sequoia, swells at the base, near the ground. These trees prefer steep hill-sides, and grow in an extremely rough and broken country, and their great height makes it necessary to fell them carefully, lest they should, falling with such an enormous weight, break to pieces. This constantly happens, in spite of every precaution, and there is little doubt that in these forests and at the mills 2 feet of wood are wasted for every foot of lumber sent to market. To mark the direction line in which the tree is to fall, the choppers usually drive a stake into the ground 100 or 150 feet from the base of the tree, and it actually is common to make the tree fall upon this stake, so straight do these Redwoods stand, and so accurate is the skill of the cutters. To fell a tree 8 feet in diameter, is counted a day's work for a man. When such a tree begins to totter, it gives at first a

sharp crack; the cutter labours with his axe usually about fifteen minutes after this premonitory crack, when at last the huge mass begins to go over. Then you may hear one of the grandest sounds of the forest. The fall of a great Redwood is startling, like a prolonged thundercrash, and is really a terrible sound.

The Government has lately become very strict in preserving the timber on Congress land, which was formerly cut at random, and by anybody who chose. Government agents watch the loggers, and, if these are anywhere caught cutting timber on Congress land, their rafts are seized and sold. At present prices it pays to haul logs in the Redwood country, only about half a mile to water; all trees more distant than this from a river are not cut; but the rivers are in many places near each other, and the belt of timber left standing, though considerable, is not so great as one would think. Redwood lumber has one singular property—it shrinks endwise, so that where it is used for weather-boarding a house, one is apt to see the butts shrunk apart. I am told that across the grain it does not shrink per-

Leaf of the Athenian Maple.

ceptibly. Accidents are frequent in a logging-camp, and good surgeons are in demand in all the saw-mill ports, for there is much more occasion for surgery than for physic. Men are cut with axes, jammed by logs, and otherwise hurt, one of the most serious dangers arising from the fall of limbs torn from standing trees by a falling one. Often such a limb lodges or sticks in the high top of a tree until the wind blows it down, or the concussion of the wood-cutter's axe, cutting down the tree, loosens it. Falling from such a height as 200 feet or 250 feet, even a light branch is dangerous, and men sometimes have their brains dashed out by such a falling limb. When you leave the coast for the interior, you ride through mile after mile of Redwood forests. Unlike the Firs of Oregon and Puget Sound, this tree does not occupy the whole land. It rears its tall head from a jungle of Laurel, Madronæ, Oak, and other trees; and I doubt if so many as fifty large Redwoods often stand upon a single acre. I was told that an average tree would turn out about 15,000 feet of lumber, and thus, even thirty such trees to the acre would yield nearly half a million feet.

The Beech Blight.—A Beech-tree here, on high ground looking over the "Downs," has, for the last two years, been covered with a snow-white down, extending from the trunk to some of the branches.

I see in your last number (112), a paragraph headed "A New Blight," which corresponds very much with the one which has attacked our tree. Beech-trees, as a rule, grow very well, and the one mentioned is the only one attacked, although there are more close by. I should feel much obliged if you would give me any hint as to the destruction of this blight. The tree in question has not shown any symptoms of decay.—J. H. MONIUS. [The snow-white downy secretion on his Beech trees which your correspondent ("J. H. Monius") has sent for examination, and which, as he suggests, is, no doubt, the so-called "New Blight" quoted in last number of THE GARDEN, as attacking the Beech trees, in Westphalia, is neither new nor (unhappily) rare, nor have we any difficulty in saying how it got there. It is the excretion with which a species of the Coccus family, named *Adelges fagi*, covers itself, sometimes in such quantity as to cause the stems of the trees to look as if whitewashed. Foresters are familiar with two other species of the same genus, which, like this, covers the stems of two other trees with a similar white excretion, the one the Silver Fir, and the other the Weymouth Pine. I remember, some twenty years ago, consulting the late Mr. Charles Macintosh, author of the "Book of the Garden," as to the best mode of dealing with one of these. It was that which attacks the Silver Fir, but it does not matter which species it was, for all have the same habits, and whatever is good or bad for one will be so for all. His advice was to cut down every tree that was attacked, or it would spread, and, if it once established itself, it would destroy all the Silvers round about. I unwisely, and too credulously, acted upon his advice, all the trees were carefully examined, and wherever one was found with the *Adelges* on it, down it went; fresh researches produced fresh victims, until I awoke to the conviction that if I went on at that rate I would have to cut down all my trees to preserve them; and, as if they were to go, it mattered little whether they were cut off by disease or the axe, I came to the conclusion that I had better let them die by the slower process of natural death, and, at least, enjoy their beauty so long as it lasted. Unhappily I had been rather long in coming to my senses, and the Silvers about the place had been reduced by the stamping-out process to a very few. Few as they are, however, there they still remain, and, to all appearance, not a whit the worse of the *Adelges*. It still sticks to them, but in smaller numbers, and the antidote seems to have followed the disease without any trouble on my part. The last time I looked at them I was not surprised, but interested, to see great numbers of the larvæ of the lady-bird (*Coccinella*) so like the bark of the tree that the eye could scarcely distinguish them until they moved, busy promenading about among the *Adelges* pouncing upon them and sucking the life blood out of hundreds, if not thousands, every day. The result of this would, no doubt, be to keep them in check, and the proof that they had done so was that the *Adelges* are in smaller numbers and the trees more healthy than they were for twenty years. Your correspondent will see that he has no reason to be very anxious about his trees, but I would recommend his rubbing the stems, where they are infested, with a coarse nail-brush made of cocoa-nut fibre (to be had for 3d.) He may wash them at the same time with Gishurst compound, or any other sulphur-soap, but the rough friction is the thing, and the object is to kill the insects by crushing them through rough-handling. They are soft and tender, and chiefly (although by no means entirely) congregate on the stems, which makes it easier to get at and rid of them.—ANDREW MURRAY.]

THE KITCHEN GARDEN.

CULTURE OF PARSLEY.

PARSLEY will grow in almost any kind of soil; nevertheless, there are few plants that will pay better for a little extra care and attention being bestowed upon them. The greatest mistake committed in regard to its culture is thick sowing and want of timely thinning. Give it room enough, and plenty of fine curled leaves will be the result. Even a really good curled Parsley, if grown too thickly, will, in a measure, lose its improved character. Let any one notice the difference between the development of a chance stray seedling where it has had plenty of room to grow, and the puny weakly growth of the thickly-sown unthinned bed, and the truth of this statement will be at once apparent. If there is likely to be any scarcity of Parsley during the spring months, a box of it may now be sown and placed in any warm house or frame near the glass, in due course to be hardened off and transplanted at the foot of a south wall, 6 inches apart; this will come in for early picking. In February, when the ground is in nice working condition, having been manured and deeply stirred, and exposed to the

mellowing influence of frost, a good large sowing should be made; at least, large in proportion to the demand, as it is always best to err on the right side. And, as Parsley is wanted daily, let it be sown in some spot that is easily accessible. Sow thinly in drills a foot apart, covering the seeds about half an inch deep. In heavy soils there is sometimes a difficulty in getting small seeds to vegetate quickly in ungenial seasons, and in such cases I have found a great advantage in covering seeds in drills, with half an inch of the sifted ashes from the bottoms of heaps, where fruit-tree and other prunings, cuttings and rubbish generally have been burned. When clearing the rubbish-yard it is easy to lay a heap of this kind of material on one side, and there is always a lot of cuttings and other matters in every garden, that are best smothered and burned, if I may so term it: to burn all up to fire ashes is a wasteful method. Commence by making a fire with the sticks and other inflammable matters, and, when well established, gradually place on it Cabbage-stalks, weeds, &c., and, if the sub-soil is of a clayey nature, dry lumps of that may be piled up round and over the heap. Care must, however, be taken not to load it too heavily, or the draught will be stopped and the fire put out. This not only makes a capital compost for covering seeds, but also for renovating an exhausted soil, or rendering a heavy one more workable. As soon as the young plants are up, run the Dutch hoe through them, and, when two inches high, thin them out to six inches apart, to be ultimately, early in July, thinned further to one foot apart, and the plants so thinned out ought to have all the large leaves cut off and be planted in a warm sheltered corner for late autumn and winter supply, where they may be easily covered up in bad weather. I have always found Parsley transplanted in July, after having most of the leaves cut off, stand the winter better. It is, however, not wise to depend altogether upon the outdoor supply. It is always best, in addition, to have some in reserve under glass, for very severe weather; it may be in pots or boxes, if a whole frame cannot be spared for it. A few roots lifted in September will come in very usefully during severe frost. Another small sowing should be made towards the end of July. This latter sowing will be found especially useful during the following summer, as it will not run to seed so soon as the earlier-sown crops.

E. HOBDAY.

Cauliflower and Broccoli.—These are always in demand, and, happily, either one or the other may be had in season the whole year round—i.e., where anything like proper attention is paid to succession-cropping. For all early crops of Cauliflowers to furnish the summer supply, the soil can scarcely be too rich or highly cultivated; but, for all late crops of Cauliflowers and all Broccoli crops, great saving of labour with good results may be effected by proceeding as follows:—As the early Peas, Potatoes, &c., are cleared off, do not either dig or fork the ground, as the firmer it is the better. The system, if the weather is very dry, is to draw drills deeply, and to water them with water until the ground is thoroughly soaked. Then plant immediately; give another good watering, and draw some dusty soil over the portion wetted, in order to prevent evaporation. The advantages of this plan over that of digging the ground first are that the plants will be rooted and growing in much less time; scarce any go blind, the growth will be sturdier, and better able to resist extremes of temperature, and the flower will keep far longer in a good condition for table than in the case of plants treated otherwise, while the labour thus saved can be more profitably employed; and last but not least, the best roots of choice fruit-trees growing near will not be disturbed.—JAMES GROOM, *Henham Gardens, Suffolk.*

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Seeds and Mice.—To keep seeds from the depredations of mice, mix small pieces of camphor-gum with the seeds. Camphor placed in drawers or trays will prevent mice from doing them injury.—C.

Protecting Endive.—I have at this moment some hundreds of heads of this useful winter salad plant plunged under cloths and well secured against frost by the simple process of plunging their roots in sawdust and ashes, with slight sprinkling of powdered charcoal. The roots outside are covered with dry Fern, kept on the plants by small pieces of old rails.—Q.

Red Celery.—I have last year tried Major Clarke's Vandy, Lettuce, Cole's and Wyatt's Red Celery, against my old tried friend Williams's Maudslayi supplied by Messrs. Barr & Sugden, and find it still the best of them all. I shall this year, unless, perhaps, a row or two for trial, grow only Williams's Matchless.—R. GILBERT, *Banbury.*

THE AMATEUR'S GARDEN.*

HINTS ON HYBRIDISING.

NEW flowers produce an indescribable pleasure, and it is one which anyone with a garden, or even a few pot plants in a window or cool frame, may enjoy. In some parts of Lancashire and the north of England, Auriculas, Tulips, Pansies, Hollyhocks, and other hardy flowers are much grown by working men or artisans, and some of the finest show varieties of these flowers have originated in cottage gardens. Even the colliers in many of the midland districts grow enthusiastic when dilating on the properties of some new florists' flowers which they have raised, while the numerous skilled artisans in towns, such as Coventry or Nottingham, are well known as most excellent cultivators of nearly all kinds of hardy vegetables as well as florists' flowers. In the raising of new varieties, there are a few leading principles which must be borne in mind; for example, species or varieties of the same genus can only be crossed with each other with advantage; and, if possible, always make the best-habited plant the seed-bearing parent. A plant of bad general habit or weak constitution often bears a richly-coloured or finely-formed flower, and by crossing this with another variety, perhaps possessing poor flowers but a robust constitution, an improvement on both parents may be looked for among the seedlings. The operation of crossing, or, more properly speaking, fertilising, one flower with another, is simple enough, all that is required, as a rule, being two parent plants in such a condition as to enable the operator to convey the pollen of one flower, or

Fig. 1. Portion of the style and stigma magnified, showing pollen tubes forcing their way down the style. 2. Pollen grain magnified, emitting tube. 3. Stamens and stigma of Wallflower, magnified. 4. Magnified anther of same, showing the pollen grains at *p*.

variety, to the tip of the style or stigma of the other. This operation can be effected readily by means of a moist camel's-hair brush or pencil. Some plants cannot be fertilised with pollen from their own flowers; but there are others that are much too susceptible of fertilisation, and this often puzzles amateurs, who imagine that they have crossed flowers with the pollen of another form, when the same have been fertilised with their own pollen days before, and, consequently, the result is disappointing. In order to prevent this, it is well to clip off the anthers or little cases that contain the pollen of the seed-bearing plant directly the flowers expand, taking care not to cut or bruise the stigma when so doing. For the latter process, a pair of small sharp-pointed scissors is the best. The action of the pollen on the stigma is very singular and interesting, and is well illustrated in our engravings. The pollen grains, soon after being placed on the glutinous apex of the style, throw out slender tubes, which pass down the loose cellular tissue of the style until they reach the embryo ovules, or seeds, contained in the ovary or seed-vessel below. Having reached these, and fertilised them by emitting the fluid contents of the pollen grain above, their use ceases, and they soon become dried up, together with the superfluous end of the style, while the young seeds, or such of them as have come in contact with the pollen tubes begin to swell and ripen. In some cases only one or two out of the twenty or thirty embryo seeds in each seed-vessel become fertilised and swell off, while the others come to nothing. A

very little practical experience will enable any one to fertilise and raise seedlings from their favourite flowers, while researches in this way may lead to valuable results. Comparatively few horticulturists have as yet devoted themselves to hybridisation, and yet the results obtained are very remarkable. We have only to look at the new Peas of Laxton or Dr. M'Lean, the Orchids of Dominy, or the many beautiful varieties of Cyclamen, Pelargonium, Gladioli, Asters, and other florists' flowers now common in our gardens, in order to fully recognise the beneficial results which are to be obtained by studying and working out this subject as far as means will permit. To be able to render a flower more beautiful, or to enhance the excellence, or ameliorate the flavour of a new fruit or vegetable, is something worth attempting, as such a result not only benefits its producer, but is the means of handing down to posterity a great and lasting good. J. W.

FERNS FOR A COOL HOUSE.

SURELY your Manchester correspondent (see p. 66) must have been led into some mistake when he recommends the hardy *Osmunda regalis*, *Filix-fœmina*, *Onoclea sensibilis*, *Polypodium cambricum*, *Scolopendrium vulgare*, or even the grand *Cyrtomium falcatum*, to be grown in a heat in which *Dendrobium nobile* can exist. I venture to add the names of a few Ferns that appear to me more worthy of culture in heat, all of which ought to thrive in the house described by "R. H.," viz., *Adiantum assimile*, *A. concinnum*, *A. concinnum latum*, *A. chilense*, *A. cuneatum*, *A. rubellum*, *A. pedatum*, *A. tenerum*, *A. trapeziforme*, *A. macrophyllum*, *Asplenium marinum*, *A. viviparum*, *Cheilanthes elegans*, *C. hirta*, *Lygodium scandens*, *Pteris tricolor*. Several of the hardier *Davallias* and some of the *Todeas* would also thrive, with many others whose names do not at the moment occur to me. W. C. M.

WORK FOR THE WEEK.

PRIVATE GARDENS.

Conservatories.—Arrange fine-leaved plants, such as greenhouse *Dracænas*, *Yuccas*, *Beaucarneas*, *Grevilleas*, *Tree-Ferns*, and other foliage and flowering ones together effectively and harmoniously. Remove plants done flowering, and introduce a fresh supply from the forcing pit. Give a little weak manure-water to *Cyclamens*. Keep late ones close to the glass in frames free from drip, and sow some seeds of *Cyclamens* in an intermediate house, if not previously done. Prick off October and November sowings into pots, or pans, filled with light soil, putting several plants in each, and allowing them to remain there until their leaves meet one another, when they should be potted singly into 60-sized pots. Sow also a few seeds of East Lothian Stock; keep autumn-potted Stocks in cold frames, and pot off a few of them singly. Pot any *Calceolarias* or *Cinerarias* that may require it, using a rich compost for them, and keep them rather close for a short time, but they should always be in cool houses or pits, and near the glass. Prune a few more pot *Roses*, and place them in a forcing house or early Peach-house to induce them to come into bloom. In early Fig-houses, or other fruit-houses, not too much shaded, many flowering plants may be brought into bloom, either for conservatory decorations or for cut flowers. *Rhododendrons*, *Roses*, *Callas*, *Tree-Carnations*, *Heliotropes*, *Mignonette*, *Lily of the Valley*, *Tulips*, *Hyacinths*, *Narcissi*, *Kalmias*, *Jasmines*, *Weigelas*, *Prunus sinensis*, *Lilacs*, *Ghent and Indian Azaleas*, *Camellias*, *Fuchsias*, *Hippeastrums*, *Hæmanthus*, *Violets*, *Pelargoniums*, and several other plants might be brought to the flowering stage in early fruit-houses, and afterwards removed to the greenhouse. Such as are soft-wooded should be kept as near the glass as possible, and hard-wooded deciduous plants should be placed by themselves, so that they can be freely syringed. *Violets*, if planted out in frames on a bottom-heat, afford more flowers than under any other circumstances. Proceed with the staking and tying of specimen hard-wooded plants, such as *Boronias*, *Croweas*, &c. Keep *Heaths* in the freest ventilated portion of conservatories, water them moderately, and neatly stake them. Remove plants of *Solanum Capsicastrum* when the berries begin to drop, or shrivel, and save a few of the best berries for seed. Remove all damping or decaying leaves, and use every means at command for keeping down insects. The old plants, too, may be saved for next year's blooming, by placing them under the stages, or in frames, keeping them moderately dry for a time, then pruning them back pretty closely, and planting them outside in a rich border in May,

* This department is written exclusively by amateurs distinguished for skill in various branches of gardening.

when they are permitted to grow, flower, and form their berries, and are then lifted, potted, and introduced into the frames or greenhouses. A few of the earliest-rested plants of Fuchsias, and Lemon-scented Verbenas may be pruned a little, and started in a genial warm temperature; just give the others enough water to keep the soil from being dust-dry. A few plants of *Lilium auratum* may now be brought into an intermediate house to start; great care being taken in watering, until the shoots have emerged some inches from the soil.

Stoves.—Allamandas, Bougainvilleas, and Clerodendrons (climbing ones) should be cut back at once if not already done, and re-potted very firmly as soon as convenient, using good loamy soil, enriched with a little decayed manure, but not encouraged to make growth. Keep the soil pretty dry, even after potting, insert the principal stakes, and preserve the young growths from getting broken. Plants of Poinsettias and *Euphorbia jacquiniæflora* done blooming should be stored away on back shelves, under the stages, or in any other place where they can be kept dry in an intermediate house or the coolest end of the stove. *Aphelandras* done flowering may be treated in the same way, and those coming into bloom should have plenty of water, and a position near the glass. Do not allow any young plants to suffer from want of root room, but give them a shift as soon as they require it. Of stove bulbous plants at rest, start a few into growth, for early use, but it is too soon yet to start the general stock of these. A few *Amaryllises* should be introduced to a moist brisk temperature, to encourage them to bloom early. Attend to the eradication of all winter pests, and to the staking and tying up various sorts of plants.

Orchids.—From amongst these the warmest nooks in our conservatories are being supplied with their most showy flowers. *Oncidiums*, *Odontoglossums*, and *Cœlogynes* are in great beauty, and these, together with *Phalænopsids*, furnish masses of white flowers, orange and crimson and allied colours being furnished by *Masdevallias*, *Adas*, *Sophronitis*, *Epidendrums*, *Barkerias*, &c., whilst *Cattleyas*, *Vandas*, *Saccolabiums*, *Lælias*, *Dendrobiums*, *Phajus*, *Restrepias*, &c., afford an immense variety of both colour and form. Prepare materials for a general potting next month and the succeeding one. Begin to pot, as soon as practicable, *Odontoglossums*, *Miltonias*, *Masdevallias*, &c., and those not requiring this at present should be top-dressed. Any bulbous *Calanthes*—those of the *vestita* section—not yet placed at rest, should be laid on their sides and kept dry. As soon as any appearance of growth presents itself in the earliest rested plants, re-pot them, and place them under growing conditions. Give the terrestrial *Calanthes* plenty of water when they require it, and if they are in vigorous condition a little weak manure-water will be very beneficial to them. *Dendrobium nobile* being now, as a rule, well set with flower-buds, may be forwarded by introducing some plants of them into a brisk temperature, and others may be retarded by keeping in rather a cool house or pit. Attend to the destruction of all kinds of insects, as their numbers can be more easily and conveniently reduced than later on in the season. Scale, green fly, thrips, ants, mealy bug, red spider, woodlice, and wire-worms require attention. Keep *Pleiones* in a nice growing state; any of the varieties that have not finished blooming should be re-potted as soon as their last flowers are past. Maintain a moderately moist atmosphere in all the Orchid houses, otherwise *Phalænopsids* and other long aerial-rooted species will suffer.

Hot-beds.—Prepare materials at once, consisting of cleanly-collected leaves, and rank, but well-moistened, stable litter, for the construction of these. In making a hot-bed, have a good wide foundation marked by inserting some strong stakes in the corners, for by these stakes the plumb, and height of the beds, too, can be determined. The foundation should consist of a layer of brush-wood, over which *Asparagus*, *Bean*, and *Pea* haulm should be placed, and fermenting material firmly built over that, being careful to make it firm by beating with the fork in preference to much trampling, and leaving sufficient space on either side of the frames for the convenience of linings. One made immediately of equal parts of stable litter and leaves will be found useful for starting a few early *Gloxinias*, *Caladiums*, *Achimenes*, and roots of *Lilium auratum*; also for cuttings of different kinds; and it will afterwards be useful for the raising of various kinds of seeds. Throw into a heap a mixture of two or three parts of leaves and one of litter, and turn it once or twice, applying some manure-water if dry; the material may also be used for another bed in February. Besides hot-beds necessary for bringing plants into flower, several are required for vegetable forcing, especially where there are few hot-water-heated structures. In April and the two following months, these beds will be useful for soft-wooded greenhouse plants, such as *Balsams*, *Cockscombs*, some annuals, and various odds and ends. In others, *Cucumbers*, *Chillies*, &c., may be grown; and those not required can be removed and used as manure, or turned for forming a compost for the potting bench. Their size must be in proportion to the amount and continuity of

heat they are required to produce. If for starting stove-plants on they may be built as high as 5 feet, but if for growing *Potatoes*, *Carrots*, *Radishes*, and other vegetables, 3 feet will be found sufficient. They sink considerably after being built, and, when the heat begins to fail, the best way of recruiting it is by adding fresh linings around the frames.

Flower Garden.—In warm situations *Violets*, *Daisies*, *Pansies*, *Snowdrops*, *Wallflowers*, *Aubrietias*, and *Primulas* have been tempted to expand, and to these may be added the *Chimonanthus fragrans*, *Jasminum nudiflorum*, *Christmas Roses*, *Cydonia japonica*, *Arbutus*, *Winter Aconites*, *Berberis Darwinii* and *Aquifolium*, *Arabis*, and a few other miscellaneous plants. As a rule, however, flower-gardens are not over attractive at this time of the year; therefore the lawns should be kept clean and well rolled, the walks swept, and the shrubbery borders and similar surroundings attended to, especially as regards the removal of withered leaves. Prune, train, and tie up all plants growing against walls and pillars. If bulbous plants are so far forward as to be injured by frost, should it come, top-dress the beds with leaves, ashes, cocoa-nut fibre, or other material of that kind. Transplant trees and shrubs, repair and make walks, renovate rockeries, if necessary, re-lay turf, and energetically proceed with all operations that tend to forward spring work. Where flower-beds have to be altered in pattern, attention should be paid to them in that respect at once. *Ivies*, *Periwinkles*, and *St. John's Wort* may now be transplanted in shady borders and under trees. Keep the crowns of *Funkias*, *Cannas*, and *Dahlias* in the ground protected with leaves or litter, and examine occasionally such as are indoors, picking out all decaying portions, and rubbing over the incisions with powdered charcoal.

A NEW LAWN-MOWER.

UNDER the title of the "Royal Guinea Lawn-mower," Messrs. Green, of Leeds, have brought out a new lawn

New Lawn-Mower.

mower, of the appearance of which the annexed illustration gives a good idea. It is stated by Messrs. Green to possess the following advantages. 1. It consists of a smaller number of parts than any other lawn-mower; the frame-work is cast all in one piece, and, therefore, is not liable to be twisted, or by any means to get out of order. 2. The cutters are set in the cylinder, without wedging or wiring; and yet they are so firmly fixed that they cannot be shaken, or in any way become loose. 3. The fixings or caps of the cylinder are fitted together by two bolts and two screws only, and the cylinder itself can be adjusted or removed by the most inexperienced person in two or three minutes. 4. The motive-power is given by the travelling wheels, into which a pinion, fixed on the end of the cylinder shaft, is geared, giving revolving motion to the cutters; and it will cut either short, long, wet, or dry Grass, Peat, &c. 5. The Grass-box is fixed behind the cutters, so that the machine will cut Grass close up to trees, seats, walls, and underneath shrubs, without the box having to be removed. 6. It is eminently adapted for banks, slopes, flats, &c. 7. The handle of the machine will suit the height of the person using it at any angle. 8. From the fact that the royal guinea lawn-mower is of such simple construction, the manufacturers are enabled to offer it to the public at a price within the reach of everybody requiring a lawn-mower.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

WINTER AND SPRING CUCUMBER GROWING.

THE accompanying section represents one of the best forms of house for growing Cucumbers or Melons during the winter and spring. It is 7 feet wide, 10 feet high at the back, and 4 feet at the front. A house of these dimensions gives an ample roof area, or training surface, for either Cucumbers or Melons. Three rows of pipes are shown in the plan, and this quantity, though it may appear large, will not be found too much in severe winters, for it takes a large amount of heating surface to keep up high temperatures at such times, without making the pipes hotter than they ought to be. Each row of pipes should be furnished with a stop valve, and in mild weather the front row may be turned off, as, being nearest to the plants, it is more likely to cause injury than the others, should the pipes get too hot at any time. The ventilation is effected as shown at A and B in the plan. The early Cucumber

Section of Cucumber-house.

and Melon-house here is built on the above plan, and is about 35 feet long. From this house we cut a large quantity of Melons in summer, and Cucumbers in winter. Indeed, I would not desire a better structure for such purposes.

Culture of Winter and Spring Cucumbers.

Though the house is used chiefly for early crops of Melons, the successive crops being grown in frames, still we keep the early plants going on all the summer, getting supplementary second and third crops of them; but by the middle of August, or the beginning of September, we get one division cleared and sow Cucumbers—perhaps a dozen good seeds, in a 6-inch pot, of Wilson's Prolific, the old Syon House, or others of that class. Long or large Cucumbers are very good for exhibition, but, for supplying an establishment, short fruits, which are produced in quantity, are in every way the best. Economy is an important object with winter crops, and I have long since discovered that moderate-sized Cucumbers go furthest in the pantry. The seed-pot is plunged in a bottom-heat of 75°; a higher temperature is not necessary, and an atmospheric temperature of 70° by night, and from 75° to 85° by day, according to the weather, is given from the time the plants are sown, till they are thrown out, when they are done. Sometimes, when our boilers are hard pushed, these figures cannot always be sustained, but we do not like to see the top-heat below 65°, even in the coldest nights, at least, not many nights in succession; nor the bottom-heat

below 70°. At the same time the above temperatures should not be exceeded; 85° top-heat should only be allowed on fine sunny days, rather than admit heavy draughts of cold air, but 80° is a good growing temperature, and our winter Cucumbers seldom experience a higher temperature all the winter, and for days together the thermometer is often not above 75°, while the bottom-heat generally ranges between 70° and 75°. I am quite certain that a lower or a higher bottom-heat than this is not attended with any good results. I am describing my own practice exactly, at least, as our Cucumbers have been growing and bearing freely all the winter, and I expect they will go on doing so till May or June. After the seedlings have made their rough leaves, they are potted off into 4-inch pots, burying the stems up to the leaves, and are watered thoroughly with tepid water and restored to their former quarters. While they are getting established in the pots, the bed is prepared for planting in the following manner. Bottom-heat being furnished from pipes, which are only covered with flags, as shown in the plan, a good thick sod is laid in the bottom of the bed (grassy side downward) and above this the soil, about 9 inches or 1 foot deep, which is about the depth of the pit. I am not fastidious about soil, seldom using anything but the refuse of the potting-bench, and such like, as Cucumbers will thrive well in any light rich soil if they get proper attention otherwise. Those who can afford the best materials should use light turfy loam chopped fine and mixed with leaf-mould or decayed hot-bed manure in equal quantities. No better compost than this could be employed. When the bed is ready and warmed to the proper temperature, and before the plants get pot-bound, they are turned carefully out of the pots and planted, 2 feet apart, along the centre of the bed and watered. The after treatment consists in carrying the leaders forward up the wires until the plants are about 3 feet high, when they are stopped. This causes them to send out side-shoots all along the stem, which are also stopped at the second or third joint. These shoots always show fruit, but only one or two are left on each plant at first, and more as the plants get older and stronger. The stopping of the shoots is continued at every second or third joint from the last pinch, and they are also thinned out freely when needful. Crowding of the wood and foliage should always be avoided. The object of planting 2 feet apart at first is only to secure a good crop of Cucumbers early by taking one or two fruits off each plant as soon as possible, but this space is too little ultimately for each plant, and, when it becomes necessary, every alternate plant is removed to give the others more room. Watering must be attended to regularly. The bed should be kept nice and moist, and, when water is given, it should be a thorough soaking till it runs out at the bottom of the bed. Syringing morning and afternoon must also be attended to, and air, more or less, should always be admitted, according to the weather. The roots should also be top-dressed every two or three weeks with a little fresh soil. If these simple directions are carried out, a supply of Cucumbers during winter and spring will not be found a difficult matter. The Cucumber is an easy plant to grow; unlike the Melon, the fruit is not wanted ripe, but only when half swelled, and the secret of the matter is, to keep the plants in a continually growing state.

Diseases.

Mildew not unfrequently attacks the Cucumber, but, when it does, it is generally the result of insufficient ventilation, and too low a temperature. When it does appear, dusting thinly, but evenly, with flowers of sulphur through a piece of muslin cloth is the only cure. Thrips are the most terrible of the insect enemies which attack the Cucumber. For these and also for greenfly, which is sometimes troublesome on the young growths, smoking with tobacco is usually resorted to; but the foliage of the Cucumber is so tender, especially when forced, that smoking, unless done very carefully, is a cure which is often worse than the disease, and one which I never use myself. For these pests, and also for red spider, I apply the "Antidote for Red Spider, Thrips, and Greenfly," by putting a little in the water with which the plants are syringed; and our Cucumbers, which have been subjected to an autumn and winter's hard firing, are at present as green in the foliage as when first planted.

J. SIMPSON.

Wortley.

NOTES OF THE WEEK.

— WE understand that the works at Alexandra Park are progressing rapidly, and that the Palace will be opened early in June. The horticultural attractions will be even greater than before the fire took place.

— THE varieties of *Amaryllis* raised from *A. pardina* are likely to form the most useful race of all. They flower very freely, which is not the case with the older and better known forms; and, better still, they flower freely in winter and early spring. There are a good many of them now in flower at Messrs. Henderson's, Wellington Nurseries.

— WE learn that the following hardy plants are now in flower in the open air in Messrs. Backhouse's nursery at York:—*Crocus Sieberi*, *C. Aucheri*, *C. Imperati*, *Muscari pallens* (syn. *botryoides*), *Cyclamen Coum vernum*, *C. Atkinsii*, *Galanthus plicatus*, *Hepatica angulosa*, and its white variety.

— A NEW work by Mr. F. W. Burbidge on "Cool Orchids and How to Grow Them," is announced by Mr. Hardwicke, Piccadilly. It is illustrated by coloured plates and wood engravings, contains plain cultural directions, and is furnished with a copious list, in the shape of an index, of what are termed cool Orchids.

— IT is not only the late kinds of Grapes that may be preserved by inserting the shoots in bottles of water, as we have so often described and advocated. The season of choice early Grapes may be much prolonged in the same manner. Mr. Bennett has now a collection of Grapes preserved in this way at Hatfield, and among them Sweetwater, slightly shrivelled now, but, in the opinion of many, improved, instead of deteriorated, in flavour. This is a noteworthy fact.

— THE Cockatoo flower of Madagascar, *Angraecum Ellisii*, is now showing a strong spike, in the collection of Mr. John Day, of Tottenham. We believe there are only two specimens of this beautiful Orchid in this country. The flowers are pure white, and sweetly scented, being borne on a spike 18 inches long. It has tails 6 inches in length, and the flowers, when seen sideways, resembles an Australian parrot, whence its popular name.

— IT is said that Grape clusters can be preserved until Easter, as fresh and palatable as when cut, by gathering them in small quantities on clear dry days, removing any decayed berries, fuming them with benzine, and laying them (not in contact, however) between Maize-leaves, in drawers or trays, carefully closed against air and dust. This is an Italian method of preserving Grapes.

— THE fruiterers' shops in Covent Garden and other parts of London are now well supplied with white Almerian Grapes in fine condition. As regards quality, these cannot be compared with fruits of home growth, but they afford a treat to many who otherwise would never have an opportunity of tasting Grapes of any kind. These, and the red Grapes from Lisbon, are imported in boxes and barrels firmly packed in cork-dust, a light, dry, and spongy material well suited for the purpose.

— WE have received, from M. H. Ortgies, the programme of the International Horticultural Exhibition, which will be held at Bremen from the 13th to the 21st of next June. The subjects for exhibition are classed as follows:—Hardy plants; carpet-beds; groups of flowering plants, ornamental arrangements, and cool-house plants; hot-house plants; cut flowers, bouquets, &c.; fruit-trees; Grapes, fresh fruit, and vegetables; preserved fruit, wines, machines, and implements. These are sub-divided into 139 sections, for each of which will be given a silver medal and prizes in money to the total amount of 9,580 marks (about £480). Special prizes of gold medals, silver cups, &c., will also be given by the Emperor, the Empress, and several of the German nobility. Intending exhibitors are requested to write to the office of the International Horticultural Exhibition, at Bremen.

— AT a recent meeting of the Metropolitan Board of Works, the chairman announced that he had received a letter from the solicitors of Mr. Albert Grant, enclosing one from that gentleman offering Leicester Square to the board, and through it to the public, as a free gift. Mr. Grant stated that Mr. Gibson had prepared plans for laying out the grounds. A fountain would be placed in the centre, the square would be railed in, and seats provided for 200 persons. At the four corners it was intended to place pedestals, on which would be set busts of Hogarth, Sir Joshua Reynolds, Dr. Johnson, and Sir Isaac Newton—all celebrated persons, whose history was identified with that of the square. Our only regret is that it is part of Mr. Grant's plan to place a fountain in the square, as a fountain, or any other object in the centre of such a piece of ground is sure to destroy any happy effects the designer may otherwise produce. The centre should be an open carpet of turf, like that of the prettiest squares in Paris. Besides the bad effect of placing such an object in the centre, a dripping

fountain in a small square in this dripping climate is a decided mistake. In a sun-burnt region the refreshing splash of water is more agreeable; but we have always noticed that, in the very hottest as well as coldest countries, the best effect in a square is obtained by having an open centre of turf.

— WE are informed that Alfred de Rothschild, Esq., has kindly consented to preside at the thirty-first anniversary festival of the Gardeners' Royal Benevolent Institution, to be held in the ensuing summer.

— GROWERS of winter flowers will now find a brilliant collection of Cyclamens and Chinese Primroses in the Wellington Nurseries, St. John's Wood. Both families are in charming variety, and both show considerable improvement in the way of novelties.

— WE observe that in this month's number of the *Bulletin d'Arboriculture*, the Hon. Marshall P. Wilder appears to be known on the Continent as *Le Maréchal P. Wilder*. He will, no doubt, be much flattered by the imputation of such high military rank.

— THE prettiest *Amaryllis* we remember to have seen is a new species now in flower in Mr. Wm. Bull's nursery at Chelsea. The divisions of the flower are pure white with two distinct carmine stripes in each. It is a most striking flower, is as yet unnamed, and comes from Peru.

— WE learn, from Mr. Anthony Waterer, that the Planes now being planted in Sackville Street, Dublin, are of the Western variety (*Platanus occidentalis*), supplied from the nurseries at Knap Hill. The important task of superintending the planting has been entrusted to Mr. Moore, the editor of the *Gardener's Record*.

— WE understand that there is a project on foot for the construction of an aquarium, winter-garden, Ferneries, and a recreation promenade, upon a large scale, at Margate. The work will be carried out by a limited liability company, the capital being £15,000; and it is expected that, in all probability, it will be commenced early in the spring. The aquarium itself is to be 250 feet by 100 feet.

— WE have just received from Herr Max Leichtlin a neatly printed list of select plants and shrubs now growing in his garden at Baden-Baden. Among them we notice *Galanthus Imperati*, *Tulipa Greigi*, *Dianthus alpinus flore pleno*, a climbing species of *Linaria*, and many other rare and fine plants. Herr Max Leichtlin's collection of Lilies is, perhaps, the finest in the world, his list containing no fewer than 106 species and varieties of these plants.

— WE understand that a meeting of gardeners is to be held at 11, Eden Quay, Dublin, on Tuesday next, for the purpose of appointing a board of directors and a secretary for a new society, which is to be called "The Gardeners' Provident and Benevolent Society of Ireland," and is intended, by the subscriptions of its members and the donations of patrons of horticulture, to provide a fund for the support of gardeners in old age, in time of sickness, and when out of employment, and, in the event of death, to defray funeral expenses. There is also to be a loan fund attached to the society.

— THE great improvement admirably begun in Leicester Square, the most neglected spot in London, will, we hope, together with Mr. Albert Grant's example, tend to spread. Lincoln's-inn-Fields is a scandal in another way. The huge houses all round have become offices, and the small park which fills the centre of the vast square is almost a voiceless solitude. Surrounding it is one of the densest populations in the metropolis, and crowds of children play on the pavements and the stones, only casting longing eyes at the few children who, with their nursemaids, are occasionally to be seen taking the air on the green sward under the trees. No residential damage would accrue to the offices all round this vast area if it were thrown open to the public. A large and handsome play-ground might be made there without injury to any one, and with the greatest possible advantage to the hundreds of thousands of people who throng the close streets of central London, in the very midst of which this splendid breathing-place has been so long kept shut up.

— THERE were, in 1873, 246,000 allotments of land in Great Britain, of which 242,000 were in England, 1,700 in Wales, and 2,100 in Scotland. The practice of letting land in small allotments detached from cottages is not so common in Wales and Scotland as in England; and, even in England, allotments are comparatively few in the northern districts. The total extent of land let in garden allotments in Great Britain in 1873 was 59,631 acres, which shows almost exactly an average of one-quarter of an acre for each allotment; and the average for England is the same. The average size of allotments varies, however, in the different English counties. In twenty-four counties, in which there were altogether 122,000 allotments, the average size may be said to vary from one-eighth to one-quarter of an acre. In eighteen counties, in which there were altogether 120,000 allotments, the average size may be said to vary from one-quarter to one-half of an acre. One-eighth of an acre is the quantity of land usually considered as much as can be thoroughly cultivated by an employed labourer in his spare time.

THE GARDEN IN THE HOUSE.

MANTEL-PIECE DECORATION.

THIS forms a very important arrangement in the decoration of the sitting-room, and one to which good attention should be given, as the vases on the mantel-shelf occupy a very prominent position, and, unless they form a good example of floral dressing, are better dispensed with altogether. Specimen glasses, with Everlastings, Rose-buds, Pelargonium blooms, or some other flowers, are seen on every chimney-piece, and, as a matter of course, seem invariably to have a one-sided arrangement, which faces towards the room, all that is reflected in the mirror being the back of the flower or leaf, in place of as good an arrangement as that exhibited in front, and which should be the case. The style of decoration which I shall now explain is for each end of the mantel-piece. The first thing to obtain is the stands in which the flowers are to be arranged, and these may be had of various shapes, but those best suited for this purpose are a pair of common zinc troughs, each about 10 or 12 inches long by 5 inches wide, and $3\frac{1}{2}$ inches deep; painted green on the outside and white in the inside. When about to be filled with flowers, they should be filled with sand to within half an inch of the top;

the sand should be then damped, and planted over with common *Selaginella*. If too much water be put on the sand, the flower-stems will not remain firm or upright. It is a good plan to have two pairs of these zinc troughs—one pair in use in the drawing-room, and the other pair, with the *Selaginella* growing in them, in the greenhouse. By this means, as soon as the flowers in the pair in use have faded, that pair of troughs may be removed to the greenhouse, and the other pair introduced therefrom into the drawing-room, and arranged with fresh flowers. The care in the greenhouse will have quite revived the *Selaginella* in the first pair, which will again be quite fresh, and ready to

take the place of the other pair when required, and so on. This will be found a good plan for many other kinds of floral decorations, as well as the above, where zinc troughs or trays are employed. Round the edges of the troughs, Fern-fronds should be used and arranged so as to droop over and hide the sides as much as possible. The best kind of Fern for this purpose is the Lady Fern, such as is sold at the florists' shops, in bundles; and, should the fronds be found too long, they can be cut as short as necessary, and the tip-ends used. After the Ferns have been rightly placed, the flowers should next be arranged, using rather large and bold-looking varieties, such as Roses, Lilies, Clematises, &c. These should be placed so as to stand out well, one from the other, avoiding any tendency to their having a crowded appearance. Branches of Fuchsias look very effective mixed through such flowers as those mentioned, and plenty of foliage must also be placed through them. When the flowers have been arranged according to fancy, the troughs should be placed on the mantel-piece, one at each end, and close to the margin of the ledge; then some long sprays of trailing plants should be inserted in the soil and allowed to droop down at each side. Sprays of *Lapageria rosea*, Clematis, Hops, Passion-flower, Tacsonias, and such like, are admirably suited for this purpose. The different kinds of Ivies, too, claim our atten-

tion for this purpose, being very light and graceful, and obtainable at all seasons of the year—a great point in their favour. Those who do not care for troughs of growing *Selaginella*, can use instead a pair of those pretty small china pots sold at the glass shops for standing on brackets and holding cut flowers. I do not mean those similar to what are sold for dropping pot-plants into, as the latter have always a hole at the bottom for drainage; but the pots I refer to are made on purpose to hold water in which to stand flowers, and in them very effective arrangements can be made, in the same way as that described for the troughs, but they can never be made to look as suitable in shape as in the latter, in which way the accompanying illustration is arranged. At nearly every season of the year we have flowers suitable for this style of decoration. In spring, we have Hyacinths, Tulips, Forget-me-nots, Snowdrops, Scillas, Lily of the Valley, Lilacs, &c. In summer, Roses, Pelargoniums, Fuchsias, Water Lilies, and Clematis. In autumn, Japanese Lilies, Roses, Lapagerias, and *Pancratium fragrans*. And, in winter, in the market, those who have no glass-houses of their own, can obtain Cape Heaths, Chrysanthemums, Arums, Poinsettias, and such like. All the above-mentioned flowers are well adapted for this style of decoration. Specimen-glasses with a few flowers and Ferns look very well on the mantel-piece if dressed all round, but

not to one face. A hand holding a vase in china is a pretty device for a few choice flowers, such as Orchids and Gloxinias; and, as a rule, richly-coloured flowers are best suited for opaque vases, their deep tints being shown to much better advantage on that kind of surface than on any other. A. HASSARD.

Upper Norwood.

Watering Window Flowers.—Most people are fond of growing a few flowers at their windows; but almost every one is puzzled as to the number of times they should be watered in a day. Suppose one purchases a few flowers—say scarlet Tom Thumb Geraniums, Petunias, Heliotropes, Fuchsias, and similar plants, one naturally inquires how often they should

be watered. The answer to this question will be “do not water them till they are dry,” or “till they require it.” The plants are sent home, placed in the window, or wherever they are intended to stand; and, although the drooping points of their branches soon indicate aridity at the roots, the balls of earth are not considered quite dry; therefore, amidst considerable alarm, there is some hope entertained that the safety of the plants will be best ensured by a scrupulous adherence to the directions. Another day is allowed to pass, and the soil at last is as dry as a crust. “Now,” soliloquizes the anxious cultivator, “I surely may water them.” The pots are accordingly charged with water, which the dryness of the soil does not permit to percolate till after some considerable time. The shoots do not regain their firmness, the leaves turn no fresher, and everything testifies, in the most unmistakable manner, that the remedial measure has been withheld till it is “too late.” Undoubtedly it is wrong to keep such plants as those mentioned continually soaking in water by means of saucers, but the soil in which plants grow should never be allowed to get quite dry. The safest condition for such plants is that of moisture, though in winter they require less water than in summer. Ferns, even the deciduous species, I keep moist. Such treatment I have found to ensure success, and if we look at the kinds we have growing in our own country, we find they are moister at the root in winter than in summer. Though the soil in which Ferns are grown, however, should always be kept damp, great attention should be paid to the state of the drainage—K.

GARDEN DESTROYERS.

SCALE ON PLANTS.

THE different species of scale insects that are to be contended with, in both in and out-door gardening, entail a serious amount of labour to keep them down, more especially the brown and white species that infest hot and green-houses. The brown species increases the fastest; but is much easier to kill than the white, which more commonly infests the greenhouse, or plants that are grown in a similar temperature. Brown scale is an insect that will live on many soft-wooded and a still greater number of hard-wooded plants. Even a poisonous family, such as the Euphorbiaceæ, are subject to them; but, on plants of this description, they do not increase so fast, and are so much smaller that they might be easily mistaken for a different species. In the stove, they require unremitting attention to keep them from doing serious mischief. Crotons and Allamandas are the only plants here which I have found exempt from their attacks. Ixoras, Dipladenias, Francisceas, Combretums, Rondeletias, Stephanotis, Euphorbias, Gardenias, Tabernæmontanas, and plants of similar description, possessing foliage sufficiently hard to withstand dressing with Stevenson's "Abyssinian Mixture," or Fowler's "Insecticide," at 4 oz. or 5 oz. to the gallon, should be washed with one or other of these mixtures as often as they require it—laying the plants down on their side over the trough. In the case of small plants, the use of sponge and brush may suffice; but, when the plants get large, it takes too much time to clear them in this way. These washings should be repeated as often as required, not allowing them to remain undisturbed until the plants are swarming with them, as is sometimes done; but it is in the autumn and winter, when the plants are at rest, that an effort should be made to get the insects destroyed as much as possible. Such plants as *Clerodendron Balfourianum* and *Bougainvilleas*, that when in full leaf and active growth will not bear the application of the mixture sufficiently strong to kill the insects, should receive two or three dressings whilst at rest during the winter: and any plants that are cut down, as *Clerodendron Kämpferi* or *C. fallax* generally are in the winter, should, before they break, receive a dressing of the insecticide, at 6 oz. to the gallon. With Palms, and other large-foliage plants that are attacked by these insects, the safest method is sponging the leaves with clean water, as an application of the insecticide sufficiently strong to kill the insects is almost certain to disfigure the foliage. The insect will live upon Pines, but is comparatively small on these plants, and does not increase so fast, neither does it get so far down into the heart of the plant or into the base of the leaves, as white scale, and it can be kept down by the use of the sponge. Most thin-leaved Orchids, such as *Lycaste Skinneri*, *Phajus*, *Peristerias*, *Houlletias*, *Anguloas*, &c., are subject to brown scale. From these they must be carefully removed with the sponge. On *Vandas*, *Saccolabiums*, and *Aërides*, they do serious harm if left undisturbed, although on these plants they do not get larger than the mussel scale on Apple or Pear trees; on these Orchids they occupy both the upper and under surface of the leaves, quickly turning them yellow, after which they are certain to fall off prematurely, seriously weakening and disfiguring the plants. Exotic Ferns are much infested by them. When the plants are quite at rest, some of the harder-fronded kinds may be washed with Abyssinian mixture; tender-leaved kinds, such as the *Adiantums*, must be cleaned with the sponge; also *Gleichenias*, which are very difficult to keep clean if once they get affected with these insects. Heaths, as well as most hard-wooded greenhouse plants, are subject to them, although here they do not increase so fast; yet, if left undisturbed, they do serious harm by clogging up the pores of the leaves by the sticky excrement they cover them with, to which all the dust which comes in contact adheres, causing the leaves to turn yellow and fall off. With small-leaved plants of this description little can be done with sponge or brush. Washing with Fowler's insecticide at 5 oz. to the gallon in water, when the plants are at rest, is the only remedy I have found effectual; it also removes the dirt from the shoots and leaves. With soft-wooded plants the best remedy is the use of sponge and soft brush, with clean water, as the plant will not bear the use of any insecticide strong enough to kill the insects. *Crinums*,

Vallotas, and *Amaryllis*, affected with it must also be treated with the sponge. With *Camellias*, the insect is mostly on the leaves; these plants will bear washing with the insecticide, 5 oz. to the gallon, as soon as they have done flowering, before they begin to grow; but it is dangerous to use the mixture when the buds are at all prominent, as it frequently causes them to drop. In the case of these and other pot plants, a good deal may be done in the way of preventing the spread of the different species of scale by careful isolation. If plants that are quite free from the insects are never allowed to touch or stand under any that are affected, they will not be attacked. The females being wingless, they cannot get from one plant to another unless the plants touch each other. A frequent source from which the different species of scale spread, is from roof climbers, that are infested, dropping them upon any plants placed under them. Where plants on the roofs of conservatories and other houses are infested with these insects they should either be removed altogether, or taken down, cut back into the hard-wood, and thoroughly immersed in the washing-trough containing a sufficient quantity of the insecticide (6 oz. to the gallon) to cover the head of the plant, in which it may left for an hour; for brown scale, one dressing in this way will generally be found sufficient. Peaches, both under glass and on the open walls, are sometimes infested with brown scale. As soon as the leaves are off, go over every branch with a brush, and remove the insects, loosing the trees from the trellis or wall, and give them a thorough dressing with sulphur soot, and clay, made to the consistency of thick paint, to which add 2 oz. of soft-soap to the quart of the above mixture. This should be done as soon as the leaves are off, as, if the flower buds are too prominent before the dressing is applied, they are liable to drop off.

The White Scale.

White scale does not increase so fast as the brown, neither does it infest so many species of plants; but it is much harder to kill, requiring a stronger application of whatever insecticide is used than most plants will bear. It establishes itself more on the old wood, down at the extreme base of the leaves, under the flower-buds, or in any secure crevice in the plant where it is difficult to clean. It is not so often met with in hard-wooded stove plants; and, if a plant here happens to be infested with it, it should be placed so as not to touch any others, and should be repeatedly gone over with a sponge and stout brush, getting into every crevice in the bark right down to the collar as far as the soil, using "Abyssinian mixture," at from 6 to 8 oz. to the gallon, and brushing the mixture well in after removing every scale perceptible. If the plant can be cut back into the hard wood after it has completed its season's growth, all the better, as the old mature wood is more likely to withstand the application of the mixture at this strength. Orchids are very subject to it; on them there is no safe method except the sponge and brush, getting right down to the bottom of the leaves and to the base of the bulbs, for there is no portion of the plant, roots included, that is above the soil, but where the insect will establish itself. If it is allowed to remain undisturbed until it exists in large numbers in the bottom of the leaves of *Aërides*, *Saccolabiums*, *Vandas*, or *Cattleyas*, it turns them yellow, and they will fall off prematurely. Use the brush dry, and with care, so as not to scratch the leaves, or serious injury will be done; finish with the sponge and clean water. When this insect makes its appearance upon an Orchid, the plant requires to be gone over frequently and very carefully at short intervals, or there is not much chance of thoroughly eradicating the pest. Any insecticide that I have ever seen tried, sufficiently strong to destroy these insects, has either killed the plants outright, or seriously injured them. In the Orchid-house, infected plants should never be placed so as to touch such as are clean. I have never known the insect spread except by actual contact with plants affected. It is upon hard-wooded greenhouse plants, conservatory climbers, *Camellias*, and Heaths that they are most difficult to deal with, consequent upon the leaves and flower-buds of few plants being able to withstand the mixture in a strong enough state to kill the insects. Such things as *Acacias*, *Tacsonias*, *Mandevillea suaveolens*, *Bignonias*, *Hardenbergias*, *Lapagerias*, *Rhyncospermum jasminoides*, *Stauntonias*, &c. may be cut back in the spring before any growth

commences, and dipped in "Abyssinian mixture," 8 or 10 oz. to the gallon, used at a temperature of 90°, in which allow them to remain for an hour; repeat the dressing in ten days, or at all events before the buds begin to break, or the mixture at this strength will destroy them; and if their first effort at growth after heading down is killed, it will most likely be death to the plant. Camellias are very subject to this insect; there is only one season of the year that it is safe to dress them with the mixture; that is, just when they have completed their growth and are setting their flower-buds. The mixture is ineffectual at less than 6 or 7 oz. to the gallon, and, if used after the plants have flowered, with their wood buds ready to burst, or afterwards while the leaves are tender, serious injury will follow. Just as the plants are setting their buds I have found the best time, as, if deferred until the buds get large, it will cause many to drop off. Previous to syringing with the mixture the whole of the plants should be gone over carefully with a tooth-brush, and as many of the insects as can be seen removed. In the case of very large plants, that cannot be laid down over the trough whilst being syringed, the best method is to apply the mixture with the brush, loosening all the insects as the work proceeds; allow the mixture to dry on, and give a second application in the course of a fortnight. Where Pines are affected with this insect, it gets down into the axils of the leaves, so far as to be almost out of the reach of anything that will either kill or remove it. The best thing that can be done is to burn all affected plants, for it costs more in labour to exterminate the insect than the plants are worth. There is a small black scale, white round the edge, sometimes met with on Orchids, as well as hard-wooded and other plants. Its habits are similar to those of the white scale, and it is equally difficult to kill, requiring to be dealt with in the same manner.

Scale on Fruit Trees.

Apple and Pear trees are subject to the attacks of mussel scale, which if left unmolested ultimately destroys them. The insect spreads slowly, and not without actual contact. Care should be taken in the selection of young trees that they are free from this insect. I have tried dressing with soft-soap and soot, "Gishurst" 8 oz. to the gallon, and numbers of other mixtures, but never found anything effectual except pure train oil. It is necessary to be careful in procuring this oil, as an article is sold under the name which is injurious to the trees. Train oil is, I believe, produced from the seal. Every portion of the trees must be thoroughly painted over with the oil, getting into every crevice. This should be done as soon as the leaves are off, for, if done late in the winter, the blossom-buds will suffer. I had a collection of some fifty trees dressed with the oil, and it was so far effectual as to not require repeating for a dozen years. The trees were over-vigorous, and the dressing checked their growth to something like what root-pruning would have done. They bore splendidly afterwards. It will at once be seen that a dressing of this description is only possible on trained trees of moderate size; with large orchard trees it would be out of the question, for unless the whole surface of the bark is touched with the oil the results will only be partial. Pears on walls require un-nailing, so as to get thoroughly to the back of the trees, brushing the oil in as for the Apples.

T. BAINES.

BLACKBIRDS AS GARDEN DESTROYERS.

UNLESS your correspondent, "Bad Shot," gets all his surrounding and suffering neighbours to join him in a systematic raid upon the blackbirds around, he will find that no individual effort will lessen their number. They are naturally a solitary bird, and breed by hundreds in the most unfrequented and lonely copses, and hedgerows, after the fruit season, return to their lonely haunts. When fishing in autumn, I have seen them by scores along the margin of reedy and unfrequented streams in this county. If it is any consolation to "Bad Shot" to know that he is not alone in his sufferings, I can assure him that I could "a tale unfold" that would make him thankful that his case is no worse. The protection of fruit from birds, in many places in this neighbourhood, is a thing of absolute necessity. This we can accomplish by a little expense and time; but large squares of autumn Peas are not easily protected, and, where this cannot be done, the crop is entirely eaten up by a little sharp-billed bird of the titmouse species. As soon as the pods are about half-filled, they begin their work of destruction, and never leave them until the Peas are cut

down by frost. The little birds referred to are never seen near gardens here during the summer months; but, like the blackbirds, they appear to be drawn to spots where their favourite food exists by a sort of instinct. There is one thing that experience has taught—namely, to cover all fruit before it is ripe. If blackbirds are prevented at the outset from getting a taste of it, they are not likely to cost the gardener so much trouble as they would otherwise do. They are voracious feeders, and it is not surprising to hear that they cleared your correspondent's Currant bushes in so short a space of time as he names. In autumn here, during severe weather, they often fell upon Apple-trees in, as it were, showers, and devoured great quantities of the fruit. They are, however, less destructive now that we grow our Apples upon dwarf trees. No doubt the cause of their rooting up your correspondent's beds is searching for worms, which are their natural food, and they never get tired in looking after it. Last year a neighbour discovered what was, for a time, an effectual scarecrow to blackbirds—namely, a stake, 7 feet long, stuck into the ground at an angle of about 45°; from a string tied to the end of it there was attached an old hat; the string was passed through the centre of the crown, and by this means the hat appeared above the bushes, as if it were placed upon the head of a person amongst them. Every breath of wind stirred it, and for a time it was effectual in scaring off the birds from the fruit. J. T.

Shawdon, Alnwick.

HAVING suffered from blackbirds last year to a great extent I thinned their numbers in the following way, and I would advise "Bad Shot" (see p. 58) to try my method:—Take some small rat-traps and tie a small piece of Apple or Pear on the plate; the best way of fastening the baits on the plate is to take a large needle and thread and run it through the middle of the piece of Pear, or a Gooseberry, and than tie it round the plate. This prevents the birds from drawing the baits off when pecking at them; a bunch of Currants can be fastened on in the same way, by tying them round the middle of the plate. The traps may be placed on the surface of the ground, under the trees or bushes infested by the birds, and, if they get a little more wary by the beheadings going on, the traps may be sunk a little and covered over with mould. This is the most humane way of destroying blackbirds, for they are invariably caught in the traps by the neck, and killed instantly. In shooting at them, if not killed they are tortured by broken wings or legs, or fly off, with shots in them, to die a lingering death. Last year, in the kitchen-garden here, after all the late Gooseberry and Currant bushes had been netted up, the blackbirds turned their attention to some small standard trees of Doyenné d'Été Pears just ripening. Three of these steel rat-traps were set under one of the bushes baited with small pieces of the Pears, and seven blackbirds were caught in one day, and all by the necks. All through the autumn these traps were used and the blackbirds were considerably thinned, so, as I hope, to keep them under another year. The thrush is another great fruit eater, but it is worthy of its salt, being a great devourer of snails and slugs in the autumn and spring months; it is, likewise, not so daring as the blackbird, and is seldom caught in these steel traps like it. The blackbird will make its raids on all kinds of fruit, even getting under the nets, where a hole can be found, and the ripe Nectarines in the houses are not safe from it, when it finds the lights open.

WILLIAM TILLERY.

Welbeck.

Ants and Fruit Blossoms.—These little pests are often very troublesome and injurious to fruit when ripening in hothouses, and they sometimes do much injury to the blossoms of the earliest Peach and Nectarine trees in hunting for aphides and honey. I have used thick treacle spread on pieces of brown paper to catch them; they get entangled in the mass when sucking it, and their bodies may be swept off the edges at different times till the nest or nests are much thinned of them. They may likewise be poisoned by mixing half-an-ounce of arsenic in some brown sugar, but this is a dangerous remedy, and ought not to be tried unless in locked-up houses. The bodies of little dead birds, if placed in their runs, will entice them to feed on their flesh; when they may be destroyed in myriads by pouring boiling water over them when busy at their feast.—WM. TILLERY, Welbeck.

Earwigs.—These can best be trapped by putting Bean-stalks or small garden-pots, half-filled with Moss, on the top of short stakes. They are nocturnal in their feeding on flowers and fruit, and they retire into these traps in the day-time, when they may be cleared out and destroyed by blowing them into a pan of hot water.—T.

Blackbirds v. Fruit.—In reply to your correspondent, "Bad Shot," I would suggest that, if in the approaching breeding season he could procure a pair of young kites or hawks, and place them in his garden, looking after their wings from time to time, he would drive off the blackbirds, &c. Of course he must feed the kites. A relative of mine tried this plan with great success.—J. L. H. S.

THE FRUIT GARDEN.

GRAFTING FRUIT TREES.

(FRESH CUT *versus* RETARDED SCIONS.)

ABOUT the 22nd of October, 1872, I moved a young Apple tree into the place where I intended it to remain. From a dwarf bush it had been altered into an espalier, and had stood in its old place four years. Its name I know not, but its character resembles that of Cox's Pomona. It was in full leaf when moved to its new quarters, and several weeks elapsed before it shed all its leaves; and, although its removal was not effected without considerable mutilation, or, rather, shortening of the roots, the tree did not appear to suffer, the leaves only turning a little black before they finally fell from it. I took off one of the shoots its entire length, about 2 feet, and stuck it upright in the open ground, at a short distance from the tree; and I watched to see if there would be any difference in the appearance of the two as winter approached. Both, of course, received the same amount of sunshine and cold, and I thought, if the removal was a success, it would be seen in the more healthy state of the foliage on the tree, owing to the supply of nourishment afforded by the roots. The severed shoot, however, appeared to follow the example of its parent, and, by degrees, the leaves disappeared from it in like manner. This shoot remained in the same place till towards the end of March, 1873, when I selected two good Crab stocks; on one I grafted the middle portion of this shoot, on the other, a scion cut from the removed tree. Both scions were of about the same size; both made about the same amount of growth. I could see no difference between that which had been cut off at the time of grafting, and that which had stood up in the open border all the winter. About the same time, I grafted on a Quince stock a shoot taken from a Beurré de l'Assomption. It was given me by a neighbour, and its appearance, at the time I received it, was anything but promising. How long it had been severed from its parent I failed to ascertain, but it has made three shoots, each about a foot long, and, I doubt not, will, in time, make a healthy tree. I have two specimens of the Gratioli of Jersey, one on a Quince, the other on a Pear-stock, the scions of which were taken from the head of a tree grown in France, but which was broken off on its journey to England, and lay for some time apart in the purchaser's garden. My experience, though somewhat limited, extends over a period of more than thirty years, during which time I have never been able to discover any decided advantage in removing the scions many days before they are attached to their stocks, as is generally recommended; indeed, I was once assured by an old jobbing gardener, that he always found the recently severed scion succeed, while others failed, in his hands. Apples and Pears do not seem to be particular with reference to the time of their insertion, but Plums I have found invariably to fail if the operation of grafting is delayed till the buds begin to show colour. Last year, all but one that I had put on failed, owing, probably, to the buds being too forward; whereas, from one long shoot of an Imperial Gage on a former occasion, at an earlier time of the year, I made six portions, rejecting the terminal one, but successfully grafting the others. A matter of more importance, perhaps, than the time for cutting off the scions, and their treatment generally, appears to be the time when the stocks should be headed back. No doubt it is a very safe plan to have this operation performed some weeks before the time for grafting, though here, again, I am unable to trace failure in any instance to having delayed this operation to the moment of joining the scion to the stock. The truth is, Nature is very patient, and not unfrequently interposes to keep alive what the theories of the horticulturists, however correct in principle they may be, would have doomed to destruction. Nevertheless, it would be well for those who intend to graft, to prepare their stocks at once, cutting them back to within an inch, or so, of the place where the grafts are to be inserted. There is no need to tamper with Nature, and it is not unreasonable to suppose that the sudden removal of about nine-tenths of a tree, after the terminal buds have opened, will injuriously affect any scion that, under such circumstances, has been attached to it.

PEACHES IN BLOOM IN JANUARY.

AS SOME of our early Peach trees are now in bloom, perhaps a minute description of the way in which we treat them may be of use to some of your readers. It is as follows:—The temperature of the Peach-houses wherein the trees are now in bloom, we have raised from 50° to 55° at night, and it is not allowed to exceed the latter with fire heat, but throughout the day it is permitted to range from 60° to 65° with sun heat. Air is freely admitted on all favourable occasions, in order that the condensed moisture may evaporate, as a great many failures in setting result from the pollen being wet. Syringing is suspended, until the petals begin to fall off, after which time the operation will be carefully resumed twice a day. Although the trees at this stage are not syringed overhead, the house is never allowed to become dry, else an attack of red spider will be inevitable, and the trees and fruit crop impaired in consequence. The paths and borders are sprinkled with tepid water night and morning, and two or three times during the day, should the sun be sufficiently strong to dry the atmosphere. The pipes, too, are sprinkled in the mornings, as the blossoms are greatly refreshed by the fine dew thereby produced. Assuming that the borders have had a liberal supply of rather weak manure-water when the trees were started into growth, they will not, as a rule, require more heavy watering until the fruit has attained the size of Peas, when a limited quantity of pure water will be applied, and which will suffice until the stoning is completed, after which period manure-water in abundance will be given. When the blossoms have fully expanded, a camel-hair brush is used to disperse the pollen, and thus enable the fruit to set; but, as the flowers are not all open at the same time, the operation is repeated two or three times. Some disbud the fruit-buds while the trees are in blossom, others when the petals have fallen off and the fruit is set, and others when the fruit has stoned, the latter practice being the one we adopt, and consider the most commendable in the case of early forced Peaches. The wood-buds are thinned when sufficiently large, and if the bearing wood has been well ripened, the fruit, too, are thinned a little, if thickly set, when well formed; but when the fruit has stoned, it may be done with more safety. Nothing can be more vexing to a gardener than, after he has finished thinning, to find two-thirds of those left fall off, but as opinions differ so much in the performing of this operation, it is best to study the strength and vigour of the plants, and act accordingly. Green fly sometimes make their appearance in the case of neglected trees, when the wood-buds begin to grow, and they should be checked at first sight with syringing and fumigating, but the latter operation ought to be practised when the trees are dry, and when they are not in bloom. The fumigator we use is a very simple and effective one, and consists of a wire sieve inverted; the tobacco or tobacco-paper, after being chopped and teased, is placed in a little heap on the middle of the sieve, and over it is inverted a 10-inch pot with a chip out of the side at the brim. The hole in the bottom of the pot is enlarged a little to admit a piece of a 2-inch drain tile, which is therein inserted, and acts as a vent, causing a suction or draught. The tobacco-paper being fired, a good volume of smoke is produced, and the fumigator can be readily moved about whilst in use, and fed by lifting off the pot and replacing it again. The man in attendance has always a can of water along with him in order to quench any flame, as the hot dry air therefrom is extremely detrimental to all sorts of plants, and it wastes the fumigating material as well.

JAMES MORRISON.

Wotton Gardens, Aylesbury.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Out-door Grapes.—Would you kindly name the best black and white Grapes for out-door purposes?—J. L. H. S. [Black Hamburgh and Esperione, black; Royal Muscadine and Sweetwater, white.]

Gum in Peaches and Nectarines.—I have been filling up vacant spaces in my Peaches and Nectarines by means of herbaceous approach. Can any of your readers inform me what I should do to get rid of the gum which comes at parts where the grafting was done?—H. S.

Apricots as Standards.—I should be much obliged to any of your readers who would inform me if the Apricot perfects its fruit as a standard tree in any part of England, and if so, where. I have heard of good crops being gathered from a tree in Worcestershire.—J.

Wash for Fruit-tree stems.—This is a good time to remove the green mould from the stems of young fruit-trees by the application of strong brine. I find that those done last year do not require any cleaning this. For small trees an old toothbrush is perhaps the best instrument to use.—B. S.

Vines for a Hamburgh House.—Would some of your correspondents kindly furnish me with the names of the best Vines to plant along with black Hamburghs, say three white and three black sorts? There are now so many sorts from which to select, that one is at a loss what to plant. Would the Duke of Buccleuch do for a Hamburgh House?—G. S. D.

Bottoming for Vine-borders.—Will some of your correspondents say whether slates are good things, or not, to use in the way in which they are put (placed on the roof of a house) to keep decomposing soil from mixing with rubbish in a Vine-border? Faggots I object to, because of Fungus, and turves

THE FLOWER GARDEN.

THE DOUBLE TIGER LILY.

OUR old friend the Tiger Lily is a very showy and valuable plant, but it is surpassed in value by the splendid double form which we this week figure. It is, of course, as hardy and as easily grown as the common Tiger Lily, but, being rarer,

plant grows from 3 to 7 feet high, and its fine double flowers are well shown in the accompanying illustration.

PELARGONIUM TRIAL AT CHISWICK IN 1873.

As in former reports regarding the Pelargoniums grown at Chiswick, we have selected those kinds only to which First-class Certificates

Flower of the Double Tiger Lily.

deserves the best attention we can give it in the way of deep and rich soil. As the good plan of placing Lilies here and there among dwarf masses of Rhododendrons is now happily becoming fashionable, this kind will come in as a valuable aid to those already used for that purpose. It should be in every garden. It is one of the many fine Lilies which Mr. William Bull has introduced, and of which he holds a large stock. The

have been awarded, under the direction of the Floral Committee, or at least marks equivalent to that distinction.

PELARGONIUMS AS BEDDING PLANTS.

Golden-variegated Zonals (Golden Tricolors.)

Of the older sorts, Amy Richards, Louisa Smith, and Macbeth proved to be varieties of first-class merit, and to be the three most distinct of the stronger-growing sorts, whilst Florence was the best

in the dwarf group. The following sorts were tried for the first time as bedders :—

BEAUTIFUL FOR EVER.—Bright shining foliage, with broad very bright red zone, and very little green; a very good variety.

COL. LLOYD LINDSAY.—Leaves, flat, rounded; zone, bright rosy-red, of moderate breadth, with even golden margin; moderately vigorous.

COUNTESS OF ENNISKILLEN.—Leaves, large, in the centre greyish; the zone rosy-red, irregularly vandyked, with broad edge of creamy-yellow; habit, vigorous.

MADONNA.—Leaves, with broad zone of deep bronzy-red, and narrow edge of yellow; bold and good.

ORIENTAL.—Flat foliage, with broad zone of very bright red; a moderate grower, and very effective.

PETER GRIEVE.—Leaves, large, flat, with fiery orange-red zone, and broadish margin of yellow; telling.

PRINCESS LOUISE.—Leaves, large, flat, with a medium edge of yellow, and a broad zone of orange-red; effective.

The above were all contributed by Messrs. E. G. Henderson.

Silver-variegated Zonals (Silver Tricolors).

CIRCASSIAN BEAUTY (Hodgson).—Leaves, small, with very bright pink zone; free and good; covers tolerably well, being of close growth.

FAIR ROSAMOND (E. G. Henderson).—Leaves, well developed and of good colour.

LASS O' GOWRIE (E. G. Henderson).—Leaves of medium size, rather crumpled, with very broad and bright zone, and creamy-white edge; very effective.

Silver-margined.

Among the older sorts, Albion's Cliffs was considered the best amongst the larger and stronger-growing varieties; and Flower of Spring the best of the dwarf, compact-growing, creamy-edged sorts. Miss Kingsbury and Silver Chain were also noted as varieties of the first order, the former with cerise-scarlet, and the latter with rosy-tinted flowers. The following were grown for the first time :—

GOLDEN BRILLIANTISSIMA (H. Park).—A form of the old Brilliant, of compact growth, with the leaves irregularly edged with yellow and creamy-white; flowers, very freely produced, of a brilliant orange scarlet; remarkable for its mixed gold and silver variegation.

LAURA (Bland).—In the way of Albion's Cliffs, but more erect; strong grower and rather coarse; leaves with brownish-red zone and cream-coloured margin; bears large trusses of pale scarlet flowers.

In this group, White Lady and Waltham Bride, both dwarf sorts, were retained for their white flowers; while the following were discarded :—Alma, Brilliant, Maître d'Hotel, Mrs. Lennox, Mountain of Snow, Pearl, Princess Alexandra, Snowflake, Variegated Stella.

Golden-leaved.

In this section, the committee decided that both Creed's Seedling and Crystal Palace Gem retained the high character they had already received. The former was subsequently noted as the best of the purely golden-leaved sorts. The Crystal Palace Gem is of spreading habit, and its golden-tinted leaves have a central green patch; it is in the way of Cloth of Gold, but smoother.

Bronze Zonals.

A very useful group for bedding purposes, but amongst the varieties of which there is necessarily great similarity. Among the good sorts of older date, the committee specially approved Maréchal MacMahon and Black Douglas, and Rev. C. C. Peach was noted as of strong and rather coarse habit. The novelties included the following :—

GOLDEN HARRY HIEOVER (E. G. Henderson).—Dwarf spreading habit, with small cupped foliage of a bright greenish-yellow, with narrow dark zone; very free and good; flowers, pale scarlet. This is very distinct in habit from the ordinary Bronze Zonals, being much less vigorous, and altogether of smaller growth.

CROWN PRINCE (Acton).—Leaves, even, bright yellow, with broad bright dark brown zone; small pale scarlet flowers; a favourite with the market florists; habit, neat.

EMPEROR OF BRAZIL (Downie & Co.)—Free grower, of compact habit; leaves, greenish-yellow, with broad dark brown zone and narrow margin; the leaves are inclined to cup.

FREELIGHT (Carter & Co.)—Leaves of moderate size, even, clear yellow, with very broad bright reddish zone, and narrow even edge; habit, very compact; flowers, salmon-colour. A really first-class variety.

MRS. ELLIOTT (Downie & Co.)—Leaves, yellow, with bright bronzy zone.

REINE VICTORIA (E. G. Henderson).—Leaves, large, flat, bright yellow, edge of medium width, and broad bright red-brown zone; the marking bold and effective.

Pink-flowered.

Several new varieties of this section were tried, of which the following were approved :—

AMARANTH (Pearson).—Free habit; leaves, green; flowers, deep

rosy-pink, almost magenta, medium-sized; large trusses on very long stalks.

BELLA (Carter).—Leaves, green; flowers, bright rose-pink, with white blotch on upper petals; very pleasing and effective.

CLEOPATRA (Barrett).—Free spreading habit, and free-flowering; leaves, green; flowers, bright rose pink, self-coloured, on long stalks, abundant.

EVANS'S SEEDLING (Evans).—Dwarf compact habit, with zoned leaves; in the way of Welbeck Nosegay, but of closer and smaller growth; flowers, bright rose-pink, with white blotch on upper petals; very free bloomer, and very bright-looking.

MRS. HALIBURTON (Bland).—Growth, free but compact; leaves, green; flowers, rose-pink, self-coloured; in the way of Christine, but an improvement on that fine old sort.

WELBECK NOSEGAY (Tillery).—Compact free-growing habit; leaves, dark-zoned, slightly cupped; flowers, abundant, large, bright, deep rosy-pink, with white blotch on the upper petals; good.

Scarlet and cerise-flowered, &c.

The following varieties were selected for approbation, namely :—

BEGERE (Downie & Co.).—Habit, vigorous; leaves, with broad and moderately-dark zone; flowers, bright scarlet, in very large trusses; one of the nosegay race.

CHUNDER SEN (E. G. Henderson).—Habit, vigorous; leaves, lobed, with narrow vandyked zone; flowers, very bright orange-scarlet, fine.

DR. LIVINGSTONE (Carter).—Of moderately vigorous habit; leaves, flat, broad, with a medium zone; flowers, very bright scarlet, large, and of fine quality.

DON GIOVANNI (W. Paul).—Of free habit; leaves, with broad, darkish zone; flowers, scarlet with white eye, of fine form and high quality.

FOREST HILL NOSEGAY (Downie & Co.)—A most exquisite variety, of free, dwarfish, compact habit, with the leaves lobed and faintly zonate; flowers, abundant, in large trusses, rosy-salmon, paler down the centre of the petals.

Of other sorts which were considered as meritorious, the following deserve to be particularly mentioned :—Warrior, Punch, Excellent, Vesuvius, Jean Sisley, Lucius, Bayard, Soleil, and Waltham Seedling, all well-known varieties, were regarded as standard sorts of their respective colours and habits.

Marbled-leaved Zonals (Fancy Zonals).

This group, distinguished by the marbled-green of its leaf-blades, and the pale stripings of its stems and flower-stalks, has received an addition of some merit, namely :—

KATE CREED (Creed).—A free-blooming variety of good quality, the leaves marked, in addition to the marbling, with a very dark zone varied in hue, and the flowers being of a light reddish-scarlet.

Ivy-leaved.

About a dozen varieties of this group were bedded out with but partial success. *Peltatum elegans* was very pretty, with deep rosy-lilac flowers of good form. Duke of Edinburgh and Ariosto were the same, or indistinguishable. Argus was of vigorous habit, and had dark-zoned leaves and rose-coloured flowers. Dolly Varden had golden-green leaves, marked with a bronzy zone.

PELARGONIUMS FOR POT CULTURE.

It having been found, after several years' experience, that the Pelargoniums of the salmon-coloured class especially, were not adapted for bedding purposes, while they were known to be exceedingly ornamental as pot plants, the Floral Committee decided last year not to grow them and the allied kinds again in the open beds, but to institute a trial under glass. This was accordingly done, and, with the results indicated below, the whites and the ocellate varieties—those, that is, with pale colours spotted near the centre or eye—being also included in the trial.

Marks of merit were awarded to but one variety, which proved still more beautiful as a pot plant than it had as a bedder, namely :—

FOREST HILL NOSEGAY (Downie & Co.)—Remarkably free in growth, without the least coarseness; leaves, lobed and slightly zonate; flowers, very freely produced in large trusses, of a bright orange-tinted salmon shading off, the centre of the petals being paler, with a bluish flush; very handsome.

The following annotated sorts were selected as the best of the different shades of colour, the notes being made from the plants as grown under glass.

Salmon-coloured and ocellate sorts.

BELLE ESQUIMOISE (Fraser).—Very large flowers of fine shape; white, with pink centre; extra good.

DR. NEWHAM (E. G. Henderson).—One of the marbled or fancy

set; habit, spreading; leaves, with pale centre; flowers, abundant, in neat trusses, of good shape, rosy-salmon; good.

EMILY LICAU (Bull).—Leaves, with dark zone; flowers, in compact trusses, neat, deep orange-tinted salmon; good.

EUGENE MEZARD (Veitch).—Leaves, zoned; flowers, in compact moderate-sized trusses, salmon-pink with white eye; good.

GLOIRE DE CORBENY (Fraser).—Leaves, with dark zone; flowers, in long-stalked trusses, bright deep orange-salmon, pale at the edge.

HOGARTH (Bull).—Leaves, zoned; flowers, in close trusses, of a deep orange-salmon colour; good.

HORTENSIA (Fraser).—Leaves, zonate; flowers, very freely produced, in large trusses, delicate pink, with paler centre, not unlike a *Hydrangea* in appearance; good.

LA FONTAINE (Low).—Leaves, zonate; flowers, free, in neat trusses, deep salmon-orange; good.

LE PROPHETE (Fraser).—Of dwarfish habit; the leaves zoned; flowers pink with deep salmon eye; good.

MADAME VAN HOUTTE (F. & A. Smith).—Leaves, zonate; flowers, veiny bluish, with a conspicuous ring of scarlet around the eye; good.

MONS. C. ROUILLARD (E. G. Henderson).—Leaves, zonate; flowers, flat, in neat trusses, finely-shaped, deep salmon with deeper eye.

PRESIDENT THIERS (E. G. Henderson).—Leaves, zonate; flowers, large, in neat trusses, deep orange-salmon; good.

PRINCESS ALICE (Downie & Co.).—Of dwarf neat habit; the leaves zoned; flowers, white with bright scarlet eye; good.

POLLY KING (G. Smith).—Leaves, zonate; flowers, large, in large compact trusses, salmon-pink with white eye.

QUEEN OF BEAUTIES (F. & A. Smith).—Leaves, darkly zonate; flowers large, in large close trusses, bluish with deep salmon centre.

REMUS (W. Paul).—Of neat habit, the leaves zonate; flowers, in fine compact trusses, of excellent shape, white with salmon eye; very good.

RENOWN (Bull).—Leaves, darkly zonate; flowers, in good compact trusses, deep orange-salmon; good, better shaped than Emily Licau.

WILHELMINA WEICK (W. Paul).—Leaves, zonate; flowers, large, in large bold trusses; bluish with pink centre; good.

White-flowered.

MISS COLLINGWOOD (Pearson).—One of the marble-leaved or fancy group, and very effective; leaves, zonate; flowers, large, of good form, bluish-white, growing in neat trusses.

PURITY (Bull).—Leaves, zonate; flowers, large, pure white; good.

THE BRIDE (Veitch).—Leaves, zonate; flowers, large and freely produced, of a faint bluish-white; good.

VIRGO MARIA (Fraser).—Leaves, zonate; flowers, white; tall-growing.

WHITE CLIPPER (Fraser).—Leaves, zonate, bright green, with faint zone; flowers, large, in good trusses, in the way of Virgo Maria, but of better shape, the lower petals being less open; good.

WHITE PRINCESS (E. G. Henderson).—Of dwarf habit, with the leaves zonate; flowers, in neat compact trusses, pure white.

WHITE SWAN (Downie & Co.).—Leaves, zonate; flowers, of good form, on long-stalked trusses, pure white.—*Royal Horticultural Society's Proceedings.*

RAISING BULBOUS PLANTS FROM SEEDS.

By HERR MAX LEICHTLIN, Carlsruhe, Baden.

I NOTICE, at page 55, of THE GARDEN, a query as to the way in which seedlings of Liliaceous plants should be grown, or, rather, what management is required to keep the seed-pans clear of Moss, and ensure germination of such seeds as lie a considerable time in the soil before they germinate. Those experienced in such matters know that the different species of one and the same tribe, or genus, require one and the same time to germinate; this, however, is only a general rule, to which there are some exceptions, more especially in regard to Lilies; but, *Calochorti*, *Amaryllids*, *Gladioli*, and *Erythroniums*, for instance, no matter of what species the seeds may be, will all start to grow about the same time. With respect to Lilies, all the rhizomatous-rooted ones, like *L. superbum*, and *canadense*—in fact, nearly the whole of the American species—take a whole year to show their first seed-leaf. The same holds good with all *Martagons*, with the Indian species, and the speciosum section. *L. Szovitzianum* and *monadelphum*, Caucasian species, form, in from six weeks to two months after having been sown, little bulblets under ground without showing their seed-leaf. Seeds of Liliaceæ, in most cases, are comparatively large, and are not particular as to the depth of soil which is put over them. I, therefore, rather like to sow them somewhat deep, but I always have the soil that is put over them finely sifted,

in order that the first leaf may not find any difficulty in pushing through it, or even through the Moss, if there is any. If, in the course of a year, the Moss on the pans has formed itself into a hard crust, I carefully remove it, giving a little top-dressing of fresh sifted soil, and the seeds begin to germinate soon after this, that is to say, exactly at the time when the parent plants start into fresh growth. *Gladioli*, one and all, dislike having their seeds buried; they must be sown on the surface, and covered only with a little *Sphagnum Moss* finely cut; unless this precaution is taken, they come up sparingly. Of course, old Cocoa-nut refuse, or worn-out tan from a hot-bed, might answer the same purpose, and might even be useful as a preventive against the growth of Moss. If the seeds, as in the case of some kinds of bulbous plants, are large enough, I even like to entirely renew the soil in the seed-pan in which they are sown, taking out the stratum wherein the seeds are imbedded, and washing the soil clear away from them by gentle movements in a sieve under water, so as to loosen and dissolve the soil by degrees into small particles. By thus sifting under water, the seed is left unhurt, a matter of some importance, especially if it has begun to grow. As a rule, the best way is to sow seeds of bulbous plants at once when ripe; but, if maturity takes place late in the year, say in October or November, it is preferable to wait until January before sowing, because, if sown so late in the season, the seedlings do not gain sufficient strength to withstand the winter, but, on the contrary, are apt to perish in dull damp weather. I may add that, with care, seedlings of bulbous plants may be transplanted safely even in the midst of their vegetating period.

Variegated British Ferns.—In the article on variegated Ferns (see p. 52), *Scolopendrium vulgare variegatum* is described as a dwarf variety. You will see from the frond I enclose, which is from one of three distinct variegations of this species I have found myself, that it is of fair proportions. I have another quite large form, but the fronds are not at present in a fit state to send. While on this subject, I may add that I have found five distinct variegations, all constant, of *Polystichum angulare*, and one of *Polystichum aculeatum*; my plant of the latter I believe to be unique. Of *Lastræa Filix-mas*, *Blechnum Spicant*, and *Pteris aquilina*, I possess variegated varieties. I forward for inspection specimens of *Polystichum aculeatum* and some of the *P. angulare* variegations. I should observe, however, that the colours or markings are much brighter in the young growth than in the ripe state.—J. M., *Hawkchurch, Axminster, Devon.* [The variegations in question are distinct and beautiful, especially those of the common Hart's-tongue.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Fuchsia Trial at Chiswick.—It should be remarked in reference to this trial that the names attached to the varieties, do not denote the names of the raisers, but of the growers who sent them for trial. Of the kinds enumerated (see p. 89), four were raised by us, and one by Mr. Banks, and sent out by us, viz, Crown Prince of Prussia, La Favorite, Wave of Life, Weeping Beauty, and Noblesse.—E. G. HENDERSON & SON.

Yucca Off-sets.—At what time may I cut off-sets from *Yucca gloriosa*? I want to increase my plants of it; but I am afraid of taking them from the parent-stem, not knowing the right season at which this may be done.—J. H. W. T. [Remove your off-sets in March, cut their bases clean with a sharp knife, and insert them firmly in a good yellow loamy soil. Neither sand nor leaf-soil need be mixed with the earth, and they may either be rooted in pots or boxes, in frames, or in the open ground.]

Lilies from Cuttings.—Mr. Barr increases his Lilies in some cases by means of cuttings, made of the tops taken off before flowering. Some taken off last year, and inserted in pots plunged in a gentle bottom-heat in frames, have rooted well and have now formed nice bulbs, about the size of marbles. Lilies may, therefore, now be increased in at least five different ways, viz, by means of bulbs at the roots, scales of the old bulbs, bulbils found on the stems, cuttings, and seeds.—F.

Plants in Bloom.—The following are now in bloom in the open air at Weybridge Heath, viz:—*Cyclamen Atkinsii*, *C. Coqm* and its white variety, *C. verum*, *C. ibericum*, *Iberis Gibraltarica*, *Arabis procumbens*, *Aubrietia deltoidea*, *Hepatica angulosa*, *H. single mauve*, *H. single pink*, *H. single blue*; *Primroses* (including *Primula denticulata*), *Lithospermum prostratum*, *Erica carnea* and *Codonoides*, *Daisies*, *Yellow Crocus*, *Eranthis hyemalis*, *Christmas Roses*, *Colchicum autumnale flore pleno*, *Jasminum nudiflorum*, *Lonicera fragrantissima*, and *Czar and Roman Violets*.—GEORGE F. WILSON, *Heatherbank.*

Argemone hispida.—The Prickly Poppies in common cultivation are of annual duration only. This species is perennial in its native habitat, the dry plains lying between the Mississippi and the Rocky Mountains; but whether it will prove of the same duration in our climate remains to be tested. It is a most showy plant, growing to a height of 2½ to 3 feet, with glaucous spiny foliage, and numerous large pure white flowers. It has, however, one defect, that of requiring, like so many other American perennials, to be sown as soon as ripe, otherwise the seed remains dormant some time before vegetating. It will probably prefer sandy soils to such as are of heavy nature.—W. S.

GARDEN STRUCTURES.

MR. LASCELLES'S HOUSE-TOP GARDEN.

MR. CHARLES READE, with his accustomed clearness and vigour, has written a good deal to prove the house-top, as at present arranged, a death-trap; and so it has proved to many. For some time past, an idea has obtained that the garret storey, now the least attractive, might, without much extra expense, be made the pleasantest in the house. Mr. Read held that the roof itself should be as easy of approach as any other floor in the house, and that, with a flat properly-constructed roof, surrounded by an ornamental railing, the house-top would, in fine weather, prove an agreeable airing place for the household. A step further, and we have the house-top garden, or the house-top conservatory. There can be no doubt that the proper carrying out of this idea, in a variety of ways, would prove one of the most agreeable innovations ever made in gardening. To Mr. Lascelles, the horticultural builder, of Bunhill Row, Finsbury, belongs the credit of first showing us what may be done in this way, even in the heart of London. The roof conservatory forms the roof-storey of Mr. Lascelles's offices; the floor of the conservatory, which is on a level with the bottom of the cornice shown in our illustration, forms also the roof of the storey beneath, is well formed of concrete, with iron imbedded in it, to secure all the needed strength. Brick beds have been formed round the sides of the house, and these contain earth for Vines, which cover the roof. The surface of these beds forms a convenient standing-place for plants in pots. The house is of wood, bent by the aid of steam, and well, but not expensively, constructed, and the effect from the street is very good. The glass is not bent, although it is so in appearance. With dense shade overhead, a house of this kind would form a Fernery, and, without such shade, fruits that endure a dry atmosphere might be grown after the orchard-house fashion. Abundance of water would, of course, be required in any case, but this would not lead to much inconvenience, as the ordinary supply to the house could be made available by the cistern being placed on the conservatory floor. The roofs of large public buildings, such as theatres, would afford capital sites for winter gardens on a large scale; water in abundance is required on such roofs, and that is the

Mr. Lascelles's Office Plant-case.

Section of Office Plant-case.

Mode of Heating Office and Case by Gas.

chief requirement of the plants. In such cases, the winter-garden would form a new and most attractive feature of the establishment. As regards business houses, a modification of the same plan might be desirable, where very good light was required in the upper storey. Such a pleasant innovation in the city naturally suggests many ways in which a like kind of glasshouse might be made to add to the comfort and elegance of private houses of every class, from those who could afford a

well-furnished winter-garden to those who could only use the upper storey as a playground for children. We are assured that the architectural difficulties (even in the present state of our knowledge of the subject) are surmountable. The ordinary square type of glasshouse would, of course, be undurable over any handsome house. The fact, however, that Palms, and many other sub-tropical plants suited for decoration, thrive perfectly in a less brilliant light than that of a common greenhouse, would relieve the architect from the necessity of making the roof a glass shed. If the approaches to the con-

servatory floor were, as they should be, roomy and convenient, the difficulties of moving the soil, plants, &c., would not be so great, as they might, at first sight, appear. This, however, seems a case to which the principle of "co-operation" might be advantageously applied, and we commend the suggestion, for what it is worth, to the attention of those who are interested in the matter. Suppose, for instance, a builder is about to

erect a row of a dozen or so of good large houses, each of these might be furnished with its conservatory on the roof communicating with the conservatories of the houses on both sides, so that the whole would form one continuous greenhouse, uniform in height and architecture, and so presenting a much more pleasing appearance, when viewed from the road or street, than if the conservatory of each house was detached and built in a different style. This would form a very fine winter-garden, common to all the inhabitants of the row or block of houses, much

in the same way, as is at present the case with many London gardens now. One consideration in favour of the house-top conservatory is the facility with which it might be heated; for temperate-clime plants the always ascending heat of the house would suffice. It could be kept in excellent order by one gardener, paid by subscription from each family, who would thus, at a trifling expense, enjoy all the advantages of an extensive first-class

winter-garden on their own premises, as it were. Another point gained would be that, by the use of one common lift (constructed while the houses are building), soil, plants, &c., for the entire row could be raised to the roof, and thus spare each family the trouble and inconvenience of having such things carried up through the house. Some persons, from a desire of complete privacy, might object to this arrangement; but we believe that, considering the many advantages which it possesses, others may be induced to give it a trial, and it is, at least, one deserving of some consideration.

On our visit to the busy establishment, above alluded to, we were particularly struck with a Fernery or plant case which runs the whole length of the front windows, seven in number, and is heated by a small boiler placed behind the fire-place, as shown in the accompanying sketch. From this a 2-inch flow and return pipe is taken through the case, so as to heat it when required. The space around the pipes can be filled with

rarely being necessary except during severe weather. In the example now alluded to, gas is used as the heating agent, and is probably cheapest in the generality of cases. Our first illustration shows a portion of this case as seen from Mr. Lascelles's private office, and was very tastefully arranged at the time of our visit with choice Ferns, Selaginellas, Begonias, Ficus, and other decorative plants, while more recently, we believe, several species of choice Orchids in hanging-baskets have been added.

THE ARBORETUM.

THE OAKS OF AMERICA.

THE one great genus above all others in usefulness is that of the Oak. No other in the flora of the world, perhaps, contains so many valuable species in point of durability, hardiness, rapidity of growth (for the Oaks are rapid growers when once fully established),

Mr. Lascelles's House-top Garden in the City.

ark, or water, if desirable, so as to produce a moist and genial bottom-heat. The Ferns, Mosses, and other decorative plants are arranged in flat square pans of zinc or earthenware, as shown in our sectional sketch, and the effect of the whole, especially when seen from the offices within, is very effective, and affords relief to the eye which would otherwise look out on a dismal prospect of blackened roofs and soot-begrimed chimney-pots. We look on this elegant innovation as a great improvement, and think, with its originator, that, if generally adopted, the appearance and comfort of our dwellings and offices in the town would be considerably enhanced. Everyone who has attempted growing choice plants in cases must have felt the want of having them heated efficiently and at a slight cost. By placing the boiler—a very small one and of simple construction will suffice—behind the ordinary fire-grate, it may be heated at a very slight cost, the only extra expense incurred being the prime cost of the little apparatus required and the fuel necessary to keep up the heat during the night, the latter

freedom from insects and diseases, as well as pecuniary value in the market. Another item to be taken into account is their ready propagation from seeds, thus enabling us to reproduce them in unlimited numbers, at a comparatively trifling cost.

Natural Groups.

The grouping of these trees is generally well defined; so well, indeed, that an acquaintance with a single member of most of the sub-genera, is apt to convey a very accurate impression of the character of all the others belonging to it. The first of these is known as the White Oak group, and is composed of the well-known and valuable White Oak (*Quercus alba*), Post Oak (*Q. obtusiloba*), its dwarf southern form (var. *parvifolia*), Burr or Mossy-cup Oak (*Q. macrocarpa*), its western form (var. *olivæformis*), and the true Over-cup Oak (*Q. lyrata*). The second is called the Chestnut Oak group, and is composed of the Swamp White Oak (*Q. bicolor*), Swamp Chestnut Oak (*Q. prinus*), its variety, the Rock Chestnut Oak (var. *monticola*), the Yellow Chestnut Oak (var. *acuminata*), a southern form (var. *Michauxii*), and the Dwarf Chestnut or Chinquapin Oak (*Q. prinoides*). We next have what might be termed

the Live Oak group, although consisting of but one true southern species and two other well-defined dwarf forms. The Live Oak (*Q. virens*) is considered to be the most valuable of the whole genus, owing to the indestructibility of its timber. The forms alluded to are the Seaside Oak (var. *maritima*) and the Tooth-leaved Oak (var. *dentata*). All of the foregoing are what is termed annual-fruited species—that is, they perfect their Acorns during the autumn of the first year on the wood of the same season. The group which might be termed the Willow Oaks form the first of the biennial-fruited section, or those in which the Acorns arrive at a perfection during the autumn of the second year. This group embraces the Upland Willow Oak (*Q. cinerea*), its dwarf form (var. *pumila*), the true Willow Oak (*Q. Phellos*), its two southern forms (var. *laurifolia* and var. *arenaria*), the Laurel or Shingle Oak (*Q. imbricaria*), a probable hybrid, Lea's Oak (*Q. Leana*), and another of the same character, most likely a sport from the true Willow Oak, called Bartram's Oak (*Q. heterophylla*). We next arrive at a small group, having thick, leathery, shining leaves, with from three to five lobes. The first is a true southern species, termed the Water Oak (*Q. aquatica*); it has also a form with longer leaves and smaller fruit (var. *hybrida*), the Black Jack Oak (*Q. nigra*); also two western forms called by Dr. Engelmann (var. *tridentata* and var. *quineloba*). Lastly, we have the largest group of all—the Black and Red Oaks. Two species belonging to this are classed by themselves, owing to the soft downy character of the underside of the leaves; these are the Bear or Scrub Oak (*Q. ilicifolia*), and the Spanish Oak (*Q. falcata*). With smooth leaves we have the southern Turkey Oak (*Q. Catesbæi*), the Scarlet Oak (*Q. coccinea*); its variety, the well-known Black Oak (var. *tinctoria*); another form, the Gray Oak (var. *ambigua*); the Red Oak (*Q. rubra*), its western form with small fruit (var. *runcinata*), the Pin Oak (*Q. palustris*); and a little shrubby southern species, the Georgia Oak (*Q. Georgiana*), completes the list east of the Mississippi. West of this great division the whole character of our flora appears to undergo a complete change, and the species of Oak bear a resemblance to those belonging to foreign countries.

Useful Species.

First, let us consider those of undoubted hardiness, such, for example, as will endure the climate of our northern and western States. Commencing with the well-known White Oak, it seems almost superfluous to attempt a description, so well it is known to every one in the country, even to the schoolboy, who eagerly gathers its nuts in lieu of a more palatable fruit. The timber is of the most durable character, firm and fine-grained; hence it is largely in demand for innumerable uses in the mechanic arts, &c. To the farmer it is invaluable, and enters into all the routine of his daily duties; his fencing material, his implements, his farm-buildings, and indeed, almost every article used in his vocation. In the market, its timber commands a high price, and is always of ready sale. The bark, is, likewise, excellent as an astringent. The Post Oak grows, so slowly, and at best forms only a second-class tree, that I am in doubt about recommending it for cultivation, and yet its fine, close-grained, durable wood is, certainly, no mean incentive to the timber-grower who is looking to the future for fencing material. It is mostly found on high dry soils, but, like many other species, will succeed on the opposite extreme, as has been fully tested. As a general rule, the drier the soil the finer grained and more durable we find the wood. The Chestnut Oak cannot be recommended as furnishing the best quality of timber, although the Rock Chestnut Oak exceeds them all in this respect, possibly on account of its higher and dryer habitat. It is, also, the best species for fuel. The form known as the Swamp Chestnut Oak, grows to a large size, and is well worthy of cultivation. The timber of the Black Oak, Scarlet Oak, and true Spanish Oak, are neither of very excellent quality, but the bark of each are of more or less value for dyes or tanning; and the latter is said to be the best of all Oaks for tanning hides. The Pin Oak ranks next to the White Oak in excellence. It is a rapid grower, makes a firm wood, which is eagerly sought after by mechanics, and thrives satisfactorily either on dry or moist lands. The Gray Oak is a true northern species, being frequently found in high latitudes, which may add an additional value to it for cultivation. The wood is reasonably durable, although not equal to most of the foregoing. The Shingle Oak, as its name implies, is used throughout the west, where it is well-known, for sawing into shingles, although its timber is not of best quality. We now reach a species that is, undoubtedly, the most valuable of the genus; but, unfortunately, it is too tender for the North and West. We allude to the Live Oak of the South. The greatest drawback to its culture is its slowness of growth, hence the exceeding compactness of its wood. It is, also, emphatically a seaside tree, being rarely found many miles from the coast.

Ornamental Species.

For lawn planting, where sufficient space is allowed for perfect

development, and where the surroundings are extensive enough to warrant the use of our largest sized trees, the Oaks are unsurpassed for this purpose. Nothing can surpass the White Oak, view it in any light we will, and although the entire genus are almost unexceptionable for ornamental planting, still, this well-known species must take preference over all others. The Pin Oak will, perhaps, come next, having rapidity of growth, grace of outline, and beauty of foliage, as leading characteristics. The foreign writers on horticulture have pronounced this species to be the finest of the genus, but we prefer the White Oak. The Scarlet Oak has so many excellences to recommend it, that I cannot conceive why it is not more frequently used. The tree is perfection itself, added to which the foliage is always handsome, whether in the green garb of summer, or tinted with its scarlet autumnal hue. Its growth is moderately rapid, and it is well suited for dry locations. The Willow Oak, with its narrow leaves, is at once curious and attractive. It always forms a prominent feature in a collection, and may be classed as one of the most desirable native trees for ornament. The Burr Oak is perhaps more curious than handsome, owing to its corky bark. It forms a medium-sized tree, and should be more extensively used. I have always felt a great partiality to the Black Jack Oak, rough and rugged-looking as it is frequently seen; its large wedge-shaped, shining, dark green leaves, contrast well in a collection. It is a small-sized tree, found mostly on dry sandy situations. Among the Chestnut Oaks, I prefer the Yellow Oak, or as some prefer to call it, the true Chestnut Oak. Its resemblance to the Chestnut tree is strikingly apparent, in fact, to the ordinary observer the two are scarcely distinguishable. It also forms a medium-sized tree, and looks well in a group on the lawn. The Red Oak, in good soil, grows to a large size, and is one of our most conspicuous trees during the autumn months. The deep, almost purplish, crimson hue, makes an effect that cannot well be surpassed. It is at all times, however, a fine tree for ornament, and should receive due regard from planters. Several other species might be mentioned, whose claims entitle them to notice, but the foregoing comprise the best.

Propagation.

All the species are easily grown from seeds, provided we give them sufficient care. Acorns should be gathered as soon as ripe, which is determined by their hold on the tree. If readily shaken off, they must be collected at once, and placed in comparatively dry sand; that is, with a very slight amount of moisture. They germinate easier than almost any of our native trees, and especially in some instances, where I have noticed them sprouting while attached to the limb of the parent tree. When the latter is the case, they must be cautiously dried somewhat before placing in sand. It does not matter about the end of the young root being either shrivelled or decayed, as the fibres will start out fresh from the base of the seed-leaves all right. In the spring, prepare level beds, say about 4 feet wide, and after sowing the seed thinly over the surface, cover slightly with sand, when a few warm days will bring the young plants through. They should be left in these beds for two years, keeping them meanwhile scrupulously clean. The first year they make but little top, but plenty of roots, and afterward the top grows rapidly. The rare forms not propagated from seed may be grown by means of grafting, as the Oak is not difficult to work. Side-grafting is preferred close to the ground, and then the soil is drawn up and pressed around the whole, allowing only the top bud to be uncovered. [The above interesting article is by Mr. J. Hoopes (in the *New York Tribune*). Mr. Hoopes is the author of "The Book of Evergreens," is well acquainted with the trees and shrubs of his country, and an able practical horticulturist, as proved by his extensive and richly-stored nurseries near the pleasant town of West Chester, in Pennsylvania. These nurseries are among the best we saw in America. Such information, coming from one who knows the trees so well, should prove useful to tree-lovers in this country, where these fine trees are too much neglected. We have observed that North American Oaks thrive well both in England and France, and regret that the finer species are not more frequently grouped on lawns and in parks. We should be obliged to any of our readers who would send us the measurements of the largest specimens of American Oaks they know of in this country.]

BEECH BLIGHT.

I OBSERVED in THE GARDEN (see p. 34) a note as to a disease or blight said to have attacked the Beech trees in Westphalia of late, and which is there described. A similar blight or disease showed itself on Beeches in my grounds at Hickleton, near Doncaster, nine or ten years ago. The soil is magnesian limestone. It has appeared on several trees, old and young. In the old trees the bark decays and comes away. One tree, attacked some

years ago, appears to be recovering. Half another very fine tree is dying. Young bark sometimes appears on the edge of the dead wood. Ungues appear on the decaying wood. The young sprigs die. On the younger trees no apparent symptoms of decay have appeared. I have heard of similar symptoms having appeared on the property of a friend of mine, on Beeches, in Yorkshire, growing on chalk. No apparent cause for the disease has been discovered. The notice, to which I have referred, does not suggest any cause or any remedy. I shall, therefore, be grateful for any information as to the supposed cause, or any remedy for the disease. The oldest trees affected may be between one and two hundred years old, the youngest from fifty to sixty.—HALIFAX, *Belgrave Square*.

[On submitting this communication to Mr. Murray, we have received the following reply:—"I have nothing to add to what I have already said regarding this 'blight' in reply to Mr. Monius' inquiry, except, perhaps, to say that as to the amount of injury done by this insect, Lord Halifax's letter contains more information than any that I have hitherto met with. I remember in the year 1861 being consulted by the late Marquis of Salisbury as to the best mode of treatment of some Beech trees of his that were attacked by (I think at Hatfield). The trees were on one side as white as snow (a block was sent to the Horticultural Society), and, perhaps, the present Marquis or some of his people may remember the trees, and could tell in what state they are now, so as to enable us to follow the progress of the mischief."]

The American Larch.—This was introduced to us early in the eighteenth century; but, even in the present, it is but rarely to be found in any plantation, wood, or forest, in this country. Compared with the European Larch, the American kind is inferior in quality of timber, and is a less beautiful tree; but the common Larch, in its present diseased condition, cannot be depended upon to produce good, sound, and perfectly matured timber, and it can only be profitably cultivated with a view to quick returns in the shape of hop-poles, fencing-rails or pailings, pit-props, railway-sleepers, temporary buildings, or other ordinary rural purposes; therefore, until we can obtain new and healthy progeny of the European Larch, I would recommend the American Larch as a useful and profitable, though coarse-bodied, tree, for the climate of Great Britain and Ireland. It is really hardy, and of equally rapid growth, with the common kind, and quite as accommodating as to soil and situation, and would produce equally quick returns in poles, &c.; though, as I have stated, the wood is somewhat coarser. Its cones and foliage are smaller than those of the common Larch, and its branches longer and less regularly disposed. There are several forms or varieties of it, the whole of which are hardy and useful enough in elaborate ornamental planting.—J. N.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Elder v. Flies.—I have heard it stated that common Elder, planted near dairy arder windows, will prevent the ingress of flies. Will some of your correspondents, therefore, kindly say whether or not that is the case?—W. N.

Picea Parsonsi.—This is, without doubt, one of the most beautiful, if not the most beautiful, of Californian Firs ever introduced. The extraordinary growth of the leaves, which are incurved in a peculiar manner, displaying the very green of the under surface, the wonderful vigour, rapidity of growth, the beautiful regularity of the branches, which in most cases are arranged in whorls at the end of each year's growth, combine to render it one of the most lovely of its tribe. In hardihood it exceeds many of our indigenous trees, having stood the frosts of 1860-1-4, and the extraordinary frost of the 1st of June, 1865 (when many Larches in the neighbourhood were completely killed), not a leaf being injured.—W. BARRON, *Borrowash*.

Seedling Araucarias from Scotch-saved seed.—It is worthy of notice, that at Castle Wiff, Wigtonshire, two Araucarias, male and female, were plentifully covered with cones in the summers of 1872 and 1873. Mr. Fairgrieve, gardener to Lieut.-Col. Hathorn, having carefully manipulated these, the seeds were saved. He sowed them under glass early in November, and, when I was on the 10th inst., several strong young plants were showing above ground. I believe I am right in saying that these, if not the first raised from Scotch-saved seed, are, at all events, the first from Scotch seed. Will you give your opinion in reference to this point?—SALMONICERS. [We are not aware of any other instance in which Araucarias have been raised from Scotch-saved seed; but Messrs. Lane have raised seedlings in abundance from seeds saved from trees in their nursery at Berkhemstead in Hertfordshire.]

The Cherry Plum.—Cuttings of this are struck extensively in the nurseries of Messrs. A. N. Baumann et fils, at Bollwiller (Alsace), where they are used as stocks for different kinds of Plums to form dwarf trees, as espalier, &c., for which purpose this *Prunus* is well adapted, and much used in the large nurseries in France. The treatment they require does not differ in any way from that of other cuttings of deciduous trees; that is, they are cut to about 1 foot long, having at the base an eye or knot, and are inserted in good soil so that about two or three eyes may be visible above the surface of the ground. As for the time, I would state that we used to cut them, as well as the cuttings, all through the winter; using the wood of plants which had budded during summer, and had been cut back over the inserted eye. I found that the early-made cuttings struck more freely than the later ones, and that the advantage the former had of becoming callused during the winter. *Unink, Ealing*.

THE LIBRARY.

THE LITTLE FLOWER SEEKERS.*

THIS is a very elegantly got-up book. Paper, printing, binding, and illustrations, are all of the best, and the letter-press contents are agreeably written. The illustrations comprise twelve chromographs, representing flowers in their natural colours, and mostly of their actual dimensions. They are copies from originals, in water colours, by W. H. Fitch, W. French, and F. E. Hulme. It is a pretty present for children.

THE AMATEUR'S GREENHOUSE AND CONSERVATORY.†

THIS is intended mainly for the use of amateur and villa gardeners who possess a greenhouse or conservatory in addition to their little outdoor gardens. It is written in a popular manner, and contains many valuable hints on the erection and heating, as well as on the after management of plain and ornamental conservatories, and moderately cool plant-houses. The different cultural details are set forth in a pleasing manner, each popular greenhouse or florist's flower having, in most cases, a separate little paragraph or chapter to itself. This renders the book handy for occasional reference, and we have but little doubt as to its proving useful to the hundreds of amateurs who

Love a garden and a greenhouse too.

Propagation, suitable soils, and manures, find a place in it, as well as directions for potting, watering, and the other ordinary but needful operations of a garden which are required daily, and by which the amateur gardener is frequently puzzled. There is also a calendar of hints and operations arranged for each separate month of the year, which will doubtless prove acceptable to beginners. The book is illustrated by coloured plates and numerous wood engravings, the latter being very variable both as regards subject and general excellence.

THE PREPARATION AND MOUNTING OF MICROSCOPIC OBJECTS.‡

THIS useful little volume will be found to contain very full and plain instructions on the subjects of which it treats. It is a matter of no little importance to the investigator with the microscope to be able to prepare and mount his objects properly, as on this very much depends his power of examining them with accuracy and precision. In these matters he will find Mr. Davies's book an excellent guide. As an example of the manner in which the various subjects are treated of, we quote the following extract:—

Somewhat approximating to the forementioned phenomenon [the circulation of the blood in reptiles, fishes, insects, &c.], is the rotation (or cyclosis) of fluid in the cells, or, as it is usually termed, the circulation of the sap, of plants. This is shown in certain vegetable growths as a constant stream of thick fluid, wherein small globules are seen; which stream flows round the individual cells, or up the leaf, turning at the extremity, and down again by a different but parallel channel. There is little or no difficulty in showing this in many plants; but some are, of course, better than others, and require a different treatment; we will, therefore, notice a few of these. Perhaps the best of all is the *Vallisneria spiralis*, which is an aquatic plant, frequently grown in, but not really belonging to, this country. As it somewhat resembles Grass, the leaf is not used in its natural state, but a thin section cut lengthwise with a razor or other sharp instrument; this section, however, is much better when the outer surface has been first removed. It should then be laid upon a slide with a drop or two of water, and covered with a piece of thin glass. Often the cutting of the section seems to be such a shock to the leaf that no motion is visible for awhile, but in a short time the warmth of an ordinary sitting-room will revive it, and with a quarter-inch object-glass the currents will be rendered beautifully distinct. Where the stream is unusually obstinate, the warmth may be slightly increased, but too high a heat destroys the movement altogether. In the summer, any of the leaves shows this

* "The Little Flower Seekers." By Rosa Mulholland. With coloured illustrations. London: Marcus Ward & Co.

‡ "The Preparation and Mounting of Microscopic Objects." By Thomas Davies. London: Robert Hardwicke, 192, Piccadilly.

circulation very well; but in the winter the slightly yellow ones are said to be the best.

The *Vallisneria* requires to be cut in sections to show this circulation; but there are many plants of which it is but necessary to take a fragment and lay it upon the slide. The *Anacharis alsinastrium* is one of these; it grows in water, having three leaves round the stem, then a bare portion, again another three leaves, and so on. One of these leaves must be plucked close to the stem, and laid upon a slide with a drop of water. Thin glass should be placed upon it, and along the mid-rib of the leaves the circulation may be seen most beautifully when a good specimen has been chosen, but it requires rather more power than the *Vallisneria*. This plant is very common in many parts of the country, a great number of our ponds and streams being literally choked up by it. In the *Chara vulgaris* and two or three of the *Nitellæ*, &c., this phenomenon may also be seen with no preparation except plucking a part from the stem and laying it upon a slide, as with the *Anacharis*. In using the Frog-bit, the outer part of the young leaf-buds must be taken to obtain the best specimens for this purpose, but a section of the stem will also show the circulation, though not so well. The plants before-mentioned are all aquatic, but the same movement of the globules has been observed in several kinds of land plants, as in the hairs upon the leaf-stalks of the common Groundsel; but these do not show it so well, nor are they so easily managed as the preceding.

THE TREASURY OF BOTANY.*

ALTHOUGH botany, as a science *per se*, is not brought forward in our pages, we are always anxious to give prominence to those features which bear upon the horticultural profession. Indeed, while fully admitting that a man may be a first-rate gardener, and yet know nothing of scientific botany, it is in every way desirable that science and practice should go hand in hand as far as possible. The botanist learns much from the gardener, and the gardener need not hesitate to acknowledge a similar debt to the botanist. The work under notice is an admirable example of a book which, while strictly botanical, is nevertheless one which should be on the shelves of every gardener who has a library, however small. We know of no single work which gives so much compendious information as may be found in the "Treasury of Botany;" nor do we know of any scientific publication which is at once so cheap and so thoroughly trustworthy. The horticulturist, who may wish to supplement his practical knowledge with the botanical history of a genus will, in most cases, find a sufficient account of it in this book. In the present edition, a supplement is added of nearly a hundred pages, mainly contributed by Dr. Masters, Mr. Jackson of Kew, Mr. James Britten of the British Museum, and Professor Dyer; and almost every page indicates, by the alterations which occur upon it, a conscientious and successful effort to bring the work up to date. The price of the two volumes, however, remains the same. The work is well illustrated throughout with steel engravings and numerous woodcuts, which add considerably to the value of the descriptions given, and it moreover includes a very complete glossary of botanical terms. One of its most peculiar and useful features is the ample and satisfactory list of the French names of plants, given in alphabetical order, with their English equivalents. We have much pleasure in confidently recommending the "Treasury of Botany" to our readers.

Garden Trespassers and their Punishment in Japan.—

In a long list of new Japanese "Ordinances" directed against minor offences punishable either by fines or imprisonment, we find the following pertaining to gardens and other rural matters, viz.:—"Gathering Sea-weed, or other water plants, on the property of another person, without his permission; stealing Bamboo or Mushroom out of another man's field; doing damage to any dyke, or beach, excavate in any field or garden, &c., belonging to another; cultivating vegetables by the road-side, or making a dust-heap, thereby causing an obstruction; cutting Grass in a field or meadow belonging to another village or person; cutting, breaking, or otherwise injuring any trees, or plants, in any public or private garden or ground; leading a horse or ox across a garden or other place, thereby destroying plants; causing any obstruction at the places used for drying edible Sea-weed; damaging Bamboos or trees, or gathering fire or brush-wood on another's land; damaging or destroying another person's fence; damaging any trees or plants on any road; allowing one's horse or oxen to trespass and damage any crops or garden; setting fire to any wood, or Grass, &c., on any mountain, plain, or field; throwing stones, tiles, sods, sticks, or any other matter, into any field or garden; picking any flowers or plants that are public property, or breaking or damaging any plants in any public garden."

* "The Treasury of Botany." Second Edition, with Supplement. Longmans & Co. 1874.

THE GARDENS OF ENGLAND.

ALNWICK CASTLE.

THIS fine old baronial residence of the Dukes of Northumberland has features and surroundings peculiar to itself. In approaching it from the railway station, we have to pass through the crooked and irregular streets of the ancient town of Alnwick, in which, on either hand, stand rude erections of the past, not the least conspicuous amongst them being the old gateway through which we pass on entering the town. It is the last remnant of the old wall that enclosed the place when the rude Northmen were more expert at the bow and spear than they were at the plough or pruning-knife. After wending our way along a short and narrow street, we find ourselves very unexpectedly in a large open space right in front of the castle. As we look upon it for the first time, our mind is carried back to a period when our modern ideas of a combination of the arts of architecture and gardening were never dreamed of. As we look upon the time-worn battlements that surround both it and the ancient gateway through which the stout Earl of Northumberland

With fifteen hundred bow-men bold, all chosen men of might,
Who knew full well in time of neede to ayme their shafts aright,

went forth to kill the fallow deer upon the far-famed Cheviot Chase, we experience a feeling of thankfulness that so grand a memorial of the past has been spared to us, and that no attempt has been made to introduce modern innovations, in the shape of flower-beds, upon the green sward that surrounds the castle; and it is with feelings of pleasure that we look down from the battlements upon a landscape every way in keeping with the noble building. Right below, the river Aln (with numerous water-fowls floating upon its surface) winds its way eastward to the sea through a vale rich in the varied beauties of nature. A path from the castle leads down the steep incline to the river side, where it conducts us to what is called "the dairy grounds." A more sylvan and enchanting spot than this is seldom seen, indeed the only place I know to compare with it is the far-famed woods of Hawthornden or Roslin on the River Esk, near Edinburgh. From the "dairy grounds" we cross, by a pretty bridge, to the north side of the stream, a shady walk leading us to the Abbey grounds. The tower and gateway of the building are still standing. At about 200 yards distance the old Abbey mills are still at work, doubtless occupying the very site of the mills that ground the corn of the monks, for many years after the foundation of the Abbey, in the year 1147. The monotonous splash of the ponderous water-wheel and the music made by the water falling over the weir, complete a picture of romantic scenery rarely met with. The Alnwick Horticultural Society have the privilege of holding their annual show on this charming spot; the beautiful haugh or holm that stretches from their tents for half-a-mile up the left bank of the stream makes a promenade for the numerous visitors that attend the annual gathering which they seemingly enjoy much. Many walks radiate from it that leads to all the objects of interest within the park, amongst the most notable are the fine ruins of Alne Abbey, a tradition exists that it was founded by a crusader who selected this spot as bearing a resemblance to Mount Carmel, the river Alne having a resemblance to the Kishion that runs under Carmel. Another interesting spot for visitors is that where Malcolm, King of Scotland, was slain when besieging Alnwick Castle in the year 1093, a cross marks this interesting spot, and it is with reluctance that we retrace our steps to seek the more modern gardens belonging to the castle, which, like the castle, unexpectedly appears before us in all their autumn glory. We soon see from the very nature of the locality, that it has taken all the practical skill and ingenuity of the landscape gardener to make the flower garden what it is. Hedged in on the western and north-western sides by the old town of Alnwick, from which the ground slopes irregularly to the east—where it is enclosed by a Peach-wall, well covered with fine young trees just beginning to bear excellent crops—a broad border along the base of this wall is very striking and effective, when filled, as it has been this season, with choice bedding plants. A large and lofty conservatory divides it in

early equal parts, the promenade along the border leads into the conservatory. At either end another noble promenade runs from it right up the whole length of the flower-garden, dividing it into nearly equal portions. Looking from the conservatory, the visitor obtains perhaps the best general view of the flower garden. From its arrangement and situation the flower-beds have to be large to give them effect, and as the eye runs up the centre walk, which becomes rather steep at the higher end, it is arrested by the pleasing effect produced by a chain of beds filled with evergreens, and arranged in the form of drapery along the face of the steep green terrace that overhangs the garden. Looking down from the higher end of this centre walk, the whole of the flower garden is seen to good effect; and, if the visitor is lucky enough to see it under such circumstances as we happened to do, upon a lovely afternoon in the last week of September, he will carry away a mental photograph not easily effaced. Until Mr. Ingram undertook the management of the gardens here, about six years ago, no attempt had been made, believe, in the way either of winter or spring flower gardening, or had sub-tropical plants been used to any extent in the decoration of the

flower gardens, and, considering the short time that such plants can be grown in the open air, in the north of England, the result has been, upon the whole, satisfactory, and a new and attractive feature has been added to the flower garden here. The same may be said of the spring garden; indeed, it has been so pleasing and attractive that I believe Mr. Ingram is now devising ways and means to carry out his spring flower gardening upon an extended scale: Violets, Primroses, and all hardy bulbous plants, with a host of other spring flowers that might be named, thrive wonderfully here, and seem to require their

lightest tints under a northern sky. Either from necessity, caused I presume by local circumstances, or from the idea that fruit and flowers ought to grow together, all the forcing-houses are within the flower garden. They are the noble houses made of iron, curvilinear in shape, which makes them externally light and pleasing to the eye, and everything has been done to make them harmonise with their surroundings, so that the visitor, who threads his way through them upon an autumn day, will pronounce them not the least pleasing feature of the flower garden. Grapes, Peaches, and pines, are all grown here to perfection, which will be noticed in a future number. Mr. Ingram began his operations in this department by lifting and renewing the whole of the Vine borders in succession, and the result has been most satisfactory. A seedling Grape raised here was pointed out to me which, I think, possesses points of merit sufficient to recommend it to the approval of a fruit committee. A Fernery and long span-roofed stove and greenhouse filled to overflowing, and just outside the flower garden, and here one can see indications that Mr. Ingram has not forgotten his old favourites the great number of fine young stove and orchidaceous plants

which he cultivates. His Grace the Duke of Northumberland kindly opens his grounds to the public one day in the week, and I can assure any of your readers, who may wish to visit them, that they will find a day spent at Alnwick Castle both pleasing and instructive.

J. T.

NATURAL ROCKERY PRODUCED BY EXCAVATION.

As a garden feature, natural rocks, *in situ*, produce an effect with which no building up of artificial rockwork, however artistically managed, can ever compete. There is a breadth, and simplicity, and grandeur in pure nature, especially as regards masses of rock, that can scarcely be imitated; but those compositions of artificial rockwork which approach natural models most closely are always the most successful. A natural rockery produced by excavation can scarcely compete with one in which masses of rock have assumed their grand natural forms above the surface; but if accidental cleavages are left undisturbed, and massive projections sought for and carefully turned to account, the effect of a rocky valley may be very successfully attained. A very

good example of rockwork, formed by excavation in a rocky soil, is that which has been recently brought to light in the Botanical Garden of Birmingham. I have incidentally mentioned this successful piece of rockwork in a previous article on garden rockwork, but I did not state how extensive it was, nor how successfully it is clothing itself with vegetation of a suitable and picturesque character. The excavation was originally made for the purpose of getting out material for raising some of the lower portions of the gardens, and was subsequently used as a great rubbish-pit. The members of the garden committee

Alnwick Castle from the River Alne.

eventually, and, in fact, quite recently, conceived the idea of converting that portion of the garden, which had been "planted out" as an eyesore, into an attractive feature. The old red sandstone lies at only a few feet below the surface of that part of Warwickshire, so that the entire sides of the excavation are composed of great masses of the natural rock; and as it has remained in a rough and untrimmed state, the main forms are very grand and picturesque; and now, with the foliage of carefully planted trailing plants, drooping tufts of Ferns, and a variety of rock plants made to nestle in snug nooks and along tiny ledges, the general effect begins to be very attractive. Drooping mantles of Ivy and Bramble drape a portion of the more bare and flat surfaces of the vertical rock, while on the more salient projections masses of Foxglove, Verbascum, and some of the finer Thistles have been established with excellent effect; the flooring of the valley being enamelled with Primroses and Violets, which play their parts with their softly contrasted colours in the spring, along with Saxifrages and other early flowers; while summer and autumn furnish an equally attractive and beautiful series of many beautiful kinds of alpine plants.

THE HOUSEHOLD.

MR. BRIGHT ON INDIAN CORN.

A MERCHANT having addressed a letter to the Right Hon. John Bright, urging the importance of introducing Indian Corn as an article of food for the people of this country, received the following reply:—"Dear Sir,—I duly received your interesting letter of 28th April last, and I have submitted it to Mr. Buckmaster, who has been giving lectures on cookery at South Kensington, and have asked him to consider how far anything can be done on the subject of the use of Indian Corn in this country. Hitherto nothing has been done, and there are difficulties in the way which it will take time to overcome. The greatest difficulty is that which attends all new things—the indisposition of the people to give a favourable, or even an impartial, attention to what is new. The chief hindrance to the use of Indian Corn has always been the want of knowledge as to the various modes of cooking it. I speak now of those who are favourably disposed towards it. There must be men and women in this country who are familiar with this branch of cookery as practised with you, or, if not, it would not be difficult to engage some American man and woman cook who would undertake to instruct in it. I shall probably see Mr. Buckmaster again when I go up to London, and I shall urge him, and those with whom he is associated, to arrange for some provision by which all that is known in the States with respect to Indian Corn may be also known in this country. We have always to import a large portion of our food, and it seems very strange that an article of such great consumption with you should be so very little favoured or known among us. I cannot say more on the subject now, but I will not forget it, or your letter upon it. "JOHN BRIGHT."

[A more important question still is, why do we not use the Indian Corn in a green state, as the Americans and Canadians do? Though we seldom ripen the grain here, in all parts of the southern counties we might grow the "Corn" to the green state with ease. A more delicious vegetable food than "green Corn" we are not acquainted with.]

The Best Way to Cook Chestnuts.—Place the Chestnuts in a saucepan of cold water, and boil till they are soft; then puncture the skin of each with a knife, and toss in a frying-pan till they become dry and mealy.

To Prepare Haricot Beans.—Soak them four-and-twenty hours in luke-warm water, then put them in a saucepan with plenty of water, with a little salt and a piece of butter, lard, or dripping, and simmer gently (not boil) for three hours; strain them, and place them in a Yorkshire-pudding tin under meat, so as to let the gravy drop on to them for a quarter of an hour.

Medlar Jelly.—Take Medlars when they are quite ripe, wash them, and put them in a preserving pan, with as much water as will cover them; let them simmer until they have become a pulp, then strain them through a jelly-bag, and to every pint of liquor add three-quarters of a pound of loaf-sugar, and boil an hour and a half. Or the jelly may be made thus: When the Medlars are quite ripe, bruise them and put them in a large stew-pan, cover with water, and boil half-an-hour, then strain through a flannel bag; to a pint of juice add three-quarters of a pound of lump-sugar, boil the juice three-quarters of an hour, then put in the sugar and boil it twenty-five minutes. Another plan: Put the Medlars in a pan and cover them with water, boil to a pulp, then strain through a cloth, and to every pint of the liquor add one pound of lump sugar, and boil the same as Apple or Currant jelly. When Medlars are scarce, a second supply of water may be added.

NOTES AND QUESTIONS ON THE HOUSEHOLD.

Worcester Sauce.—Can any of your correspondents inform me how I can make a sauce resembling in flavour the Worcester sauce? I have plenty of Shallots.—D.

Preserve Jars.—Fruits and vegetables should never be preserved in tin vessels; the acids attack the solder, and produce soluble lead salts, which are very poisonous. Glass vessels are the best for the purpose.—T. H.

Good Coffee.—To produce this with certainty at all times has long been a desideratum with many. I have tried many ways of extracting the aromatic virtues of the Coffee berry, but never succeeded to my satisfaction so well as with Ash's Kaffeekanne (sold at 315, Oxford Street), and this little contrivance I heartily recommend to lovers of good coffee.—A. F. [We have tried the contrivance and find it invariably successful in the production of good coffee.]

The Potato as a Cleanser.—Dr. Elsner states, according to the *Journal of the Franklin Institute*, that the accidental use in his household of the water which had been employed to boil Potatoes for cleaning silver-ware, led to the unexpected result that this was much superior in its cleansing action to the polishing powder so generally employed. It was found that by simply rubbing the article with the fine deposit of Potato-flour, it took on an excellent polish, without the disagreeable necessity of subsequently using the brush to remove the material, as is necessary where powders are used instead.

THE INDOOR GARDEN.

THE CULTURE OF THE FUCHSIA.

I FIND Fuchsias very useful in the form of small plants in 60 or 32 sized pots for purposes of decoration, but even large plants might be grown in smaller pots than they often are. I need hardly mention that Fuchsias look well planted out and trained to columns, pruned closely like Grape Vines. Another mode of training is what might be termed "bush" fashion, but, in my opinion, a naturally grown pyramid is the best. Beginning with my natural pyramids, I propagate them from cuttings in January or February, and, as soon as they have rooted, pot them off singly into 60-sized pots, keeping them in a temperature of about 60°. At the end of February or beginning of March I re-pot them into 32-sized pots, placing them in a greenhouse having a temperature of about 50° by night, the day temperature greatly depending upon the weather. As solar heat causes the house to get warm, ventilate freely on favourable occasions. I place a stake to each plant, train the centre shoot upright to it, and stop the side shoots equally, so as to form a pyramid. Some varieties branch more than others, and require more stopping. In May the plants are shifted again, and the shoots stopped. If I want to grow large specimens, I keep the blooms picked off until six or seven weeks before the plants are required for exhibition. I also place them out of doors about the first week in June, under a north wall, on a bed of ashes. Syringe them on fine days, morning and evening. Manure water, such as the drainings of piggeries, cow-houses, and stables, is given to them alternately with pure water without any dilution, but care is taken to guard against its being too strong. If these plants grow as they ought to do, they are between 4 and 5 feet high in September, and proportionate at the base. If they are kept growing without flowering until the next May, by shifting them in October, and placing them in a temperature of 50° to 55° during the winter, they make grand plants.

The central stake is supported by three small copper wires fastened to the top, and tied to a wire under the rim of the pot. The number of specimens to be grown depends upon circumstances. It is advisable to have a succession of young plants annually, so that in two years the old plants may be dispensed with. They are kept in an out-of-the-way place, where frost is excluded, and are potted in February or March, but it is advisable to get them to break before re-potting. After flowering our plants, supposing them to be at the best in June, in August they are removed from the conservatory to a somewhat shady place out of doors, gradually dried off, and pruned some time about the end of the month. As soon as they begin to grow again, they are re-potted in the same pots they occupied, but the pots are only filled to within three inches of the rims, so as to allow for future top-dressing. As soon as frost is apprehended they are removed into a temperature of about 50° to 55°, for the winter quarters, and syringed, in fine weather, with tepid water which is also used in watering them. By spring, these plants ought to be 7 to 8 feet high, and resembling in shape a well-grown Wellington gigantea. The soil I use consists of equal parts of loam, peat, and leaf-mould, with the addition of some cow-dung and silver sand, and in a roughly-chopped condition, and sometimes enriched with a little bone-dust; I use half-inch bones instead of crocks. The following are a few good varieties that are worth growing, viz., Triumphant, good and free; True Blue, free; Father Ignatius, good, slow-growing, but bushy; Avalanche; Arabella, very free grower; Purple Prince, fine double; Rose of Castile, old, but good; Guiding Star; Harry Williams, and Woman in White, which is one of the best double-white sorts for flowering in a small state.

Court Garden, Great Marlow.

D. GILLET.

THE PEA-FLOWERED LADY'S-SLIPPER.

(*CYPRIPEDIUM VEXILLARIUM*).

THIS pretty hybrid Lady's-Slipper was raised by Mr. Domin in the Royal Exotic Nursery, Chelsea, where I recently saw it in flower, and took the opportunity of sketching it. It is a cross between *C. Fairieanum*, a beautiful and distinct species already figured in our columns, and the well-known *barbatum* from Mount Ophir. In its habit of growth, as well as in the form and colouring of its flowers, it is nearly exact intermediate between its two parents. The foliage has a tendency to spread out horizontally, as in *C. Fairieanum*, and it resembles that of *C. barbatum* in its dark markings. The peculiarly curved petals remind one of the former species, and the dorsal petal has the form and markings of the latter. It is a curious fact that all the hybrid Lady's-Slippers are inter-

mediate between their parents in form, colour, and general habit—much more so than are the generality of crosses between different species. The top sepal is white at its apex, and heavily streaked with purple at the base, its margins, like those of the petals, being crisped or wavy, and closely set with short dark purplish hairs. The petals are tipped with purple, and streaked and spotted with the same colour towards the base. The slipper-shaped lip is intermediate in size and form between the parents, and is of a bronzy-purple tint with deeper veins. The plant grows freely in Messrs. Veitch's Nursery, and, when more generally distributed, cannot fail to become a favourite. It grows well in fibrous peat and living Sphagnum Moss, planted in a shallow pan thoroughly well drained. Like all its congeners, it requires an abundant supply of water at the root when growing, and likes a sprinkling with a syringe overhead during hot summer weather.

Cypripedium vexillarium.

This treatment does much towards preventing the ravages of thrips and red spider during the heat of the summer months.

F. W. B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

The Lion's Tail (Leonotis).—I have been interested in Mr. Niven's account of this old-fashioned plant, and shall be obliged if you, or any of your readers, will kindly tell me where to procure it.—J. [We do not know where plants of it may be obtained, but we have raised it from seed supplied by Mr. W. Thompson, of Ipswich.]

Origin of Double Zonal Pelargoniums.—I have to correct an error committed in my letter (see p. 51), on this subject:—National and Signet were raised from seed by Mr. William Bull, of Chelsea, and sold by him in 1867. My notes prove this fact, and it is a slip of the pen that caused the mistake.—JEAN SIBLEY, Lyons.

Solandra grandiflora.—A nice specimen of this is now in bloom in Mr. Parker's nursery, at Tooting. This Solandra, though an old-fashioned plant in gardens, is now rarely seen; it has large tubular whitish blooms, and thick fleshy leaves. In spring, it should be kept in a brisk moist temperature and pinched occasionally; in summer, it should be plunged out of doors or in cold pits somewhat cramped for pot room. It this way it sets abundance of flower-buds, and, if introduced into the stove in winter, the blooms open satisfactorily.—F.

The Scarlet-fruited Abrobra (A. viridiflora).—This, though still a novelty in this country, will undoubtedly become a favourite when better known. It is a half-hardy perennial climber, belonging to the Cucurbits, with deeply cleft, dark and shining leaves, white fragrant flowers, and scarlet fruit of a pretty oval shape. It attains the height of 4 or 5 feet, and is admirable for training over low arbours and trellis-work screens about windows. It blossoms the first year from seed, early in the summer, in June or July, and, in the autumn, the fleshy roots may be lifted, and preserved in dry earth until spring.—B.

THE KITCHEN GARDEN.

REPORT ON POTATOES GROWN AT CHISWICK IN 1873.

By A. F. BARRON.

THE Fruit and Vegetable Committee, having decided upon testing the numerous varieties of Potatoes that are in cultivation, and ascertaining their various characteristics, I made application among the growers, and succeeded in obtaining no fewer than what purported to be 271 distinct varieties. These, with a few exceptions, were planted on the 24th of March, and the sets used were good medium-sized whole tubers, when these could be obtained; but in some instances they were small, and then the produce was much inferior. The ground was well dug in the autumn of the previous year, but not manured, this having been done for the crop of Peas which had just been removed. The tubers were planted in lines 3 feet apart, and 20 inches between the tubers. The plants came up regularly, with a strong growth; and on the 20th of May they were attacked by a strong frost, which cut them very much, some of them being as much as 6 inches above the ground. They soon, however, recovered and grew luxuriantly, being subjected to the usual mode of cultivation, by hoeing and earthing up. On the 29th of July the disease first made its appearance by attacking the variety called Golden Gem, spreading in a few days with great rapidity to Lapstone, Fortyfold, Red Emperor, nearly all American kinds, and the Regent class. The haulm of all these sorts was soon destroyed; and of the tubers, those of Regents suffered most severely, about nine-tenths being diseased, and of some kinds, although there was an excellent crop, scarcely a sound tuber remained. There was no variety that was not more or less diseased, those escaping with the least injury being the very early and the very late kinds. During the growing season, the collection was examined five times by the committee, and the first result arising from the experiment had been to reduce the 271 varieties to 115; and this number may be still further reduced by rejecting those that are inferior and worthless.

Series I.—Skin White or Straw-coloured.

§ 1. Long or Kidney-shaped.

Ashleaf Kidney (syn., Marjolin, Oakleaf, Duckstone).—Haulm, fleshy, spreading, rarely more than two or three from one tuber, 12 to 18 inches long; stem of a pale green colour; leaflets, large, broad, rounded, slightly cupped, bright green, shining; flowers very rare; tuber, medium-sized, long, tapering, kidney-shaped; eyes, full, situate at one end and on big knobby protuberances, giving the tuber an irregular appearance; skin, smooth, pale straw-coloured; flesh, pale yellow or straw-coloured, firm; quality, excellent; moderate cropper. First early; July and August. This is considered the old or original type.

Kentish Ashleaf Kidney (syn., Veitch's Improved, Cave's Seedling, Cambridgeshire Kidney, Nutbrown, Alma Kidney, Early May, Benson's Seedling, Shepherd's Kidney, Reynard, Nonesuch, Tory, Conqueror, Mona's Pride, Champion, Early Ranelagh, Laing's First Crop, Stillyan's Kidney).—Haulm, slender, several stems from one tuber, 12 to 18 inches long; stem, having a strong purplish tinge; leaflets, small, pointed, green; flowers, very rare; tuber, medium-sized, long, tapering, kidney-shaped, not so much knobbed as the true Ashleaf; eyes, full; skin, smooth, pale straw-coloured; flesh, pale straw-coloured, firm; quality, excellent. Excellent cropper. First early; July and August.

Myatt's Ashleaf Kidney (syn. Rivers's Royal Ashleaf; Sandringham Kidney, Myatt's Prolific, Gloucestershire Kidney, Derbyshire Prize-taker, Lee's Hammersmith Kidney).—Haulm and tuber similar to Kentish Ashleaf; flowers, pale lilac, and sparingly fertile. Excellent quality. Great cropper.

Advancer.—Haulm, slender, spreading, 12 to 15 inches long; stem, pale green; leaflets, small, pointed, pale green; flowers, very rare; tuber, short, flat kidney-shaped; eyes, full; skin, smooth, pale straw-coloured; flesh, pale, firm. Moderate cropper. First early.

Jackson's Improved.—Haulm, similar to Kentish Ashleaf; tuber, medium size, long, tapering, kidney-shaped, slightly knobbed; eyes, a little sunken, few and small; skin, rough white; flesh, very pure white, firm; very handsome; excellent cropper; first early; July to September.

Nettle-leaved (syn. A. Feuille d'Ortie, Hardy's Improved Albert, Improved Royal Albert, Carter's Champion Forcing, Early Bedford Kidney).—Haulm, slender, spreading, 1½ to 2 feet in length; stem, with a purplish tinge; leaflets, small, much curled, slightly rugose, light green; tuber, medium-sized, very long, tapering, rounded, but sometimes flat, with knobs; eyes, full; skin, smooth, pale straw-coloured; flesh, firm, pale straw-coloured. Good cropper. First early.

Early White Kidney.—Haulm, moderately strong, spreading, about 1½ feet in length; similar in character to the Ashleaf, but stronger; stem, pale green; leaflets, medium-sized, curled, pale shining green; tuber, large, of a rather irregular shape, a little knobbed; eyes, full; skin, smooth, white; flesh, white, firm. Quality, excellent. Good cropper. First early. First-class certificate.

Alice Fenn.—Haulm and habit of growth very similar to Ashleaf, about 1½ feet in length, spreading, pale green; leaflets, small, much curled, showing the under-surface; tuber of medium size, resembling the Ashleaf; eyes, few; skin, smooth, pale straw-coloured; flesh, pale straw-coloured, firm. Good cropper. First early. First-class certificate.

Little Gem (syn. Early Gem).—Foliage and general habit of growth similar to Ashleaf, but stronger, and a later grower, and stems lightly tinged with purple; 1 to 1½ feet; tuber, small, rather long, but neat kidney-shaped, with a few small knobs; eyes, full, rather large;

skin, pale straw, smooth; flesh, pale yellow, firm. First early. First-class certificate.

Early Border.—Habit and appearance of Kentish Ashleaf; haulm, very slender, about 9 inches in length; tuber, small, short, or half-round kidney; eyes, full; skin, smooth, pale; flesh, pale. Very early. Useful for frame work.

Reine de Mai.—Haulm, slender, spreading, 1½ to 2 feet in length; stem, pale green; leaflets, broad, pointed, green, slightly rugose; flowers, small, white, fertile; tuber, medium size, round kidney shape; eyes, small and few; skin, smooth, yellowish; flesh, pale yellow. Good cropper. Early.

Marjolin Tetard.—Haulm, robust, spreading, resembling Ashleaf, but much stronger, about 18 inches long; stem, pale green; flowers, white, fertile; tuber, large, very broad, flat at the crown end, and tapering like a wedge to the stalk end; eyes, full, but few; skin, smooth, dark straw; flesh, straw-coloured. Heavy cropper. Early, succeeding the Ashleaf.

Woodstock Kidney.—Haulm, robust, spreading or prostrate, about 2½ feet in length; stems few in number, dark purplish colour; leaflets, large, shining, deep green; flowers, white, fertile; tuber, medium size, rather broad, irregular-shaped kidney; eyes, few and small; skin, rough, dark straw; flesh, white, firm. Moderate cropper.

Burpitt's Bountiful.—Haulm, slender, spreading, about 12 inches in length; stem, purplish; leaflets, small (like the Nettle-leaved), deep green, but much later; flowers, light purple, fertile; tuber, medium size, short, broad, flat; eyes, few and small, full; skin, smooth, pale straw; flesh, white. Fine quality; average cropper. Second early.

Multum in Parvo.—Haulm, slender, about 12 inches in length; leaflets, small, the whole plant much resembling in general appearance a dwarf form of Kentish Ashleaf; flowers, very rare; tuber, small, short, flat, kidney-shape; eyes, small, about level with surface; skin, a little rough, dark straw-colour; flesh, firm, white. Very small cropper. Very early.

Yorkshire Hybrid (syn. Quarantine de la Halle).—Haulm, robust, about 2½ feet in length; stem, deep green; leaflets, broad, rugose, green; flowers, pale, produced abundantly, and followed by berries in great abundance; tuber, large, rounded, long kidney-shaped, tapering somewhat to each end, a little coarse in appearance; eyes, large, slightly sunken; skin, smooth, pale straw-coloured; flesh, pale straw, firm. A moderate cropper. Second early.

New Early Racehorse.—Very similar to Yorkshire Hybrid, having broader leaflets, and growing to little more than half the height. Moderate cropper.

Pioneer.—Haulm, slender, 12 to 18 inches in length; stem, pale green; leaflets, abundant, small, rugose, pointed, pale green; flowers, very rare; tubers, medium size, very irregular, kidney-shaped, coarse-looking; eyes, numerous, sunken; skin, smooth, dark straw; flesh, yellow, firm; throws the tubers out on the surface of the soil. Moderate cropper. First early.

Waterloo Kidney.—Haulm, slender, 1½ feet in length, somewhat resembling Myatt's Prolific, but having the leaflets much more crumpled; berry-bearing; tubers, large, long, tapering, and handsome; eyes, a little sunken, rather numerous, situate over nearly three-fourths of the tuber; skin, pale straw, smooth; flesh, firm, white. Excellent quality. Moderate cropper. Second early.

Dawe's Matchless (syn. Webb's Imperial, Wormsley).—Haulm, moderately strong, of somewhat spreading growth, about 2 feet high; stem, slightly purple at the base; leaflets, of medium size, deep green, and much crumpled or rugose; flowers, small, dirty white, fertile; tubers, large, long, flattened, of regular form; eyes, rather numerous, prominently diffused over three parts of the surface; skin, pale, smooth; flesh, white, firm, fine quality. A very handsome Potato; good cropper. Second early.

Excelsior Kidney.—A stronger-growing and much improved form of Dawe's Matchless, producing a larger and finer sample. Extra fine quality. First-class certificate.

Berkshire Kidney.—Haulm, moderately robust, spreading, about 1½ feet long; stem, tinged with purple; leaflets, broad, pale green, rugose, with rather short petioles; flowers, dirty white, fertile; tubers, medium-sized, flat, kidney-shaped; eyes, few, and rather full; skin, smooth, pale; flesh, straw-coloured, rather close-grained. Light cropper. Second early.

Jaune de Brie.—Haulm, robust, of erect growth, about 2 feet in length; stem, pale green; leaflets, small, rugose, like the Regent type, pale green; flowers, pale blue, very fertile; tubers, above average size, long, cylindrical, tapering; eyes, small, slightly sunken; skin, smooth, pale yellow; flesh, pale yellow, firm. Moderate cropper. Second early.

Prince of Wales.—Haulm, moderately robust, spreading, and seldom branching, about 2 feet in length; stem, tinged with purple; leaflets, large, broad, deep shining green, very distinct; flowers, pale blue, fertile; tubers, large, kidney-shape, somewhat tapering; eyes, full, at times situate on raised knobs like the Ashleaf; skin, smooth, clear; flesh, rather coarse, pale straw. A very handsome Potato, but not of good quality; average cropper. Second early.

King of Flukes (syn. Queen of Flukes, Birmingham Prize-taker, Derbyshire Prize).—Haulm, &c., similar to Dawe's Matchless, moderately robust, from 1½ to 2 feet in length; leaflets of medium size, deep green, rugose; flowers, pale blue; berries, large; tubers, large, broad, flat, of even form; eyes, full; skin, smooth, pale straw; flesh, pale straw, hard. Very handsome Potato; has the habit of growing out on the surface of the ground, many of the tubers thus becoming green. Moderate cropper. Second early.

Vanguard.—Haulm, rather slender, from 1½ to 2 feet in length; stem, tinged with purple; leaflets, deep green, rugose; similar to Dawe's Matchless, but dies off earlier; tubers, medium, short, flat; eyes, full, few in number; skin, smooth, pale; flesh, pale, firm. Moderate cropper. First early.

Beta.—Very similar to preceding, but later and inferior.

Sextus.—Haulm and foliage somewhat similar to Dawe's Matchless, of a neat, sturdy growth; tubers, medium size, short, flat, of regular form; eyes, few and small; skin, rough, pale straw-coloured; flesh, pale firm. A handsome Potato of the Fluke section. Moderate cropper.

Harbinger.—Plant of the same character as Sextus. Tubers, rather small, short, flat, and irregular in form; eyes, small; skin, smooth, pale; flesh, pure white, firm. Fluke section. Light cropper. Third early.

Lapstone (syn. Haigh's Seedling, Cobbler's Lapstone, Almond's Yorkshire Hero, Pebble White, Headley's Nonpareil, Huntingdon Kidney, Yorkshire Hero, Perfection, Rixton Pippin, Ashtop Fluke).—Haulm of moderately robust growth, from 1½ to 2 feet in length; stem, pale green, sometimes tinged with purple; leaflets, large, broad, very pale green, of a very distinct character; flowers, white, produced in great abundance, but very rarely succeeded by berries; tubers of medium size, of rather irregular form, some being kidney-shaped, others broad, flat, and some cylindrical and rounded; eyes, small, full, and few; skin, smooth, pale straw-coloured, generally having a tinge of purple at the crown, which is a characteristic feature; flesh, pale straw, firm. Very apt to supertuberate in some soils and seasons, and to continue to grow late instead of ripening off; a great cropper; of most excellent quality. Rather subject to disease. The varieties of this Potato are very numerous, but have no permanent distinctive characters. Second early; fit for use from October until May.

Fluke.—Haulm of robust growth, from 1½ to 2 feet long; stem of a dark purplish colour; leaflets, rather small, rugose, deep green; flowers, small, crumpled, white, fertile; tubers, large, generally broad, flat, of somewhat irregular form; eyes, full; skin, slightly rough, of a dark straw colour; flesh, pure white, firm. A heavy cropper in some soils; excellent quality. Late.

Model.—Haulm and foliage very similar to Fluke; leaflets, a little pointed; grows very late; flowers, white; tubers, short, broad, flat, with a blunt end; skin, smooth, pale straw-coloured; flesh, white, rather close. A very handsome Potato; heavy cropper. Late.

Amazon.—Haulm and foliage of the Berkshire Kidney character, but of somewhat stronger and later growth; height, 1½ feet; flowers, white; tubers, medium size, short, broad, flat, rather irregular; eyes, few, a little sunken; skin, smooth, pale; flesh, pale straw, firm. Moderate cropper. Late.

Utilis.—Haulm, of strong-growing Fluke character, somewhat spreading, about 2 feet long, and foliage shining; tubers, large, flat, coarse, and irregular; eyes, small, sunken; skin, rough, pale straw-coloured; flesh, pale, firm. Light cropper. Late.

Cobble.—Haulm, rather slender, spreading, somewhat of the character of Dawe's Matchless, from 1½ to 2 feet long; leaflets, broad, shining green; flowers, dirty white; tubers, large, long, flat, but somewhat irregular, the end blunt; eyes, small, full; skin, smooth, pale straw; flesh, pale, close. Moderate cropper.

Sedilla.—Same haulm and foliage as Cobble; tubers, large, flat, irregular; end, blunt or flattened; eyes, a little sunken at crown; skin, rough, dark straw-coloured; flesh, close, yellow. Moderate cropper. Late and worthless.

Clipper.—Haulm, moderately vigorous, from 1½ to 2 feet long; stem, deep green; leaflets, broad, rugose, green, flowers, pale, berry-bearing; tubers, large, long, cylindrical; eyes, very numerous, much scattered forming large knobs on the tuber, giving it a coarse appearance; skin, smooth, straw-coloured; flesh, pale straw, close-grained. Light cropper. Second early. Worthless.

Eureka.—Plant of compact growth, very robust; haulm, green, about 2 feet long, grows very late; leaflets, small, deep green, somewhat crumpled and rugose; flowers, bright purple, seldom producing berries; tubers, large, broad, flat, of the Fluke character; eyes, full; skin, pale, a little rough; flesh, white, firm. The latest of all to ripen off. Moderate cropper. Sample, very irregular.

Princesse.—Haulm, slender, spreading, but of compact growth, about 1½ feet long; stem, light green; leaflets, smooth, light green; flowers, pale blue, producing berries; tubers long, narrow, cylindrical, somewhat tapering and twisted; eyes full, very numerous, scattered over the entire surface; skin, coarse, pale; flesh, pale, firm. A peculiar but utterly worthless variety. Light cropper. Second early.

Oxfordshire Kidney (syn., Minchin's Eclipse).—Haulm, moderately robust, of erect growth, with the character of Dawe's Matchless, 2½ feet long; stem, pale green throughout; leaflets, pale green, rugose; flowers, bright blue, fertile; tubers of average size, rather short, flat, of even and regular form; eyes, few and small; skin, very rough, dark straw-coloured; flesh, pale, firm. Good cropper. Grows late. Handsome.

§ 2. Half-long.

Giant King.—Haulm, slender, of the character of the Kentish Ashleaf, 12 to 18 inches high; leaflets, somewhat pointed, rugose, with a purplish tinge; tubers, large, broad, flat, somewhat irregular; eyes, large, sunken; skin, smooth, straw-coloured; flesh, pale straw-coloured, rather close. Average cropper. Rather a handsome large tuber from so dwarf a plant. First early.

Milky White.—Haulm, slender, of spreading growth, about 12 inches long; stem, reddish; leaflets small, crumpled, like those of the

little-leaved; flowers, light blue, fertile; tubers, rather below medium size, half long, rounded; eyes full; skin, smooth, pale; flesh, very white, firm. A moderate cropper. Comes rather early into use.

Peake's First Early.—Haulm, slender, of the character of the Kentish Ashleaf, about 9 inches high, ripens off very early; tubers, medium-sized, half-long, broad, flattened, resembling Giant King; eyes, little sunken, mostly situate at the crown; skin, smooth, pale straw-coloured; flesh, yellow, rather close. A fair cropper. Very early.

Bresee's Climax (syn., Gravenstein, Coppermine, Climax).—Haulm, moderately strong, about 1½ feet long; stem, light green, erect, branching; leaflets, large, broad, pale green, frequently blotched with yellow; flowers, rare; tubers, large, long, rounded, somewhat tapering; eyes, a little sunken, rather thickly situate near to the crown; skin, rough, straw-colour; flesh, white, firm. Excellent quality, great cropper, and the best type of the American white Potatoes. Second early. First-class certificate.

Early Goodrich (syn. Bushell's Seedling).—Haulm, very similar in character to Climax; tubers, smaller, and of a coarser appearance than Climax, but much resembling it; inferior. Moderate cropper. Second early.

Springfield White (syn. Harrison's).—Haulm and foliage of the same character as Climax, but paler and of a much stronger growth, and leaflets more pointed; flowers, white, sterile; tubers, very large, half round, frequently flattened, rather coarse in appearance; eyes, large, a little sunken; skin, smooth, nearly white; flesh, close, pure white. Heavy cropper. Second early.

Bresee's Peerless (syn. Peerless).—Haulm, moderately vigorous, from 1½ to 2 feet long; stem, deep green, of the same general character as Climax; leaflets, broad, green; flowers, very rare; tubers, large, long, broad, flat, somewhat tapering; eyes, a little sunken, having a faint tinge of pink; skin, slightly rough, straw-colour; flesh, white, firm. Heavy cropper. Very handsome. Mid-season.

Bresee's Prolific (syn. Brown's Prolific Kidney).—Haulm, vigorous, 1½ feet in length; same character as Climax, but having the leaflets rather smaller; stem, pale green; tubers, large, long, flat, even, handsome shape; eyes, full, a little sunken, of a pretty pink colour; skin, thin, smooth, straw shaded with faint pink; flesh, white. A heavy cropper and particularly handsome. Mid-season.

Charden.—Haulm, very robust, branched, about 3 feet in length; stem, pale green; leaflets, pale green, rugose, pointed; flowers, abundant, pale shaded lilac; berries, few; tuber, very large, very coarse and irregular, of a long rounded form, somewhat tapering; eyes, numerous, wide, very much sunken; skin, smooth, pale; flesh, pale straw. A great cropper. A very coarse cattle Potato. Mid-season.

Golden Gem (syn. Jaune ronde hative).—Haulm, slender, spreading, from 2 to 2½ feet in length; stem, pale green; leaflets, small, rugose, green; flowers, pale; tubers, medium-sized, of a long rounded form; eyes, numerous, scattered, much sunken; skin, smooth, yellow; flesh, low, firm.

Dourie Hall Favorite.—Haulm, robust, of compact growth, about 2 feet in length; stem, pale green; leaflets, large, broad, pale green; flowers, bluish-white; berries none; tubers, medium-sized, half round, sometimes long; eyes, few; skin, a little rough, pale straw-coloured; flesh, white, firm. Good cropper. Mid-season. Very distinct.

Paterson's Victoria.—Haulm of strong upright growth, about 2 feet in length; stem, pale green, tinged with purple; leaflets, small, green, somewhat pointed, green; flowers, purple; berries, numerous, very large; tubers, medium-sized, half-round, frequently a little flattened, with a blunt end; eyes, a little sunken; skin, rough, but sometimes smooth, pale straw; flesh, white, firm. A very excellent even-cropping Potato. Mid-season.

§ 3. Round.

Regent (syn. York Regent, Mitchell's Prolific, Early Oxford, Pink Regent, Rintoul's White Don, Scotch Don, Rusty Coat, Rough Sket).—Haulm, moderately robust, spreading, from 2 to 3 feet in length; stem, pale green; leaflets, small, rugose, green; flowers, scarce, pale blue, seldom producing berries; tubers, round, generally of even medium size, sometimes large, long, flat, and coarse; eyes, a little sunken; skin, rough, pale straw; flesh, white, firm. Excellent quality. Productive. Mid-season.

Dalmahoy (syn. Goldfinder).—In haulm and general growth not distinguishable from Regent; ripens off earlier, and has the habit of showing the tubers a little more on to the surface of the ground; tubers, of even medium size, generally of more even and regular form than those of Regent, but of very similar character. A very productive excellent Potato for general use.

Walker's Early.—Like a strong Regent, but having the tubers much smoother in the skin and with deeper eyes than Regent.

Early Prince.—Haulm, &c., same character as Regent, but ripens much earlier; tubers, large; eyes, rather deep; skin, smooth, like Walker's Early. Second early.

Early Shaw.—Haulm, &c., of somewhat slender Regent character growth, and ripens off earlier; flowers, sterile; tubers, medium size, roundish, frequently half long and broad; eyes, large or wide, a little sunken; skin, smooth, pale straw-coloured; flesh, pale straw-coloured. Average cropper. Second early.

East Somerset Champion.—Haulm moderately robust, of the same character, but stem slightly coloured; tubers, very large, broad, of somewhat irregular form, being blunt at the crown and hollowed at the stalk; eyes, small, rather sunken; skin, a little rough, pale straw-coloured; flesh, pale straw, rather close. A very heavy cropper. Ripens same time as Regent, but is in best condition for use late in spring.

Early Perfection.—Haulm, &c., of somewhat slender Regent character of growth, about 18 inches in length; leaflets, rather broad, flat; flowers, pale blue, sterile; tubers, below medium size, roundish, but frequently long; surface, very even and regular; eyes, very few and full; skin, clear, pale straw, a little rough; flesh, pale straw. Light cropper. Early.

Early Union.—Haulm, rather slender, of the character of the Kentish Ashleaf, about 1½ feet in length; flowers, pale lavender, sterile; tubers, medium size, round, of even regular form, a little flattened at the crown and hollowed at the stalk; eyes, few, a little sunken, nearly all situate at the crown; skin, clear pale straw, a little rough; flesh, pale straw. A good cropper. Very nice clean-looking Potato. Early.

Rector of Woodstock.—Haulm, rather slender, spreading, from 2 to 2½ feet in length; stem, slightly coloured purple; leaflets, small, rugose, green; flowers, bluish, succeeded by berries; tubers, rather below medium size, of roundish form, frequently a little flattened at the crown; eyes, small, mostly situate at the crown; skin, smooth, clear, pale straw; flesh, pale straw, very firm. Excellent quality. Moderate cropper. Early. A very pretty Potato. Previously certificated.

Fenn's Early Market.—Haulm, slender, resembling the Ashleaf Kidney, about 12 inches long; stem, green; leaflets, small, curled, green; sterile; tubers, medium-sized, of roundish form, sometimes a little broad and elongated, and hollowed at the crown; eyes, slightly sunken; skin, a little rough, very clear, pale straw; flesh, pale straw. Excellent quality. A very clean, handsome-looking Potato, and a good cropper. First early. First-class certificate.

Bonne Wilhelmine.—Haulm, rather slender, spreading, about 2 feet in length; stem, a little coloured; leaflets, rather broad, rugose, pale green; flowers, pale blue, fertile; tubers, below medium size, half round, even form; eyes, few and full; skin, smooth, clear, pale straw-coloured; flesh, pale straw-coloured. A moderate cropper. Second early.

Seedling No. 1.—Haulm, of weak erect growth, about 12 inches in length; stem, green; leaflets, small, rugose, green; tubers, small, roundish; eyes, few, full; skin, a little rough, pale straw; flesh, pale straw. Light cropper. Second early.

Prince's Favourite.—Haulm, &c., slender, of the character of the Kentish Ashleaf, about 18 inches long; tubers, very small, round; eyes, few, a little sunken; skin, clear, pale smooth; flesh, pale straw. Worthless. Second early.

Paxton's Wonder.—Haulm, moderately vigorous, about 1½ feet in length; stem, green; leaflets, broad, pale green, like Lapstone, but rugose; sterile; tubers, small, round, even, and regular; eyes, few, full; skin, smooth, clear; flesh, pale straw. Small cropper. Early, but too small.

The Bloomer.—Haulm, slender, very spreading, from 12 to 16 inches long; stem, green; leaflets, very much curled, pale green; flowers, pale, fertile; tubers, small, round, of even regular form; eyes, full; skin, clear, smooth; flesh, pale straw-coloured. Small cropper. Early. Too small.

Pritchard's Seedling.—Haulm, small, of erect growth, about 12 inches long; stem, green; leaflets, broad, deep green, rugose; flowers, pale, fertile; tubers, medium-sized, half round, even form; eyes, few, full; skin, smooth, pale straw; flesh, pale, firm. Light cropper. Mid-season.

Royal Danish.—Haulm, small, of erect growth, from 18 inches to 2 feet long; stem, a little coloured purple; leaflets, small, much pointed, rugose, bright green; tubers, below medium size, half round, a little elongated; eyes, sunken; skin, smooth, pale; flesh, pale, yellow, soft. Light cropper. General season. Too small, worthless.

Onwards.—Habit, same as Kentish Ashleaf, with somewhat darker and more rugose leaflets; flowers, sterile; tubers, very small, flat, round, irregular; skin, pale straw-coloured; flesh, pale. Early. Too small. Worthless.

No. 2, White-blossomed.—Haulm, robust, but prostrate, about 2 feet long, not branched; stem, of a purplish tinge; leaflets, very broad, rugose, green; flowers, white, sterile; tubers, large, broad, flat, coarse, and uneven; eyes, prominent; skin, smooth, pale, straw-coloured; flesh, white, rather soft. A moderate cropper. Second early.

Series II.—Skin Red.

§ 1. Long or Kidney-shaped.

Early Sovereign.—Haulm, of compact growth, about 12 inches long, ripens off early; stem, pale, green; leaflets, very large, broad; flowers, rare; tubers, average size, of a long, narrow, cylindrical form, slightly tapering; eyes, scattered over the entire surface, but not too numerous, a little sunken; skin, smooth, of a pale rose colour; flesh, white. A good average cropper. Early.

American Late Rose (syn. American Pale Rose).—Haulm, of free vigorous growth, about 2 feet long; stem, pale green; leaflets, large, broad, very pale green; flowers, white, generally sterile; tubers, very large, long, cylindrical, from 7 to 10 inches, and generally a little flattened; eyes, not numerous, but scattered nearly over the entire surface, a little sunken, of a deep rose colour; skin, smooth, pale rosy-pink, very pretty; flesh, white and floury. Excellent quality. A most enormous cropper, from eight to ten large tubers being produced at a single stool, and frequently much more, and these tubers often weighing over a pound each. Second early. First-class certificate.

American Early Rose.—Haulm and habit of plant exactly resembling the Pale or Late Rose; ripens off earlier, and is not so tall in stem or so productive; the tubers, also, are smaller, more kidney-shaped, and of a more uniform pink or rose colour. Much inferior to the Late Rose.

Extra Early Vermont.—Haulm and habit of plant similar to Early Rose, but only about 12 inches long, ripens off very early; tubers, large, long, cylindrical, somewhat flattened, very similar in all characters to Late Rose, but is ripe some ten days earlier; flesh, white and floury. Very excellent quality. Average cropper. Early. First-class certificate.

Belvoir Kidney (syn. Taylor's Kidney, Rognon Rose).—Haulm, rather slender and straggling, about 2 feet in length; stem, tinged red; leaflets, rather small, dark green, rugose; flowers, white, sparingly fertile; tubers, average size, long, flat, regular kidney shape; eyes, very few and small; skin, smooth, dull pink; flesh, yellow. Handsome in appearance. Average cropper. Mid-season.

Wonderful Red Kidney.—Haulm, rather slender, very much in character of Kentish Ashleaf, from 12 to 18 inches long; leaflets, small, rugose, having a reddish tinge; tubers, rather small, but neat in form; eyes, few, full; skin, smooth, pale red; flesh, yellow. A great cropper, but the greater portion are very small and worthless. Early.

Pousse Debout.—Haulm, vigorous, of compact growth, about 2 feet in length; stem, reddish; leaflets, broad, green; flowers, white, fertile; tubers, small, long, narrow, tapering, rounded kidney; eyes, full, on raised knobs; skin, smooth, pale red; flesh, pale, firm. A great cropper, but the greater portion are quite small and worthless. Mid-season.

Saucisse.—Haulm, rather slender, but growing to nearly 4 feet in length and branching; stem, reddish; leaflets, small, rugose, green; tubers, average size, short, broad, flat, rather irregular in form; eyes, full, even; skin, smooth, deep rose; flesh, yellow, hard, frequently streaked with red. A great cropper, but very inferior. General season.

French Red.—Haulm, very vigorous, branching, from 3 to 3½ feet in length, grows late; stem, reddish; leaflets, small, rugose, deep green; tubers, average size, but very irregular in form, some being round, others long, cylindrical; eyes, numerous, scattered over the entire surface; skin, rough, red; flesh, yellow. A great cropper, but the greater portion very small and worthless. Late.

Cottager's Red.—Haulm, moderately vigorous, straggling, about 4 feet in length; stem, reddish; leaflets, small, rugose, green; tubers, average size, of rather irregular form, some being long, broad, and flat, whilst others are nearly round; eyes, scattered, a little sunken; skin, rough, bright red; flesh, yellow. A somewhat irregular cropping Potato.

Rosee de Conflans.—Haulm, vigorous, of compact growth, from 3 to 3½ feet in length; stem, reddish; leaflets, broad, green; flowers, white, fertile; tubers, average size, very long, narrow, cylindrical, twisted, and tapering, with knobs; eyes, full, scattered; skin, smooth, dull red; flesh, yellow, streaked with red. A very peculiar-looking, but altogether worthless, variety.

Prince Imperial.—Haulm, moderately robust, spreading, from 2 to 2½ feet in length; stem, reddish; leaflets, small, pale green, rugose; flowers, white, fertile; tubers, average size, of rather irregular form, a long pointed kidney, frequently twisted like a crab's claw; eyes, few, full; skin, rough, reddish-purple; flesh, yellow. Moderate cropper. General season. Worthless.

Vitelotte.—Haulm, very robust and gross, about 2½ feet in length, and grows late; stem, green, with a reddish tint; leaflets, rather broad, rugose, green, with reddish veining; flowers, white, fertile; tubers, small, long, narrow, cylindrical, and pointed or tapering; eyes, deep, covering nearly the entire surface, so that it appears to be nearly all eyes; skin, smooth, reddish-purple; flesh, white, streaked with red. A very singular variety, but entirely worthless. Fit to be grown only as a curiosity.

Bountiful.—Haulm, rather slender, spreading, from 1½ to 2 feet in length; ripens off early; stem, reddish; leaflets, small, green, rugose; flowers, white, fertile; tubers, of true kidney shape, medium size, short, even, and of very regular form; eyes, few, full, giving it a very smooth, even surface; skin, smooth, reddish-purple; flesh, pale, firm. A very neat, handsome Potato, and a fair cropper. Second early.

Rognon Violet.—Haulm, rather slender and straggling, about 3½ feet in length; stem, purple; leaflets, small, rugose, dark green; flowers, white, fertile; tubers, large, long, flat, kidney shape, of even regular form; eyes, full, scattered, but not numerous; skin, smooth, of a reddish purple; flesh, pale straw, firm. A fair average cropper. Late.

Callo.—Whole plant, somewhat of the Lapstone character; haulm, moderately robust, about 2 feet in length; stem, pale green, tinged red; leaflets, broad, pale green, quite smooth; tubers, medium size, long, cylindrical, regular form; eyes, wide, scattered, of a dark purple; skin, smooth, reddish-purple; flesh, white, firm. A heavy-cropping Potato. Late.

California Kidney.—Haulm, slender, about 1½ feet in length, ripens off early; stem, pale green; leaflets, broad, green, rugose, of the Regent type; flowers, few, pale blue, sterile; tubers, large, long, cylindrical; eyes, numerous, deeply-placed, and scattered over entire surface, giving it a rough, uneven appearance; skin, smooth, bright red, occasionally flaked with white; flesh, pale straw, hard, coarse. Moderate cropper. Early.

Truffe d'Aout.—Plant of vigorous compact growth, of the appearance of Myatt's Prolific, about 1½ feet in length; flowers, pale, fertile; tuber, below medium size, of short, oblong shape; eyes, deep, numerous, scattered; skin, a little rough, dull red; flesh, pale yellow, streaked with red. A moderate cropper, but a very bad, worthless sort. Late.

§ 2. Round.

Red Emperor.—Haulm, slender, straggling, and spreading, about 4 feet in length; stem, tinged with red; leaflets, small, pointed, rugose,

light green; flowers, light blue, sparingly fertile; tubers, medium-sized, round, somewhat flattened, very even and regular; eyes, full and few, a bright red; skin, generally smooth, of a clear light red, sometimes with a flake of white; flesh, pale straw, firm. Excellent quality. A very handsome Potato. Average cropper. Second early. It is somewhat tender and subject to disease.

Combe Hays.—Very similar to Red Emperor, but somewhat later. Bears berries in abundance, and the tubers have somewhat rougher skin.

English Rose.—Haulm and foliage, similar to Kentish Ashleaf, about 12 inches high, ripens off early; flowers, reddish-white; tubers, small, round, with a smooth even surface; eyes, full, small; skin, smooth, pale red; flesh, white, streaked with pink. Early, but too small, and of good quality.

King of the Earlies.—Haulm, of compact growth, about 12 inches long, ripens off very early; stem, pale green; leaflets, very large, broad, of a very pale green; flowers, very rare; tubers, average size, half round, flat; eyes, a little sunken; skin, smooth, of a faint rosy-pink colour; flesh, white. Moderate cropper. Early.

Rouge de Strasbourg.—Haulm, very robust, much branched, erect and compact growth, about 3 feet in length, grows very late; stem, purplish; leaflets, rather broad, dark green-shaded purple; flowers, purplish-white, seldom fertile; tubers, medium size, long, rounded, irregular, coarse; eyes, deep, numerous, scattered over entire surface; skin, smooth, deep red; flesh, white, close-grained. Bad. A coarse heavy-cropping, late Potato.

Red Regent (syn. De Zelande).—Haulm, very robust, much branched, of erect and compact growth, from 3 to 3½ feet in length; stem, reddish; leaflets, rather broad, light green; flowers, white, seldom fertile; tubers, large, exactly resembling the Regents; skin, rough, deep red; flesh, pale. A heavy-cropping late Potato, suited for field culture.

Wood's Scarlet Prolific.—Haulm, moderately robust, of erect compact growth, about 2 feet in length, grows very late; stem, light green; leaflets, pale green, rugose; flowers, light purplish, fertile; tubers, very large, long, flattened, even, and regular, nearly all of the same size, at a stool, and are borne close to the haulm; eyes, deep, scattered over surface; skin, rough, reddish-purple; flesh, white, occasionally streaked with red. A very handsome late Potato, and a great cropper. Second-class quality.

Webb's Red Blossom.—Haulm, robust, erect, but much branched, about 2½ feet in length, grows very late; stem, green; leaflets, broad, rugose, green; flowers, white, sterile; tubers, long, flat, very irregular, some being large and handsome, but the greater portion small; eyes, deep, scattered; skin, rough, bright, purplish-red; flesh, pale straw, streaked with red. Very coarse-growing. A late cropper. Late.

Vermont Beauty (syn. Brownell's Beauty).—Haulm, small, of same character as Early Rose, about 1½ feet in length, ripens off early; leaflets, broad, pale green; flowers, purplish-white; tubers, very large, long, broad, and flattened, very uniform in character, and borne close to the haulm, about five or six to each stool, with seldom any small ones; eyes, wide open, scattered, but not numerous; skin, rough, of a dull brick-red; flesh, white, floury. Excellent quality. A remarkable handsome second-early red Potato, and a heavy cropper. First-class certificate.

Red-skinned Flour-ball (syn. Improved Red-skinned Flour-ball, Barkshire's Red-skinned Flour-ball, Red Peach-blossom, Boston Red, American Red, Kentish Red).—Haulm, strong and robust, frequently much branched, from 3 to 3½ feet in length; stem, pale, with a reddish tinge; leaflets, medium-sized, flat, pointed, rugose, pale green; flowers, shaded lilac or lavender, produced in great abundance, very seldom fertile; tubers very large, round, but frequently a little flattened, often of very coarse and irregular form, one stool producing half a dozen some well-formed tubers, whilst another produces them of various shapes and sizes; eyes, mostly situate at the crown, which is a little sunken, and it is also a little hollowed at the stalk; skin, rough, of a light red colour, but on many of the malformed tubers quite smooth, and of a deep red; flesh, white, and, for a late Potato, of excellent quality. It is a large and heavy cropper. General season.

White Peach-blossom.—Haulm, of strong and compact growth, much branched, about 3 feet in length; stem, green; leaflets, broad, pointed, smooth, green; flowers, rosy-purple, fertile; tubers, very large, round, coarse in appearance; eyes, few, but deep, of a bright rose-colour; skin, rough, of a pale pink colour; flesh, white, firm. A very heavy-cropping, but coarse, late Potato.

Series III.—Skin Purple or Blue.

Paterson's Blue (syn. Morayshire Blue).—Haulm, robust, of compact, rather erect growth, about 3 feet in length; stem, reddish; leaflets, small, rugose, deep green; flowers, purplish-white, occasionally fertile; tubers, large, round, flattened, frequently elongated, rather coarse in appearance; eyes, deep, scattered; skin, smooth, reddish-purple; flesh, white, very firm. Moderate cropper. Late.

Purple Regent.—Plant, habit of true Regent, but having a reddish stem, and the leaflets of a somewhat deeper green; flowers, purplish-white, seldom fertile; tubers, medium-sized, half long, a little flattened, seldom uneven, but rather coarse in appearance; eyes, small, scattered; skin, smooth, reddish-purple; flesh, white, firm. A very poor crop and a generally bad sample. General season.

Compton Surprise.—Haulm, very robust and gross, from 2½ feet in length, ripens off early; stem, green, tinged with red; leaflets,

very large, broad, pale green; flowers, white, sterile; tubers, large, long, flattened, coarse in appearance; eyes, numerous, very deep, scattered over entire surface; skin, smooth, dark purple; flesh, white, firm. A moderate cropper. Mid-season. Rather coarse.

Scotch Blue (syn. Duncan's Seedling).—Haulm, moderately vigorous, about 2 feet in length, ripens off early; stem, reddish; leaflets, large, broad, rather pale green; flowers, none; tubers, medium-sized, oblong, flattened, frequently much elongated and cylindrical, with a smooth, even outline; eyes, wide open; skin, smooth, dark violet; flesh, white, firm. Very handsome, but a very uncertain cropper. Mid-season.

Summer Hill Seedling.—Haulm, very strong and robust, from 2½ to 3 feet in length; stem, having a reddish tinge; leaflets, large, broad, pale, with a tinge of red; flowers, bluish, fertile; tubers, medium size, oblong, flattened, of a finely-rounded, even outline; eyes, small, full; skin, smooth, dark purple; flesh, white, firm. A very handsome Potato, and a fair average cropper. Late.

Black Jack (syn. Black Bob, Black Nigger).—Haulm, robust, straggling, and somewhat branching, about 3½ feet in length; stem, reddish-purple; leaflets, small, rugose, deep green; flowers, blue, seldom fertile; tubers, medium-sized, round; eyes, deep; skin, smooth, very dark purple, almost black; flesh, dark mottled purple and white. A poor cropping and utterly useless late Potato. Fit only to be grown as a curiosity.

Series IV.—Skin Streaked or Flaked.

Gleason's Late (syn. Hundredfold Fluke).—Haulm, robust, branching, about 2½ feet in length; stem, of a reddish tinge; leaflets, flat, pointed, green, with coloured veins; flowers, purple, generally sterile; tubers, large, generally broad, flat, like a Fluke, but frequently of very irregular form, as if two or three were joined together; eyes, few, full; skin, smooth, very pale, with large patches of rosy-purple, giving it a very singular piebald appearance; flesh, white, rather hard. A good average cropper. Late. Very handsome.

Painted Lady.—Haulm, strong and robust, of the Fluke character, but dies off earlier, from 2½ to 3 feet long; stem, green; leaflets, small, rugose, green, like Regents; flowers, rosy-red, fertile; tubers, very irregular in size and form, but chiefly small, of a long, flat kidney shape; eyes, few; skin, on some tubers rough, and on others smooth; some pure pale straw-coloured, others streaked and splashed with deep rosy-purple; flesh, pale, firm. A light cropper, the greater portion being small. Late. Worthless.

Willard (syn., Belgian Wax Ball).—Haulm, moderately strong, erect, from 1 to 1½ feet in length; stem, pale green; leaflets, broad, rugose, pale green; flowers, very rare; tubers, large, long, cylindrical, inclining to conical, generally of even and regular form; eyes wide, even with surface, scattered; skin, rough, bright red, much flaked with white around the eyes; flesh, white, hard, and inferior. A very handsome Potato. Moderate cropper. Second early.

Red Breadfruit.—Haulm, slender, of rather compact growth, about 2 feet in length; stem, green; leaflets, small, rugose, green, of the Regent character; flowers, pale blue, fertile; tubers, rather below medium size, round, somewhat hollowed at the crown and also at the stalk; eyes, full; skin, smooth, reddish-purple, flaked with white; flesh, pale straw-coloured. A moderate cropper. Second early.

Pink-eyed Rusty-coat.—Haulm of strong but straggling growth, from 3 to 3½ feet in length; stem, purplish; leaflets, small, pointed, rugose, green; flowers, deep rosy-purple, borne in great abundance, generally sterile; tubers, large, of very irregular round form, and coarse; eyes, wide open, of a rosy-red colour; skin, smooth, white, flaked with pink; flesh, white, firm. A heavy-cropping, but rather coarse Potato. General season.

Blanchard (syn., Fillpeck—Peake).—Haulm, slender, spreading, from 12 to 18 inches in length; stem, dark purple; leaflets, small, rugose, dark green; flowers, light or pale blue, fertile; tubers, medium, round, flattened at the crown, even and regular sample; eyes, nearly all situate at crown, full, of a dark purple colour; skin, smooth, pale straw, flaked with purple; flesh, yellow, firm. A clean, pleasant-looking Potato. Good quality. Moderate cropper. Second early.

Rintoul's Striped Don.—Haulm and habit of a robust-growing Regent; tubers, very large, roundish; eyes deeply set, of a dark purple colour; skin, rough, pale straw, streaked and flaked with purple; flesh, pale, firm. A handsome and excellent great-cropping Potato. Second early.

Fortyfold.—Haulm and habit of Regent, but a little more slender; tubers, scarcely medium size, round; eyes, few, a little sunken; skin, light, reddish purple, flaked with white; flesh, white, firm. Excellent quality. Moderate cropping. Second early.

Free-bearer (syn., Benson's Round).—Haulm and habit of a strong-growing Regent, exposes the tubers on to the surface of the ground; tubers, very large, rather coarse, long, rounded form, like Striped Don; eyes, large, deep; skin, rough, dark purple, flaked with white; flesh, white, firm. A heavy-cropping Potato, and good for general crop field culture.

Oxfordshire Kidney Potato.—Through the kindness of Messrs. Sutton & Sons, I have been enabled to try this, which may, with truth, be called the Prince of Potatoes. The skin is rough—as rough can be, which alone, according to my way of thinking, forms a chief point. The tubers are kidney-shaped, and their size the happy medium of what Potatoes should be. They are, in my use, free from disease, in consequence of their strong woody-like growth. From sets 2 oz. in weight, the produce was sixty in number, fair sizeable potatoes, weighing 11 lbs. Lastly, the quality is all that can be wished.—R. ALBERT, *Burghley*.

WORK FOR THE WEEK.

PRIVATE GARDENS.

The Flower Garden.—In re-arranging flower-gardens, hardy evergreen shrubs may be employed with the best results; for, in the working out of parterre patterns, judiciously disposed groups with graceful outlines, associated with bedding plants, are more effective and desirable than many of the tender subjects now so freely used for such purposes, necessitating, as they do, the employment of unusual care and fertility of expedients on the part of the cultivator, and often, after all, producing but a small amount of success. One of the most important points in connection with flower-garden operations, at this season, is preparation of the beds and the securing of proper composts. Where beds are not planted with spring-flowering things, advantage should be taken of the fallow, so to speak, to which they are subjected, to have them deeply worked up and prepared for planting. Upon poor soils, too little attention is often paid to our flower-beds, which are kept under crop year after year, without taking into consideration that the ground is becoming annually poorer. Flower-beds, to be perfectly successful, must be treated according to the crop which they are intended to carry. Some things, as for example, Abutilons, Aralias, Cannas, Ferdinandas, Ricinus, Solanums, Wigandias, &c., require a large amount of manure to give them nobility of aspect and perfect leaf development. In preparing beds for these, especially in cold wet localities, it will be advantageous to place the soil on brick rubble, which will secure good drainage, and tend to raise the temperature of the soil a few degrees higher than it otherwise would be. The compost should be used in rather a rough state in order to promote healthy development by gradual decomposition. Hardy Clematises grown as bedding plants should now have attention; their blooming season may be considerably prolonged by pruning them at three different periods, viz., in autumn, mid-winter, and early in spring. Cut them back now to the ground, and surface-dress with rich rotten manure. This is especially necessary in order to ensure continuity of bloom. Fill up all vacancies which may now occur among spring-blooming plants, and pay every attention to securing neatness and order. If the plan for the bedding out of the flower-garden has not yet been determined upon, it should now receive immediate attention, in order that some idea may be formed as to what quantities of different subjects must be secured by means of propagation.

Shrubberies.—This is a good time to re-plant and re-arrange masses of the better kinds of Rhododendrons, which, when grouped with taste, are gorgeous in the extreme. Their hardiness and luxuriant deep green foliage render them desirable at all seasons; but many, nevertheless, are deterred from growing them from an impression that they do not succeed without peat. No doubt sandy peat is the best soil for them when procurable; but, where it cannot be had, they will not only grow, but luxuriate in a sandy fibry loam. In preparing positions for Rhododendrons resting upon calcareous matter, it is imperative to success that the whole of the soil in the beds should be above the ground level, otherwise the drainage from the surrounding grounds will penetrate the beds and destroy the plants. In planting, hardy Azaleas must not be overlooked, their brilliancy of flower and delightful fragrance rendering them most desirable. They may be grown in masses by themselves, or interspersed with Rhododendrons, or used promiscuously in mixed shrubberies. Kalmias are not so much planted as they deserve to be, for they are amongst the most elegant of plants grown, their charming delicate blossoms and dark glossy foliage contrasting admirably with most kinds of vegetation with which they may be associated. They grow freely in low situations; and, moreover, the Kalmia is one of the few plants that game will not molest. Attend to previous directions as to planting and pruning. Common Laurels should be cut down; but under no circumstances should specimen Portugal Laurels be pruned now, as the searing winds we often experience after this time disfigure the foliage to such an extent as to render it unsightly for months, which late pruning will, in a great measure, obviate.

Conservatories.—These are now gay with Dutch bulbs, Cyclamens, Chinese Primroses, Cinerarias, Camellias, Azaleas, forced shrubs, Epacrises, Heaths, Acacias, and a few other plants. The pretty water-plant, Aponogeton distachyon, is in full flower, both in the coolest part of the greenhouse and also in cold frames; it is so easily grown, too, that a large inverted bell-glass, or flower-pot or pan with all holes stopped up, forms a sufficient home for it. Pot, cut back, and start into growth, in the warmest corner of the greenhouse, some Fuchsias and Lemon-scented Verbenas. Some Cineraria seed may be sown in gentle heat to furnish flowers late in autumn; and young Cyclamens may be pricked off into pots or pans. Mignonette should now be sown in pots for early blooming; plants of it that are up should be thinned, and Tree-Mignonette should be trained and

tied into proper form. Pelargoniums may be shifted and placed in a warm corner of the greenhouse. Tropæolums should be trained twice a week, and, as soon as their flower-buds are well set, weak manure-water may be freely given to them. Remove dead foliage from Carnations in pots, and stir and top-dress the soil. Divide and re-pot plants of *Isolepis gracilis*, and place them for a time in a moist heat. Selaginellas may also be separated, and potted in a mixture of loam, peat, and leaf-mould in equal proportions, with a good admixture of sharp sand. Borders of these little plants may also be renovated. If a good stock of seedling Ferns is at hand, one or two of a sort may be stuck into a pot containing Hyacinths and Tulips; they hide the surface soil, and render the pots more pleasing in appearance. Greenhouse Ferns should be kept as dormant as possible yet, especially such as are deciduous, and also hardy Ferns in pots, but a dust-dry condition is injurious.

Indoor Fruit and Forcing Department.—If the weather be fine, push down the lights of Pine pits about half an inch for two or three hours at mid-day. Cover frames containing Pines with mats at night. To such as are planted out in frames give no water if the heat is kept up by means of fermenting material. Watch carefully fire-heated pits or houses. For Vines coming into flower, maintain a night temperature of 65°. Admit a little fresh air as long throughout the day as is practicable when the blossoms have expanded, keeping up the temperature by means of fire-heat at the same time. If the air comes heated into the house by being made to travel along or over hot-water pipes, so much the better. Syringe Vines breaking into leaf, and, if possible, maintain the desired amount of heat by fermenting material. Remove loose bark from late Vine rods, and wash and paint them with some insect-destroying mixture. Syringe daily Peach trees whose fruit has set. Ventilate a little, day and night, houses in which plants are in flower, and give fire-heat at the same time. Prune the latest trees, and shut up another house for succession. If French Beans are not already in Vineries or pits, place them along the narrow front shelf in Pineries. Place a few sprays of Birch twigs in each pot, and run a cord along next the path, so as to prevent the twigs or plants coming in contact with the clothes of the workmen. Syringe them frequently and water them abundantly. Sow Mustard and Cress in boxes according to demand, and keep the boxes in early Vineries or Peach-houses. Introduce also some roots of Mint and Tarragon. Keep up a succession of Rhubarb, Seakale, Endive, Chicory, and Dandelion, in the Mushroom-house, or in any other place where a temperature of 55° can be maintained. If Seakale be forced too slowly, it becomes stringy. Asparagus is best forced in hot-beds. If a large quantity of roots has been lifted at once, lay them in a heap, but not so thickly as to cause fermentation, and cover them over with a mat. It is better, however, to lay them into the soil quite thickly, and to lift as required. Construct hot-beds for Potatoes. Start the tubers in some of the forcing-houses, and after they have pushed into growth an inch or two in length, plant them out in the frames. Sow some Radish seed over the soil, the young Radishes from which will be ready for use before they become an obstruction to the Potato crop. Prepare hot-beds consisting of two parts of leaves, and one of litter for Turnips, Cauliflowers, Lettuces, Celery, Onions, &c. Brisk hot-beds are also necessary for Tomatoes, Melons, Cucumbers, &c.

ASHANTEE VEGETATION.

THIS is described by the special correspondent of the *Standard* as follows:—"Thicker and higher grew the bush as we neared Akroful, on our way to Coomassie. One could see by the aspects of many of the trees that winter had begun. Almost all the gigantic Cotton trees, towering from 200 to 250 feet on their perfectly straight, round, even trunks, were now leafless, looking like the skeletons of some giants of primeval vegetation raised above a sea of foliage below them. Some of the other kinds of trees had also begun to shed their leaves, and the road was at times thick with them. There is another forest giant which almost, although not quite, rivals the Cotton tree. This the natives call the "Wa-wa." It is similar in growth and character to the Cotton tree, but the latter has a small feathery foliage like that of the Acacia. The Wa-wa has a leaf resembling, as far as I could judge, that of the Beech. The varieties of trees in this tropical bush are immense, but, innumerable as the trees were, there were two or three species which especially struck me, and of these I saw two specimens of one which was a very striking one. It was 50 or 60 feet in height, and bare of branches for more than half its height from the ground; it had shed its foliage, and was as thick as a Pear tree in spring, with a greyish-pink blossom. One of the trees hung over the road, and some of the blossoms had fallen. They somewhat resembled in form those of a *Salvia*. Another of the trees which struck me particularly was a very large one, with a dark green foliage, somewhat resembling that of the evergreen Ash. This

tree was in seed, and the effect was singular and picturesque; the seeds hung in bright green clusters of some 2 feet long; they were flat, and somewhat oval in form, and arranged with curious regularity, having the aspect, at a short distance, of huge clusters of Grapes. Both these trees were so striking that they could not have escaped my observation had they grown within eyesight of the road, and yet I only saw the number I have named along the whole line from Cape Coast to this place. Of flowers I saw a few white Lilies, a few pink flowers of some bulbous-rooted plant, the stripes of yellow occasionally upon an Acacia, and a climbing plant like that of the Dog Rose, and some yellow flowers in some of the old village churches. With the exception of a few *Convolvuli* and some small ground-like creepers these were nearly all the flowers that I have seen since leaving the open bush. As to the luxuriance of the foliage of these tropical jungles, the pen fails altogether to convey any impression. Fifty paintings by the hand of a master might give a fair idea of the tangle and confusion, the glorious variety, the exquisite beauty, the grand magnificence, the brightness of some spots, and weird gloom of others; but volumes of written matter would fail to give any adequate impression of the tropical bush and forest. Everywhere it was beautiful; but some little bits struck me as especially lovely. There was one glade where a stream ran across the road. Upon one side of this stream the sun shone brightly, upon the other was a cool deep shade. A great clump of *Bambusa* grew on either side of the road, over which these drooping stems met, forming a magnificent arch of feathery foliage of fully eight feet span. Behind the forest closed thickly in, turning everything beyond the arch into deep shade, with just a stream or two of sunlight falling upon the road. Such a scene, entitled "The Bamboo Palace of the Wood Spirits," would make the fortune of an extravagant ganza, and was, I think, without exception, the most lovely little bit of scenery I ever saw. Between Akroful and Dunquah the foliage was more tropical—according to the received idea upon the subject in its character than it was beyond. Plantains, Palms, and *Bambusa* formed the larger portion of the bush, but beyond Dunquah these became more rare, the forest grew denser, the interlacing of creepers and parasites thicker, and the undergrowth proportionately less. Here, were it not for the giant Cotton trees and the *Wa-wa*'s and the broad leaves of the climbers, it would not be difficult to imagine oneself in some forest at home, where the forest is a minor, the estate in Chancery, and the woods allowed to take themselves uncared for.

The Improvements in St. Paul's Churchyard.—An important improvement in St. Paul's Churchyard was formally dedicated the other day, by the Dean and Chapter and the Lord Mayor, to the use of the public. The space thrown open comprises an area of 7,000 square feet. This space has been purchased from the Dean and Chapter by the Corporation of the City of London for the sum of £15,000. Of this sum, however, the Dean and Chapter had expended about £6,000 in the work of carrying out the improvements. The roadway has been enlarged by above 7,000 feet, and a space, semi-elliptical in form, has also been flagged in front of the Cathedral inclosing upwards of 15,000 feet. This ground will remain the property of the Dean and Chapter, but foot passengers will have access to it. Upon the occasion of important services in the Cathedral, this will be temporarily inclosed by barriers fixed to granite posts which mark the boundary.

The So-called New Substitute for Coal.—This is by no means new. About fifteen years ago my coal supply running short I hit on the following expedient:—I took half slack coal and half mud (mud is best where it can be procured; if not firm, sub-soil will answer), I added a small quantity of soda, mixed all together to the consistency of paste, then divided and rolled into balls of sizes to suit grate, and allowed them to dry; this is all that is required. A few of these balls will last the whole day, and preserve a steadier temperature than coal itself.—M. PIGOTT, *The Gardens, Castle Hyde, Farnham*.

A new mode of Artificial Fertilisation.—We learn that the process, indicated by M. Hooibrenk, of Vienna, for facilitating the fertilisation of plants, has proved successful in the Botanical Garden there. The process consists simply in touching the end of the pistil—that is, the stigma—in a flower, with a pencil dipped in honey, or, better, in honey having mixed with it some pollen of the plant operated upon. A *Hibiscus mexicanus*, which had not yielded fruit, having undergone this treatment, produced quite a large quantity of good seeds. With several fruit-trees the process also succeeded. Further, after operating on certain branches of trees which did not yield fruit, it was found that fruit formed on these, while the branches left in the natural state gave none. The effect, if real, may be explained by supposing that the honey retains the pollen grains on the stigma, and thus favours the formation of a pollen tube, which is indispensable to the fertilisation.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but

THE ART ITSELF IS NATURE."—*Shakespeare.*

GARDEN INSECTS AND THEIR DESTRUCTION.

(RED SPIDER.)

If the size of this insect was proportionate to the damage it does to plant-life, it would be much more formidable in appearance than it is, but, being exceedingly small, it frequently escapes detection, until the plants upon which it makes its appearance have sustained serious injury. Great numbers of cultivated plants, especially such as are grown under glass, suffer from its ravages; but such as have thin soft leaves, like Vines, Cucumbers, and Melons, are more subject to it than others. The living insects cannot exist in a low temperature, but their eggs are proof against the lowest temperature of our severest winters. The red spider has a great aversion to moisture in the atmosphere, and still more to its application directly overhead by the use of the syringe or garden engine, a fact which at once indicates the means most likely to prevent its appearance where water can be used plentifully without injury, in other respects, to the general health of the plants. In the stove, the fruit-bearing Banana, and the acid-juiced Croton, or Euphorbia, alike furnish food for it. Dipladenias, Hibiscus, Ixoras, Francisceas, Amaranthus, Palms, Ferns, Dracænas, together with quantities of other plants, are affected by it. Through the growing season, a plentiful and continuous application of water overhead with the syringe is necessary, and it frequently happens that this is insufficient to keep it down, unless used in quantities that will make the soil too wet, and, consequently, injurious to the roots of the plants. Where such is the case, for hard-wooded plants, a weak solution of "Fowler's Insecticide," 2 oz. to the gallon, will be found a very effectual remedy. In the autumn and winter seasons, when the usual afternoon syringing is discontinued, Red spider is frequently very troublesome, and any plant affected by it should receive a washing with the insecticide as often as it makes its appearance. In the stove, I do not advocate sulphuring the pipes, as there generally are numbers of plants that suffer from that practice: neither is the application of sulphur dusted over the plants safe in all cases, as it frequently causes quantities of the leaves to fall off. Orchids are not so often attacked by this insect as other plants. The humid atmosphere kept up in the houses devoted to them, keeping it in check; yet the introduction of an infected plant will sometimes cause a good deal of trouble amongst the thin-leaved species, such as Dendrobiums, Lycastes, Sobralias, Odontoglossums, and some Oncids; and, if a considerable number of plants are affected before it is discovered, it takes a serious amount of labour to eradicate it completely, as there is no method that can safely be employed, except sponging every leaf with clean water; this requires to be thoroughly done, going regularly over all affected plants without omitting a single leaf, and repeating the application until no trace of the insect can be found. Ferns are not often attacked by this insect, yet sometimes it appears on the fronds of tall Tree varieties, that happen to be near the roof glass, and in that case copious washings with the syringe are the best means to employ for eradicating it. Conservatory climbers, particularly such things as Mandevilla suaveolens, Kennedyas, &c., are very subject to spider, and it spreads from such plants apace over everything under them on which it can live. Persistent use of the syringe or garden engine, is all that can be done in such a case, except the application of sulphur to the pipes, in a way hereafter to be recommended for Vines. Some greenhouse plants are very subject to red spider, as, for instance, Fuchsias, Statice, Pleromas, Pimeleas, Chorozemas, as well as numerous soft-wooded plants; but a liberal use of the syringe, and, if this is found insufficient, "Fowler's Insecticide," 2 oz., to the gallon, will destroy it. There is one greenhouse plant which red spider seems to like better than almost all others, viz., the Glory Pea (*Clianthus puniceus*). Wherever this, or anything

that is similarly subject to this insect, is grown, they should be examined, during the growing season, every few weeks, for, if they are neglected, and the insect is permitted to thoroughly establish itself, it not only completely spoils the plants upon which it first makes its appearance, but spreads to any others standing near them. Pimeleas should be regularly syringed during the growing season every evening, getting well to the undersides of the leaves, for, if these plants ever get thoroughly infected with this insect, they never afterwards get into a free habit of growth. Even Heaths, if placed in contact with plants suffering from this pest, will be seriously damaged by it, if not discovered before it has got much hold of them. For any plant of slow growth, which retains its leaves naturally for years, it will at once be obvious that the destruction of its foliage is far more serious than in the case of deciduous plants, or such as are of quick growth, and consequently are enabled to recover from any injury of the kind. Plants grown for the beauty of their foliage, such, for instance, as Cordylines and Dracænas, if the leaves of these are injured by the ravages of insects, they can never be replaced, as, when once they get yellow, which they quickly do through the effects of this insect, they fall off prematurely.

On Vines.

To Vines red spider is extremely partial, and it does more harm to them than all other insects put together. Where it has established itself, during the season, as soon as the leaves are off, the Vines should be pruned, taken down, and the oldest outside bark removed (without stripping it too closely as is often done, and which does serious injury), getting well into any hiding places where the eggs are deposited, then paint the whole of the canes thoroughly, from the collar to the extreme point, with the usual dressing of water, clay, and a little soot, mixed to the consistency of thick paint, to which add 1 lb. of flowers of sulphur to each gallon. Scrub all the wood and iron-work thoroughly with soap and water, limewash all the brickwork. If there is an inside border, remove 2 inches of the surface soil, and add an equal amount of new material. When the house is again started, and until the Vines come into bloom, use plenty of moisture in the atmosphere, and syringe regularly overhead. Those who aim at high-class Grape-growing, with the berries as heavily covered with bloom as possible, generally cease syringing after the opening of the first bloom; but to the amateur, or those who have not had much experience, I would say, begin syringing again as soon as the berries are set, and continue to do so daily, until the fruit begins to colour; it will make the bloom thinner, and so far will injure the appearance of the fruit, but the chances are that the Vines will finish the crop better, without distressing them half so much as if the syringe had not been used after the flowering stage, for the spider is almost certain to make its appearance before the fruit is near ripe, if the syringe is not used. Hundreds of Vines that get into a bad condition have the evil laid to the charge of over-cropping, when the cause is due quite as much, or more, to the ravages of this insect. The most effectual means for its destruction is the application of sulphur to the pipes or flues, but if the house is flued, care must be taken that the sulphur is not laid on the flue too near the furnace, or the consequences may be most disastrous on account of the ignition of the sulphur. With hot-water pipes, this cannot occur. To one part fresh lime add two parts flowers of sulphur, and mix with as much water as will bring it to the consistency of thick paint. On a mild dull evening, if possible, get the water in the pipes as near boiling as can be, close the house and saturate the atmosphere, with water, then regularly paint the pipes over with the mixture. If the weather is dull, so as to require little or no air during the following day, so much the better. An almost general impression prevails that if sulphur is applied to the pipes before the berries are stoned, the skin will be injured. In the case of tender-skinned sorts, like Buckland Sweetwater or Foster's Seedling, if the bunches are near the pipes such will be the case, but Hamburgs, Muscats, Alicante, or Lady Downes, will not suffer. If the atmosphere is thoroughly saturated, the skin of the berries becomes coated over with the moisture, which appears to shield them from injury; but for the thorough destruction of the insect, and freedom from injury to the fruit, the above directions as to thorough

saturation of the atmosphere must be carried out in their entirety, and the operation must be repeated in the course of ten days, by which time any eggs that have been deposited will have come to life. I may here state that no insecticide can with safety be applied to Vines, except to the bare wood when at rest; any dressing after the berries are formed will disfigure them, and if applied in the late stages of growth, will leave unmistakeable evidence of its presence by tasting the fruit.

On Cucumbers and Melons.

Cucumbers are subject to red spider, but on them it can be kept under by the use of the syringe. Melons are especially subject to spider in the early stages of their growth, and whilst the fruit is swelling the syringe will keep it under; but when the fruit begins to ripen, necessitating a drier atmosphere, it is more difficult to manage. In houses or pits heated with flues or hot water, it can be treated as in the case of Vines; but in dung-pits or frames it is difficult to manage. During the ripening season, a close watch should be kept, so as to detect the insect as soon as it makes its appearance, carefully sponging the leaves thoroughly both on their upper and under surfaces.

On Peaches and Nectarines.

The Peach-house is one of its favourite haunts, if there is an insufficiency of water applied to the trees overhead; but where the syringe is used freely in the early stages of the growth of the fruit, it has not much chance of getting established. Neither should it be allowed to run riot over the trees after the fruit is gathered, as such has a most baneful influence upon their strength, causing the leaves to fall prematurely, and thereby destroying the vital power of the trees. Peaches and Nectarines on open walls are alike subject to this insect; but, here again, it is attributable to an insufficient use of the garden engine. The Peach, in its native habitat, is subject to a great amount of moisture, and an insufficiency of this at once renders it a prey to every insect that revels in a dry atmosphere. To keep red spider down, the Peach wall should have a good washing with the garden engine twice a week, from the time the trees go out of bloom to their commencing to ripen.

On Ordinary Hardy Fruits.

Fruit-trees, when removed, after they have got to a considerable size, or after root-pruning, more especially Apples, are frequently severely attacked by red spider to an extent that will seriously injure the fruit both in size and quality. Where the trees are of moderate size, and not in too great numbers, a good washing with Gishurst Compound—3 oz. to the gallon—as soon as the insect makes its appearance, together with the use of the garden engine once a week for a time afterwards, will effect its destruction. This is essential, as, if the insects are permitted to take their course, they will leave, each autumn, a brood of eggs that will regularly supply a numerous colony of the insects every spring. In the case of very large trees that are affected, or where they are numerous, nothing can be done, as the labour involved would be too much.

On Outdoor Plants.

Amongst the more important of outdoor flowering-plants, Hollyhocks are very subject to spider, and, unless means are taken to destroy it before it has got any considerable hold, the plants will be spoiled, as they will quickly become denuded of their under leaves, a state which, in addition to unsightliness, renders them too weak to flower satisfactorily. Regular use of the syringe or engine, with clean water, is the best means to keep the insects in check. As a preventive to the attacks of this pest, plants under glass, as well as wall fruits and other things grown out-of-doors, on which it is possible to cope with it, a sufficiency of water at the roots and overhead, in the shape of regular syringings, or the use of the garden engine, is indispensable and the only remedial measure possible. Any plant subject to the attacks of spider that is allowed to suffer at the root for want of water, is almost certain to become infested with it. Any check to vigorous growth appears to render the juices of plants more palatable to the spider, and better calculated to favour its

increase. Strong healthy growth, on the other hand, induces a crude condition of the sap, unsuited to the requirements of the insect. Plants in houses, that stand anywhere near forest trees that are subject to spider, such as Elms or Limes, are sure to suffer from it, as an infected leaf, blown in through an open light, is quite sufficient to introduce and establish a colony upon any plant on which it will live. T. BAINES.

Southgate.

THE BLACKBIRD.

MR. TILLERY, and some of your correspondents, seem so determined to destroy this glorious singer, the "Bad Shots" using traps, &c., to assist them in their work, that I send you a copy of a song on the subject by another well-known singer. If you reprint the song, it may, perhaps, soften the determination of some of your readers in their search after rat-traps and other engines for blackbird destruction.

R.

THE BLACKBIRD.

O BLACKBIRD! sing me something well:
While all the neighbours shoot thee round,
I keep smooth plats of fruitful ground,
Where thou may'st warble, eat and dwell.

The espaliers and the standards all
Are thine; the range of lawn and park:
The unnetted black-hearts ripen dark,
All thine, against the garden wall.

Yet, tho' I spared thee all the spring,
Thy sole delight is, sitting still,
With that gold dagger of thy bill
To fret the summer jenneting.

A golden bill! the silver tongue,
Cold February loved, is dry:
Plenty corrupts the melody
That made thee famous once, when young:

And in the sultry garden-squares,
Now thy flute-notes are changed to coarse,
I hear thee not at all, or hoarse
As when a hawker hawks his wares.

Take warning! he that will not sing
While yon sun prospers in the blue,
Shall sing for want, ere leaves are new,
Caught in the frozen palms of Spring.

—ALFRED TENNYSON.

NEWSPAPERS AS PLANT PROTECTORS.

MR. GUILFOYLE, of Merion, writes on this subject to the *Gardener's Record* as follows:—The weather is often so variable in winter and early spring, that, even under the most favourable circumstances, the gardener is frequently puzzled. Many a gardener in the country lives at a distance from his charge, as also do his assistants; expecting frost, fires are lighted before leaving off work; perhaps the men are scarcely at home when the scene changes, the sky is overcast, making fires a good deal worse than useless, because positively injurious to many things, with a waste of fuel besides. Slaking down of fires then becomes necessary, which would not be of much consequence if the men were resident in the garden; but when it comes to a mile or so across country it is no joke. And just as the gardener is indulging in the comfortable anticipation of a night's rest, the stars begin to peep out one by one till the whole firmament is studded over with them; frost again commences; he gets nervous about his plants, and he starts his fires again, sometimes not without a good deal of labour. Even if he does get to bed, he is up looking at the sky and the thermometer outside his window. Newspapers will relieve him of much of his care. He may spread them over his plants at nightfall in uncertain weather; the labour is slight; and, being so light, they will not injure the most delicate growths; and I know, from experience, that they will exclude a considerable amount of frost. They are also most useful in hard frosts as aids to the fires and inside frames, with or without mats. To gardeners growing specimen Pelargoniums, and other plants that do not like any excitement during winter, they are invaluable. They do away with the necessity of having strong fires. They ought to be thoroughly dried by being thrown across the pipes or flues, or by other means, before being put on at night. It does not take many minutes to cover a house of plants with them, and the security and peace of mind they give the gardener who is anxious about his charge is not to be undervalued.

[We consider the foregoing a valuable suggestion, and any of our readers can very easily give it a trial.]

THE KITCHEN GARDEN.

THE NEW AMERICAN POTATOES.

IN spite of what has been said in favour of Compton's Surprise, it will, I fear, not meet with any great encouragement from Potato growers in this country. It is noteworthy that it has not done well at Chiswick, and that it has also been much affected with disease. As has been stated in reports of Potato trials in America, this variety has a tall strong-growing haulm, and coarse haulm is generally allied to coarse ungainly tubers, which are rarely of good quality, and when disease prevails late in the season such Potatoes are the most certain of all to succumb to its ravages. The tubers of Compton's Surprise closely resemble those of the old Jersey Blue, or Paterson's Blue, being large and very deep-eyed. The flesh is white, but, in that respect, not superior to our purple kinds; whilst, as a table Potato, or for exhibition, it is not equal to Scotch Blue or Summer-hill Seedling, two of the handsomest and most acceptable purple-skinned Potatoes in cultivation. Who that has any taste for a good Potato cares about one that produces tubers from 1 lb. to 2 lb. in weight? Such kinds are only fit for cattle feeding, or if cooked for table they have to be cut into several pieces before they can be cooked, and Potatoes served up so are unacceptable. Nice medium-sized tubers, that will all cook alike, and which, when dished up, look like balls of flour, are the sort of Potatoes which are liked in this country. The extra early Vermont is, on the other hand, a Potato worth looking after, and enough of it has already been sold in this country to make it pretty abundant next summer. That it will supersede the Early Rose there can be little doubt, as it is earlier, more prolific, and has a dwarfer top—all points in its favour. Its quality is also good, as it received a first-class certificate at Chiswick after it had been cooked. It has, however, the fault common to nearly all American Potatoes—that is, it has a large number of eyes. Where it is desirable to increase the stock of any kind, that is an advantage; but, when the stock becomes abundant enough to store for table use, then a superabundance of eyes is undoubtedly a fault. In the case of this variety, a tuber 1 pound in weight has upwards of twenty eyes, all of which, instead of being deep, are rather prominent, and this characteristic will enable people in this country to comprehend the possibility of one pound of Potatoes being made to yield so many. Now, the evil of a superabundance of eyes is evident when tubers are stored. As such kinds soon spurt into growth, not one or two, but twelve or twenty shoots at once, the exhaustion of the tuber is most rapid. It is like having a full tub with twenty leaks in it instead of one or two; and, in consequence, it is sooner emptied. The Early Vermont is found to be quite flabby before Christmas—much more so, indeed, than even the Ash-leaved Kidney; and this is owing entirely to the excessive number of sap-exhausters which it has in the shape of eyes. Now, a really good keeper, because a much later ripener, is Brownell's Vermont Beauty, a remarkably fine and handsome Red-skinned Potato, and one as notable for the specific gravity of its tubers as it is for its even cropping qualities. It has the drawback of an abundance of eyes, but that is not so detrimental as in the case of the Extra Early Vermont, as it is much later in starting into growth. The shape of the tuber is that of an elongated flat-round, and it is remarkable that it never produces any small ones. The flesh is rather yellow, and boils soft and good. This variety has also an exceedingly short haulm, and was greatly admired at Chiswick. The Extra-Early Vermont has, I believe, escaped disease because it ripens so early, but Brownell's Vermont Beauty has not been so fortunate, and therefore must not be considered disease-proof. After all, there are few better American Potatoes than the late or pale American Rose. It is, however, not paler in colour than any other of the Rose family, and the skin is slightly netted. The medium-sized tubers of this variety are really handsome, and very telling in any collection. It is about a fortnight later than the Early Rose, which, in the haulm, it closely resembles. It is not probable that we shall ever beat the Americans in the matter of raising crops. Our tubers won't be so large, although we may get as many to a root. This will be no evil, but rather a gain, as we shall get better quality. A. D.

CULTURE OF PARSLEY.

PARSLEY must be produced in quantities at all seasons, for the kitchen, to be used in frying, boiling, stuffing, and flavouring many things, and, also, for garnishing purposes. Good curled leaved Parsley is everywhere now obtainable, and is no more expensive or troublesome to cultivate than the old plain-leaved sort was formerly. To grow it to perfection it requires good rich soil, and will pay for a good preparation as well as any known vegetable. It may either be sown in single rows as a boundary edging to cultivated quarters, in borders, or in beds, on quarters, in rows 12 to 18 inches apart. Make the first sowing in February and the last in July. Thin the sowings early, and keep them thoroughly clean by constant surface-stirring. Sow or transplant some in large pots or boxes, to be placed indoors, or otherwise sheltered in winter, so that a supply for the whole year may be secured. Respecting surface-dressings, there is no kind of manure, that I could ever discover, that produced such luxuriance and colour in Parsley, and kept it so free from canker, as light dredgings of fresh chimney soot. It is also a good plan, where there is no convenience of sheltering Parsley, or housing in pots in mid-winter, to select in summer some of the best bits, and carefully and methodically dry it, and, when done, to rub it up, and bottle it; I have found the best method for drying it is to place the leaves between paper, and never expose them to the full rays of the sun, thus it will dry a beautiful natural green colour without having its virtues dried or roasted out of it. Beds and borders of Parsley may always be sheltered partially when severe winter weather sets in, by placing round them a double row of short stakes, temporarily, and filling in between them with straw, Fern, Haulm, evergreen boughs, Heath, Furze, or roughly made bands twisted up out of any rubbishy material.

JAMES BARNES.

DEEP CULTIVATION.

DEEP culture has been recommended, and more or less practised for ages, and there cannot, I think, be a doubt that deeply-worked land renders us in a great measure independent of the seasons; or, rather, what I wish to convey is, extremes of dry or wet weather do not disastrously affect land that has been deeply-stirred for a series of years. In a wet season, the excessive rainfall easily percolates through the deeply-worked land without doing any injury, whilst in a season of drought the roots meet with no impediment in their descent to the cool deep stratum, in search of the necessary moisture to carry on growth. Deeply-stirred land, too, is warmer, and, consequently, earlier, than that which is only subjected to a mere surface digging or scratching. And it is less urgent to follow out to the letter any particular system of rotation of cropping. Even this is a great gain; for in a garden that is closely and continuously cropped, any particular system of rotation cannot always be strictly adhered to. And, in addition to all this (taking a series of years), its general adoption will pay by increased crops, and, by reducing the necessity for watering so much in dry weather, for the extra labour incurred in moving the earth deeper. I think, however, there is a right and a wrong season for performing even trenching, and which depends principally upon the character of the soil and sub-soil of each particular locality. For instance, the sub-soil of a large portion of this county is composed of what geologists call "the Oxford oölitic clay," and is of considerable depth or thickness. As a general rule, all trenching should be performed upon soils of this character in the autumn or early winter months, for the coarseness of the granules or fragments of soil, if deeply trenched in spring or summer, may become so excessive as to render it unfit for cropping within any reasonable time. I have known this to occur even where there was no particular difficulty in working up a fine tilth on the surface. The land, in fact, lacked the necessary firmness or consolidation, and was, for the time being, almost barren from this cause alone. Judging from my own experience upon different soils, it is always best to proceed cautiously in introducing any new system, unless we are thoroughly acquainted with the chemical composition of the soil we are working upon; as I believe it takes several years' experience in the management of some soils before the best mode of treatment can be discovered and practised with certainty as to results. I should say, however, this has reference more especially to heavy cold clay lands, as the various kinds of sandy loams may be trenched at any time when opportunity serves. One good rain is generally sufficient to consolidate it for the reception of almost any crop except Onions, Broccoli, Cabbage, or Strawberries, which always do best in land that has been deeply-stirred and afterwards settled. E. HOBDAY.

NOTES OF THE WEEK.

— THE work of laying out Leicester Square is rapidly progressing. We strongly recommend a broad sweep of fresh green turf in the centre in place of the contemplated gravel walks and central fountain.

— WE understand that a consignment of hardy North American plants is to be sold at Stevens', on Thursday next. Among these are the beautiful *Cypripedium spectabile*, *Sarracenia purpurea*, *Trilliums*, and other plants of that description.

— THE Botanic Garden at Adelaide, South Australia, has been enlarged by the addition of eighty-three acres, for the laying out and planting of which a sum of £6,000 has been granted by the Government.

— THE transformation of the old State kitchen-garden at Versailles into a national school of horticulture has already commenced. M. Hardy, for many years chief gardener at Versailles, has been appointed director of the new institution, and is about to visit Holland and Belgium, in order to become acquainted with the arrangements of similar institutions in those countries.

— THE rare *Aloe abyssinica* has just flowered in Mr. Peacock's collection at Sudbury House, Hammersmith. This species is a robust grower, bearing great smooth glaucous leaves, dentate along their margins, and it differs from most of its congeners in the colour of its flowers, which are a clear yellow throughout, and borne on spikes with 8 or 10 branches, while nearly all the other species in cultivation bear orange or orange-scarlet flowers on spikes with fewer divisions.

— NO DOUBT many think that those beautiful Tulips now to be seen in Covent Garden Market are grown in the pots in which they are sold, but they are not. Market gardeners insert their Tulip bulbs very thickly in boxes or pots, and therein grow them until they are nicely bloomed, when they turn them out of the pots or boxes, and pot them afresh, placing from four to five bulbs in each pot. The Tulips being thus transferred with as good roots as possible, and otherwise treated kindly, soon make abundance of fresh roots, and do not suffer in the least from the shift.

— IN the last number of the *Gartenflora*, Dr. Regel figures and describes, under the name of "*Geranium Backhousianum*," a very handsome species which he received some time since from Messrs. Backhouse, of York, under the name of *G. Lambertianum*. He states that, although nearly allied, the two species present very marked points of difference, *G. Lambertianum* being distinguished by its geniculate branching stem, which, as well as the branches and leaf-stalks, is covered with thinly-set hairs; by its leaves being bluntly-toothed, and less deeply lobed; and by the lilac colour of its flowers; it is figured and described in Sweet's "*Geraniaceæ*," vol. iv., tab. 338.

— ACCORDING to a Blue-book return, just published, the extent of land used for fruit-trees of any kind in Great Britain in 1873 was 148,221 acres. This is a smaller acreage than was returned in 1872; but the decrease has chiefly occurred in consequence of incorrect returns under this head in previous years, in those parts of England where fruit-trees are not extensively planted, and in Wales. The extent of market-gardens in Great Britain in 1873 was 37,884 acres. Of this number 34,743 acres were in England—the counties of Middlesex, Essex, Kent, and Surrey containing 15,542 acres, or 44·7 per cent. of the market-garden land in England.

— Two very interesting lectures on the history, government, and products of Japan were delivered during the last week in January to the *employés* of Messrs. Veitch & Son, in the institute provided for the comfort and convenience of the young gardeners employed in the Royal Exotic Nursery at Chelsea. The lectures abounded in anecdote and useful instruction, and were illustrated by numerous specimens of Japanese books, china, toys, drawings, and other articles collected by the late Mr. John Gould Veitch. The attempts made by Messrs. Veitch & Son to improve the social status of their numerous *employés* ought to bear good fruit, and we hope that other firms will follow their excellent example.

— THE present winter being not only unusually mild, but also in the district of Wigtonshire unusually dry, it may be interesting to record some of the results of such weather. There are in bloom in the gardens at Airlour, Port William, the following plants, viz., *Aubrietia deltoidea* and *grandiflora*, *Anemone coronaria* and *Hepatica*, *Myosotis dissitiflora* and *sylvatica*, *Omphalodes verna*, *Scilla sibirica* (not quite expanded), *Erica carnea*, Snowdrops, *Cyclamen Coum*, *Crocus* (yellow and purple), *Primula denticulata*, double and single Primroses of all colours except white, *Auricula*, *Soldanella alpina*, *Saxifraga Cymbalaria*, *Linaria Cymbalaria*, *Schizostylis coccinea*, *Nemophila insignis*, *Eranthis hyemalis*, *Arabis albida*, *Pulmonaria mollis*, *Helleborus niger* and *abchasicus*, *Tritoma Uvaria*, intermediate Stocks, Wall-flowers (single and double), *Vinca major* and *minor*, *Laurustinus*, *Jasminum nudiflorum*, China Roses, Daisies in variety, Violets, Pansies, *Polygala Chamæbuxus*, *Lithospermum prostratum*, *Garrya*

elliptica, *Cydonia japonica*, Spurge Laurel, *Arbutus*, *Berberis Aquifolium* and *nepalensis*, *Phlox frondosa*, *Symphytum caucasicum*, and *Dondia Epipactis*.

— LIVERPOOL is to have an aquarium and winter-garden. An excellent site, near the Philharmonic Hall, has been secured, and the greater part of the capital has, it is said, been subscribed without any public appeal. It is in contemplation to build an aquarium, conservatory, and other buildings, at an estimated outlay of £45,000.

— *CAREX BACCANS* is now fruiting in the Palm-house at Kew. It has bright green grass-like leaves, and bears nodding branched spikes of crimson berry-like fruits of quite an ornamental character, on stems about 2 feet in height. It comes from the Himalayas, and if well grown, would make a desirable plant for conservatory decoration, while its graceful spikes would be useful for cutting.

— THE article on red spider, which forms our leader this week, is one of a series, by Mr. Thomas Baines, the well-known plant-grower. It is rarely we find the highest cultural skill accompanied with the power of fully expressing, in writing, the knowledge on which that skill is based, but that these qualities are combined in Mr. Baines is well shown by his writings. We commend these articles to our readers, as the best ever written on the pests of our gardens.

— A COLOURED illustration of Bradley's new Strawberry, named *Amateur*, is given in the *Florist and Pomologist* for this month. It is said to be a great bearer and a free grower. Its fruit, which keeps well, is large, obovate, cockscombed, and of a deep red colour, both outside and inside. It has been awarded a first-class certificate by the Royal Horticultural Society, and is a valuable late Strawberry, which comes into use just before the Frogmore Late Pine.

— THE exhibition of appliances for the economic consumption of coal, which has been formed in the Peel Park, Salford, by the Society for Promoting Scientific Industry, was formally opened on Friday. Mr. J. Lowthian Bell, who had been announced to open the exhibition, was prevented from being present, but forwarded the copy of an address which he had intended to deliver. This was read by the secretary, Mr. Larkins. The exhibition will remain open some weeks, and will, doubtless, receive its share of public notice when the elections are occupying less attention than they are at present.

— *DRABA BRUNIIFOLIA*, a very diminutive yellow-flowered species from the eastern Caucasus, is figured and described by Dr. Regel in the last number of the *Gartenflora*. It forms dense tufts of leaves, arranged in rosettes, which are each about $\frac{1}{2}$ inch in diameter, and in June and July are surmounted by an abundance of golden flowers on stems about 2 inches high. The plant is nearly allied to *D. aizoides* and *D. cuspidata*, but, according to Dr. Regel's experience, is much hardier than either. The plants of *D. bruniifolia*, which flowered last year in the Botanic Gardens, St. Petersburg, were raised from seed gathered at an elevation of 8,000 feet.

— AMONG plants figured in the *Botanical Magazine* this month are *Stapelia Corderoyi*, a dwarf singular-looking kind from southern Africa; *Iris Douglasiana*, a showy Californian species, with flowers varying from white to lilac-purple; and *Odontoglossum roseum*, an old acquaintance recently imported by Messrs. Backhouse, of York. It is a variable plant, the best and larger forms of which remind one of the new *Mesospinidium volcanicum*, both in habit and flower, and, like that species, it has one leaf on its two-leaved bulbs smaller than the other. Its flowers are of a rosy colour, varying to reddish-crimson, the column and base of the lip being creamy-white. The lip is slightly adpressed to the column, as in *Mesospinidium volcanicum* and this gives the flowers an Epidendroid appearance. It is a free bloomer, and, when well grown, very showy. In the figure in question the bulbs are much too highly coloured. Of *Gaillardia amblyodon* and *Solandra oppositifolia*, both figured in this number, notices will be found in other columns.

— MR. ELLACOMBE writes to us from Bitton Vicarage, and sends the following list of plants in flower in his garden there, Feb. 2:—*Galanthus nivalis*, *G. n. pleno*, *G. plicatus*, *Crocus moesiacus*, *C. susianus*, *C. biflorus*, *C. b. Parkinsoni*, *C. lagenæflorus*, *C. Aucheri*, *C. luteus striatus*, *Primulas* (single and double), *Rhododendron atrovirens*, *Kerria japonica*, *Hepatica alba*, *H. a. stam. rubris*, *H. rubra*, *H. r. pleno*, *Leucojum vernum*, *Daphne Froniana*, *D. indica rubra*, *D. Mezereum*, *D. pontica*, *Eranthis hyemalis*, *Vinca major*, *V. minor*, *Garrya elliptica*, *Gorse*, *Petasites alba*, *Anemone hortensis*, *Lonicera fragrantissima*, *Tussilago fragrans*, *Cydonia japonica*, *Viburnum Tinus*, *Erica herbacea*, *E. codonodes*, *E. mediterranea*, *Helleborus niger*, *H. n. major*, *H. cupreus*, *H. orientalis*, *H. antiquorum*, *H. abchasicus*, *H. lucidus*, *H. dumetorum*, *H. odoratus*, *H. atrorubens*, *H. olympicus*, *H. purpurascens*, *Arabis albida*, *A. rosea*, Pansies, Daisies (single and double), *Cyclamen Coum*, *C. vernum*, *C. Ibericum*, *C. I. album*, *Mahonia japonica*, *M. Aquifolium*, *Sisyrinchium grandiflorum*, Violet Czar, *Chimonanthus fragrans*, *Iris stylosa*, *Iberis semperflorens*, *Clematis cirrhosa*, *Scilla sibirica*, *Hyacinth* (small white), *Omphalodes verna*, *Jasminum nudiflorum*.

THE FLOWER GARDEN.

FLOWER GARDEN DATURAS.

By W. THOMPSON, Ipswich.

AMONG the numerous plants available for garden decoration, but which are mostly conspicuous by their absence, several species of annual *Daturas* occupy a prominent place. Whether the fact be due to the abundance of the material offered nowadays to the gardener's hand, to the fastidiousness of modern horticultural tastes—which thrust aside all plants unfit for exhibition purposes, for the button-hole, or for the decoration of the dinner-table—or whether it arises from the somewhat weedy character of their foliage, it is none the less certain that the best of them are far more rarely grown than they deserve to be, in spite of the defect alluded to, and which they share with so many other members of the same family. The genus includes five or six species, possessing some claim to notice, but those which more especially merit the attention of the amateur are the *D. ceratocaula*, the *D. meteloides*, and the *D. fastuosa*, with its double varieties. The first-named, *D. ceratocaula*, is probably one of the best known. It grows from 2 to 3 feet high, branching dichotomously; the foliage, which is less obtrusive than in most of the species, being lanceolate, with sinuated margins, and hoary beneath. Its somewhat defective habit is amply redeemed by the noble, sweet-scented, trumpet-like flowers, produced from the axils, the corolla being often 6 inches in length, and 4 or 5 across the limb, which is white, tinged with violet-purple externally and at the angles. The calyx in this species is cleft on one side, and the pendulous seed-vessel quite smooth. The flowers, both of this and the following species, expand towards the close of the afternoon and close the following morning. The *D. meteloides*, a native of Texas, of which a figure is here given, differs from the preceding in its broader foliage, which varies from ovate to cordate-ovate, as well as in its somewhat large flowers, in its calyx-tube not being split on one side, and in the capsule being spiny; the limb of the corolla is usually more completely suffused with pale violet, and, like the *D. ceratocaula*, it is fragrant. The *D. fastuosa*, if less remarkable for the size of its flowers than the species already referred to, has, nevertheless, merits peculiar to itself. Even the single form of this plant, which in the type is creamy-white on both surfaces, yields a very effective variety with the corolla of a deep violet externally, the interior being white, as in the type; but the most striking forms of this species are those bearing double flowers, the primary corolla having a second, and, sometimes, a third arising from its tube, all perfectly regular in form, and often parti-coloured, as in the single variety with violet flowers. The *D. fastuosa* Huberiana, of the seed catalogues, and several varieties of it which are offered, are reputed to be hybrids of this species with the dwarf *D. chlorantha* fl. pleno or *D. humilis* flava of the gardens; but, although they offer a greater variety of colour, they are less hardy than the older forms just described, and appear to require a warmer climate for their complete development. The culture of these *Daturas* offers no especial difficulty. Fresh seeds are readily raised in an ordinary hot-bed, and the young

plants should be pricked out singly in pots while small, and finally planted out where they are to stand. They need ample space for their full development, and should be grown in light sandy soils in preference to such as are of a heavier nature. But few gardens exist where appropriate situations for one or more of the species may not be found, and in most there is abundance of room for all those here named. It may prove an additional recommendation to some amateurs that most of the *Daturas* thrive well in the neighbourhood of the sea.

HARDY LADY'S-SLIPPERS.

(*CYPRIPEDIUM SPECTABILE*.)

As I feel sure that this extremely handsome hardy Orchid is not nearly so well known as it ought to be, I am induced to say a few words respecting it. It certainly is one of the finest, if not the very finest, hardy Lady's-Slipper that has, as yet, been introduced, and it is by far the easiest to cultivate; when strong, it attains a height of from $1\frac{1}{2}$ to $2\frac{1}{2}$ feet; each stem bearing at its summit from one to three large handsome white flowers, with a deep rose, much-inflated lip, though in some varieties the lip is so delicately tinged that the flower is nearly all white. It is a fine sight to see a strong tuft of this noble plant, with from twelve to twenty stems rising from one root, bearing from thirty to forty flowers. This could have been seen last year at the York Nurseries; in fact, the plant was flowering there so freely that it would have been an easy matter to have cut a hundred blooms at one time. In gardens where there is a natural bog, or a wet place, by turning in a few barrow-loads of peat-bog, leaf-mould, and sand, this plant might be grown to perfection. It also thrives well planted in a shady part of a *Rhododendron* bed. I have adopted the following plan of growing it, for these last six years, and have found it to answer well, as the plants both grow and increase in number: I select a bed $3\frac{1}{2}$ feet wide, and long enough to accommodate the quantity of roots which I have to plant, in such a situation as to be screened from the mid-day and afternoon sun; I then

Datura meteloides.

dig out the ordinary earth 18 inches deep, enclosing the bed by common building bricks placed on end; I then make it up to about 14 inches, that is, to within 4 inches of the surface, with a compost consisting of three-parts peat-bog, one-part leaf-mould and river sand; I now set the plants in their proper positions, taking care to carefully spread out their roots horizontally, as this Lady's-Slipper always roots in that way when there is sufficient room for it to do so. I then cover them with about 3 inches of the compost just named, leaving the bed in a light state, as the rains and watering are quite sufficient to consolidate it. During their growing season the plants are copiously supplied with water, and they receive no protection at any period of the year. When they have had a season's growth, the bed will have sunk about 3 inches lower than when it was first made, and, by laying on it 3 inches of the compost mentioned above, the plants, when they commence to grow, will make an effort to rise to the surface by lengthening their rhizomes and freely emitting new roots into the fresh covering. The following winter I take them up carefully with

a fork and cut away the upper part of the rhizome, with its new roots, from that which is below, and, if the plants have been well supplied with water during their growing season, the old roots will divide into two or three, and thus furnish new plants. I have tried to raise this Lady's-Slipper from seed, but without success.

R. P.

York.

THE TREE-HEATH.

(ERICA ARBOREA.)

YOUR correspondent, "Enquirer," wishes for some further information respecting this Heath, to which a brief allusion was made at page 12 as being then in full bloom in Messrs Lee's Nursery at Feltham. This species of Heath, for such it really is, as its name indicates, possesses a true arborescent character, in proof of which I may adduce the fact that in my juvenile days I well remember climbing into a bush of it nearly 10 feet high to inspect a robin's nest. It is, however, many years since I have seen a specimen of anything like that size; still, no doubt, in the south-west of England, and in Ireland also, some true representatives of the typical character of this old plant are yet to be met with. The great drawback to its full development arises from the serious effects of heavy snow storms. The myriads of tiny leaves arrest every flake that falls upon them, and the brittleness of the wood, especially marked under the influence of a severe frost, which causes it to split in all directions with the weight of superimposed snow, snaps off even strong-looking vigorous stems, or bends the tops level with the ground, while at the bend itself an entire disruption of the tissues in a longitudinal direction takes place, the result being that the plant has to make a fresh start in life from the old stump. This ordeal occurring every few years, renders its true arborescent occurrence of an exceptional character. Perhaps this is as well, as in such old plants the blooms are few and scattered, and certainly would not justify the remarks made on the appearance of the plants at Feltham Nursery. There, unquestionably, the vigour of youth, would be well exemplified, both in the denser character of the foliage, and in the larger, as well as more bountiful, production of blossoms. Seeing that our friend the Tree-Heath, though it has been a denizen of our gardens for a couple of centuries at least, is rarely met with, I will endeavour to give a brief description of its appearance. Like many of its congeners, its leaves are exceedingly narrow, arranged in whorls of threes round the stem, which, being of a slightly grey colour, gives a nice contrast to the foliage, varying from light to dark green, according to the vigour of the growth. In habit, the branches rise somewhat erect, but in old plants they acquire a more spreading character. The flowers are small, slightly campanulate, usually called white, but more correctly characterised as white suffused with a delicate lilac. They are not, as in many other Heaths, grouped into dense heads, but are scattered along the previous year's growth, charmingly intermingled with the slender foliage, which makes them so appropriate, as giving a spray-like elegance to any grouping of cut flowers. From this brief description, it will be at once seen that it possesses no ordinary value as a decorative plant; but I must caution my readers that it is the most tender of our hardy Heaths. Such a winter as 1859-60 cut it off root and stump in many localities, and to this fact is its rarity to be attributed. Nor will this be at all surprising when I say that its home is in Greece and in those happy climes bordering on the Adriatic; and in Sicily it is associated frequently with the Date Palm. The greater wonder, to my mind, is that it stands our climate at all, rather than that it should suffer from these ever-recurring seasons of Arctic winter to which we are subject.

As regards soil and cultivation, it will grow freely wherever Rhododendrons thrive. Like all the representatives of the natural order to which it belongs, it abominates lime and chalk, and all soils containing such ingredients. Its propagation is readily affected by the process of layering; not, be it noted, in the Picotee and Carnation sense of the word, but merely by placing round the neck of the plant a little bank of nice sandy peat, gently pressing the stems outward, so that the two-year-old wood becomes bedded on this cushion, placing as much of the same material above the branch as

will hold it down, and finishing off with a stone—a flat circular paving-stone answers admirably; it keeps the soil cool and moist, and, moreover, prevents the birds from scratching it away, which, without some protection of that kind, they are sure to do. Should the plant on which you propose to operate be old, and the branches proceed from the stem some little distance above the ground, do not attempt to bend them down, as they are sure to break; but, lifting the root, lay the whole plant down on its side, and then proceed as before described. To this exceedingly mild winter it must be attributed that the plant mentioned in your columns has blossomed at such an early period—April and May being its general time. A close ally to the subject of our notice is *Erica mediterranea*, hardier in constitution, almost as vigorous in habit, but, owing to its more upright growth, even more liable to damage from snow-storms; and, though not blooming so profusely, well worthy of cultivation. Of this we have many dwarf varieties, most of which are free spring-bloomers; but I have sundry doubts as to whether they are correctly referred to the old Mediterranean Heath at all. But there is one species I must not omit, namely, *Erica australis*. It is a most abundant bloomer, and would rival many of our greenhouse Heaths. Its flowers are a deep lilac, produced in such masses as almost to hide its deep green foliage. It grows freely, is hardier, somewhat dwarfer than the Tree-Heath, and has no equal amongst our taller-growing hardy Heaths.

Botanic Gardens, Hull.

J. C. NIVEN.

EFFECTIVE FLOWER BEDS.

A LOVE of plants is a very different thing from a mere love of flowers. Now that the extreme rage for bedding plants is on the wane, there is some chance of a wider range of plants becoming known to, and cultivated by, amateurs, and a deeper knowledge of gardening and plants induced, not merely a surface knowledge, such as is required for the ordinary style of bedding-out florists' flowers. It is, perhaps, hardly fair to disparage a system that has satisfied so many, for so long, without, at the same time, proposing a substitute, and to those who are, as yet, mere lovers of show flowers the following combinations for beds of hardy and annual plants, may not be useless. The climate of Scotland is generally considered suitable for these last, but Edinburgh, where the situation is exposed, and the soil light and warm, is not, naturally, the best locality for delicate fragile seedlings, and, therefore, it is right to explain that annuals, grown under such circumstances, require more trouble and preparation of the soil, than are needed for variegated Geraniums, for instance. One seldom sees now the finely raked border, and a neat row of rings, with a stick in the centre, and the name of the annual stuck through the split stick; often was the name the only thing seen of the seed. Deep hoeing did not answer for fine raking, so the soil was a solid cake below the dressed surface; now, annuals must have cool and well-worked deep soil to do them justice, or rather to enable them to grow at all and flower for any length of time. The beds of hardy and annual plants, which I shall now enumerate, possess an amount of show and colour sufficient to make them attractive, and they remain long enough in flower to satisfy any reasonable lover of a garden. I may observe, too, that, with the exception of No. 7, which was seen in perfection at Messrs. Jackmans', at Woking, and No. 19, I have not happened to meet with any of these beds which we have tried ourselves, and found to suit our garden.

1. I begin with the latest-flowering bed which I have, and which is now (January 20) covered with little white stars, viz., *Aster ericoides*, the first flowers of which expanded in October. This is a remarkably neat-growing plant, and its Heath-like appearance is attractive, even when not in flower. The pair of small beds which I have of it consist of a centre plant of Golden Queen Holly, the outside edging *Euonymus radicans* variegata, the rest being filled with alternate plants of the little Aster and dwarf double-red Sweet William. Even when done flowering this *Dianthus*, owing to its dark reddish foliage, contrasts well with the variegated evergreens and light growing Aster.

2. *Campanula carpatica* (blue), with a broad edging of the yellow *Oenothera missouriensis*. By preventing the *Campanula*

from seeding, this bed will last a mass of flowers nearly four months, beginning with June and July.

3. *Ononis rotundifolia* (Rest Harrow), a bright pink Pea-flowered plant, mixed through with *Dactylis glomerata variegata*. This makes a lovely summer bed.

4. Common double white Pink, edged with *Heuchera lucida*. Among the Pinks are small single red Tulips, which come up and flower year after year, and which well contrast with the grey foliage of the *Dianthus* and blue *Scilla bifolia*, through and outside the brown-leaved *Heuchera* edging. This bed in summer is a mass of white, and, by dotting in a few plants of crimson Mule Pinks, there are some flowers in autumn. No. 4 is a good winter and spring bed, and a most fragrant one in summer.

5. Alternate plants of *Erica carnea præcox* and *Heuchera*, with room between each of these permanent plants for a tuft of *Campanula carpatica*, or *C. turbinata*; or, if an annual is preferred, dwarf China Asters, purple, pink, and white; or *Tagetes signata pumila*, the lively green foliage of which is pleasing even before the plant comes into flower.

6. (Large bed), centre plant, Golden Yew, the rest of the bed being filled with three shades of red, consisting of the *Phlox Drummondii* pegged down twice, either mixed, or shaded, from light to dark, or *vice versa*, according to taste. The mass of *Phlox* is surrounded with a belt of the pure white *Oenothera marginata*, and an outside edging of *Heuchera*. *Dianthus Heddwigi* would do equally well with the permanent plants, if a change is wished from the *Phlox*; both come into flower early in July, and are superior to *Verbenas*, and last until November, when the winter beds require to be planted.

7. *Clematis Jackmanii*, and its varieties, edged with *Vinca major elegantissima*, minor *aurea* or *argentea*, or *Euonymus radicans variegata*, or *Lonicera reticulata*, but, although hardy, this last loses most of its leaves in winter, and *V. elegantissima* is spoilt by severe frosts; the small *Periwinkles* and *Enonymus* are surest. I was surprised to find, on cutting over the *Clematis* this winter, fine roots where it had been pegged down, as I had always thought it must be increased by grafting. If a high bed is wished for, some suitable branches for the *Clematis* to crawl over, quickly make the bed any height desired. I have seen *Tropæolum speciosum* grown in this way in Perth and Aberdeenshire with most brilliant and beautiful effect, but it does not succeed about Edinburgh. The *Clematis*'s first flower opened in July, and the last in November.

8. *Erica carnea* or *præcox*, *Violas*, and *Pansies*, in alternate lines or rings, and in colours according to taste. It is hardly possible to go wrong with this bed. When the *Heaths* are too much grown to admit of *Violas* between them, and you are not inclined to part them, *Phlox Drummondii* (mixed) will give bright eyes of colour all summer and autumn, and, if thinly planted, will do not the least harm to the *Heaths*, which, of course, must never be overgrown by other plants, but, by clipping over the dead flowers, and trimming in sprawling pieces, they will last for years undivided, if so wished.

9. *Dactylis variegata* and *Phlox Drummondii* intermixed make a light mixed bed.

10. *Anemone Honorine Jobert* (white) alternated with *Chrysanthemum Bob* (dark red), the edging being *Heuchera*, makes a pretty bed.

11. The small *Fuchsia pumila*, with white *Vittadenia trilobata*, makes a very neat and lasting bed. Some think the *Vittadenia* too like a Daisy, but I am fond of all rayed flowers, and prize any plant that lasts six months in flower; it sows itself (if one chooses to let it), stands the early frosts, fades into pinkish-lilac, so as to produce various shades of colour at the same time on the plants, and requires no pegging or cutting off of dead flowers. As it is not a Daisy, it does not shut up in sunless weather, or in the afternoon. It also makes a good hardy greenhouse basket plant.

12. Groundwork, the little yellow *Oenothera prostrata*, thinly dotted with *Viola Perfection*, or any other purple, lilac, or blue *Viola* or *Pansy* of compact habit.

13. Centre plant *Yucca gloriosa*, set in a groundwork of dark blue *Ajuga purpurascens* (summer), dotted with *Sedum spectabile* (autumn), the last having fine large pink tassels of

bloom which stand the first frosts. This bed is edged with variegated Ivy.

14. Groundwork, the lovely *Mesembryanthemum tricolor*, dotted over with *Echeverias* of different sorts, and edged with *Antennaria tomentosa*. By the time the groundwork has ripened what seed is required, and the plants are removed (not that this is necessary in the case of this *Mesembryanthemum*, as it spreads out so regularly, and the flat red fleshy seed-vessels are peculiar-looking), the *Echeverias* are in bloom. I was surprised and delighted by the way in which the little *M. tricolor* flourished and opened freely in the wet summer of 1872, a circumstance I suppose to be attributed to our light soil, which would be the better for rain every second day; the only thing we have to guard against is, to see that the boxes of seedlings are thoroughly and gradually hardened off before planting out; when so prepared they can be turned out in the middle of the hottest day, require no watering, and do not give the least trouble, and we find that this little succulent is one of the quickest of annuals to flower. I fancy by having two sowings, and not saving seed, we could have this groundwork in perfection the whole season, except during the short interval between the second planting and flowering of the same. I mean to try it, for this bed was beautiful, and gave us no trouble.

15. Large or small beds of *Dianthus Heddwigi* are invaluable. This year, some beds were the admiration of every one, both nurserymen and amateurs. We never had such beautiful Chinese Pinks, of every shade of red, from delicate pink to dark blood red, lilac to purple, white, and all degrees of blotched, and streaked and spotted in every delicate shade, and decided markings.

There were twenty small divisions filled with these bedding *Dianthus*, and in each compartment there were different varieties. We regretted having to transplant them, still in flower in November, on account of some necessary alterations that had to be made in the beds. The *Dianthus* were edged with *Artemisia Stelleriana*. They last well in water, and bear close inspection.

16. Large bed (to look down upon); centre plant, a tuft of best Gardener's Garters (*Phalaris arundinacea elegantissima*), surrounded with *Aster bessarabicus* (best blue), then scarlet *Pelargoniums* (somewhat large plants), a band of *Helleborus niger major*, the edging being alternate plants of purple-leaved *Plantago rubescens*, and *Funkia japonica cordata*. As all our beds and borders are edged with hardy bulbs, No. 16 has flowers in winter (Christmas Roses), spring (Crocuses), summer (scarlet *Geraniums* and lilac *Funkia* bells), and autumn (Asters); and, owing to the variety of shape and colour of the foliage-plants, beauty is still maintained in the intervals between the times of flowering of the different plants. *H. niger major* should be grown for a foliage plant, even if it never flowered. In old gardens in the north I have, at a distance, mistaken clumps of this Christmas Rose for those of *Pæonies*.

17. Centre plants *Spiræa*, with one plant of *Tritoma grandis* on each side. These three plants were surrounded by *Delphinium formosum* (selected seedlings of good clear blue), the small double yellow Sunflower, then a ring of alternate plants of *Saxifraga cordata*, and the finest and earliest flowerer of the large-leaved *Saxifrages*; one we got unnamed from Mr. Niven, of Hull, belonging to the *Ciliata* type. This bed is edged with *Heuchera*, and between each *Saxifraga* are dwarf Lilies, *L. venustum* (red) or *L. superbum* (yellowish), alternated with the white trumpet *L. eximium* or *longiflorum*, and between every plant of *Delphinium* and Sunflower is *L. croceum* (orange). This bed has flowers in it in spring (dwarf *Narcissus*, for bulb edging, and *Saxifrages*), summer (*Spiræa*, Lilies, and *Delphinium*), and autumn (Sunflowers, Lilies, and *Tritomas*, which last continue to flower long after the Sunflowers).

18. Foliage-bed—Centre plant, Golden Yew, surrounded with *Cineraria acanthifolia* or *Centaurea ragusina*, the last of which stands most winters with us. The *Cineraria* is perfectly hardy; we did not have it, however, in 1860-61. Then a broad mass, pegged down, of Red Spinach (seed from Belvoir—very superior to what is usually bought as Red Orache, and does not acquire so much of the rusty colour when old. Next a ring of pegged *Artemisia annua*, the outside edging by the

Grass being *Stachys lanata*. This bed was so satisfactory, that we had it two or three years in succession, and the Spinach came up of itself more than we required, although the beds had been filled for winter, and thoroughly dug.

19. *Lobelia fulgens* intermixed with *Tussilago Farfara* variegata. This is a grand bed, and unlike every other; but I must admit that the *Lobelia* does not succeed with us as I have seen it in Dumfriesshire, where the climate is damp and the soil heavy—conditions which suit both plants. The dark red-pointed foliage of the *Lobelia* contrasts well with the round bold Coltsfoot, and it is a good bed before the intense scarlet flower-spikes come into bloom.

For a distant bed or row—to shut out kitchen-garden crops, for instance—alternate plants of *Symphytum officinale* fol. var. and *Dielytra spectabilis* make a beautiful combination, both of colour and form; and I was much struck by it when first I saw it in a friend's garden. By persistently pinching out the flower-buds of the Comfrey, the plants are kept bushy, and do not run up, as they naturally incline to do; and, by preventing its flowering, the fine creamy foliage is kept handsome much longer than it otherwise would be. Pinching out is a far better plan than cutting over the flower-stems, which we used to do, thus having fine variegated leaves close to the ground. By pinching, you have a big bush covered with fine leaves.

Vinca major elegantissima, grown as a pillar about 5 feet, for back rows of herbaceous border, looks uncommonly well; the effect is finer and the growth more graceful than either variegated Ivy or variegated Bramble, and it is not deciduous like *Acer Negundo*. When the large blue flowers are in bloom it must be beautiful; it has stood unhurt through the winter, from 1869 to 1874, and when I saw it at a distance I mistook it for *Cobæa scandens* variegata.

My list of our proved hardy beds is not exhausted, but the arrangements I have mentioned must suffice for the present; our beds are all on Grass, and, being circles and ovals, simple in shape, the Grass-cutter runs round them all without loss of time, and, in clipping the edges, the shears have not to be lifted and reversed.

One of the most immediate benefits gained by filling beds with the plants recommended in this paper, and one patent to all, even rigid bedders-out of exotics, is, that the extent of glass, always too limited and over-crowded, even in the largest places, at times, is set free for its legitimate occupants and the miserable crammings, and makeshifts for storing away the struck and lifted bedding stock, through the winter, and still more harrassing time of spring, are done away with. Not merely does the bedding system, carried to extremes, curtail the variety of plants in our flower-gardens, but the interesting and valuable contents of frames, greenhouses, and stoves, are all injured and limited on account of this one object; even Vineries and Peach-houses are not improved by the multifarious and multitudinous collections of bedding-plants that are thrust into them.

F. J. HOPE.

Wardie Lodge, Edinburgh.

A HINT FROM NATURE ON PLANTING CYCLAMENS.

WHILST walking round my garden the other morning, admiring the beauty of *Crocus Imperati* and its various relatives of the early-flowering group, with fifty other gay and beautiful flowers basking in the sun, I came to a fine tuft of *Cyclamen hederæfolium* some 18 inches in diameter, with splendidly marked foliage of dark and light green, shining like wax, and lighted up with the bright red flowers of *Cyclamen Ibericum*, the root of which had strayed or come from a chance seedling in the midst of the ample foliage of the more robust *hederæfolium*, forming an exquisite group. This hint afforded by nature was not to be disregarded, therefore I at once set to work to group some others of the spring-blooming section in like manner. *C. hederæfolium* and its more finely marked var. *græcum*, are splendid plants for the border or for rock-work, when well grown with some 100 to 200 flowers springing from a single root, succeeded by its beautifully marked foliage, lasting the dreary winter months through, but the absence of well expanded leaves whilst blooming in some measure detracts from its merits in the opinion of some, yet, when its ample and exquisitely marked foliage is fully developed and

mixed with the flowers of the spring-blooming section, the bright red of *Coum*, *Ibericum*, &c., and the pure white of *Atkinsii*, the combination so formed is not to be surpassed, more especially at this dull season of the year. The foliage of the spring-blooming section being rather scant in proportion to the abundance of their flowers, the charms of both are much increased by the combination.

J. ATKINS.

Painswick.

Rare Species of Tulips.—I have read with intense interest Dr. Regel's article on the various species of Tulip, and I sincerely hope and trust it will stir up all those who have the means and the opportunity to procure and grow all the known species of this beautiful family. I have lately been endeavouring myself to procure living bulbs of all the species I could get hold of, and have now the following:—*T. sylvestris*, *T. pulchella*, *T. Biebersteiniana tricolor*, *T. biflora*, *T. fragrans*, *T. bæotica*, *T. Oculus-solis*; *T. Persica*, *T. Gesneriana maculata*, *T. viridiflora*, *T. carinata-rubra*, *T. retroflexa*, and *T. elegans*. I shall be glad to know to what species the four last-named really belong. I have had, but lost, *T. Orphanidea* and *Celsiana*. I shall be only too thankful to be supplied with any of the other species enumerated by Dr. Regel. It is quite lamentable to think that such numbers of lovely hardy bulbous plants should be so completely neglected. Syria, Persia, Armenia, Palestine, the Crimea, Ionian Isles, Greece, and many another Oriental lands, teem with *Scillas*, *Croci*, *Muscari*, *Hyacinthi*, *Sternbergiæ*, *Ixiolirions*, *Tulipas*, *Fritillarias*, and many other lovely bulbous gems which ought to deck our gardens, and gladden our eyes each returning spring. If Mr. Cook would only fill his pocket with bulbs each time he takes a party to the east, and Baron Reuter would order a case of miscellaneous "oignons" to be sent home by every mail from Persia, what treasures we might some of us possess. Thanks, however, to the labours of such men as Mr. J. G. Baker, Dr. Regel, Herr Max Leichtlin, and others, we are waking up to the value of these neglected and despised jewels, and I do not despair of seeing a bed of *Tulipa Greigi* in full bloom in my little garden at Drayton-Beauchamp. I have just made up a small round bed of that lovely *Crocus*, *C. Imperati*, which I mean to leave untouched for three years, and if I may judge from the effect of a bed of *C. vernus* var. *Sir Walter Scott*, treated in a similar way, my eyes will be gladdened by a marvellously lovely sight. If I had a garden large enough, I would have a small bed of every species of *Crocus* I could procure, vernal and autumnal. When the morning sun shines out bright, their beauty is passing strange. Since I wrote this I have procured *Tulipa Julia*, *T. Celsiana*, and *T. altaica*.—H. HARPUR CREWE, Rector, Drayton-Beauchamp, Tring.

Hardy Plants now in Bloom.—On paying a visit to the interesting garden of Mr. Atkins, at Painswick, on January 27, I saw in flower in the open ground, the following plants:—*Tropæolum pentaphyllum*, *Pyrus japonica* fl. pl., *Jasminum nudiflorum*, *Crocus Imperati*, *C. Cloth of Gold*, *C. biflorus*, *Galanthus Imperati*, *G. nivalis*, *G. plicatus* (just opening), *Primula denticulata* (very fine), *Myosotis dissitiflora*, *Helleborus niger*, *H. colchicus*, *H. abchasicus*, *H. orientalis*, *Eranthis hyemalis*, *Erica carnea*, *Aubrietia purpurea*, *Iberis sempervirens*, *Cheiranthus præcox*, *Anemone blanda* (just coming out), *Cyclamen ibericum*, *C. Coum*, *C. vernum*, *C. Atkinsii* (and several varieties all in perfection), *Primroses* of several vars., including a blue *Polyanthus*, a very fine yellow *Oxlip*, double white and lilac, &c., *Hepaticas* (blue and double pink), *Arabis albida*, *Claytonia sibirica*, *Saxifraga Rocheliana*, and *S. Burseriana*. The last-named *Saxifraga* was one of the most beautiful Alpine plants I ever saw, and, being a very rare and difficult one to grow, gave more pleasure, both to Mr. Atkins and myself, than anything else in the garden. It is a dense-growing tufted species with hard leaves and large white flowers; the calyx is hairy, and of a reddish-brown colour; and the bright yellow anthers are very conspicuous; the whole plant in flower does not exceed 3 inches in height. The list of plants I have given, amounting to thirty-five species, shows what a variety of flowers may be had in the dead of winter by those who love them, as Mr. Atkins does. Would there were more like him.—H. J. ELWES.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Iris stylosa.—I send you a bloom of this *Iris*, the first we have had this season, though several more are in the bud state.—T. S. WARE, Hale Farm Nurseries, Tottenham. [A charming winter-flowering *Iris* with beautiful purplish-lilac flowers streaked with orange.—Ed.]

Planting Ixias Sparaxis, &c.—Now is the time to plant *Ixias*, *Sparaxis*, *Babianæ*, and similar Cape bulbs, which, unless planted early, do not bloom in such perfection as they otherwise would do. They should be planted in rows across 4-feet beds, 2 inches deep. Dig up the soil in the beds loosely, and on no conditions trample on it, and some rough sand should be strewn in the notches under and over the bulbs at planting time. The sand is not only beneficial to the bulbs, but it is also useful in showing where they are at lifting time, when, from being so small, they are otherwise often overlooked.—F.

THE INDOOR GARDEN.

ECHINOCACTUS MYRIOSTIGMA.

THIS may be described as a civilised Cactus, inasmuch as it has laid aside its spines and other asperities, and put on an elegant attire, bespangled with silver. This little Mexican gem has generally five deep angles, though sometimes they number seven or eight; at the apex, on the margins of the angles, are borne a quantity of silky, yellow, star-like, sessile flowers, which open during sunshine, and close about four o'clock in the afternoon. They keep expanding for four or five days in succession, according to the intensity of the sunlight, and they last longest when least exposed; the blossoms begin to open in June and continue expanding, at intervals, until October, during which period a good plant, such as that represented by the accompanying illustration, will bear from ten to twenty blossoms, $1\frac{1}{2}$ inches in diameter. The ground colour of the plant is dark green, and its whole surface is thickly and regularly beset with white star-like scales, which give it a very beautiful appearance, especially under a microscope. Its culture is in no way different from that under which other Echinocacti thrive, but it must not be subjected to a temperature below 40° , otherwise it will be sure to suffer more or less from cold, and will not flower satisfactorily. J. CROUCHER.

WINTER ORCHIDS.

WE have just seen a very fine display of these beautiful plants in the Royal Exotic Nursery, at Chelsea. The chaste flowers of *Odontoglossum Alexandræ*, of snowy purity contrasted with the rosy-flowered crimson-lipped *Lælia anceps* and the vivid orange-scarlet flowers of *Sophranitis* and *Ada aurantiaca*, would alone make a show, apart from the scores of other choice species here, growing under a few feet of glass. The pearly-white *Lycaste Skinneri* looked whiter beside the deep crimson-blotched lips of other varieties belonging to the same species, while the unavoidable stiffness of Orchids *per se* was admirably corrected by the judicious introduction of choice Palms of feathery lightness.

Everyone who requires a very choice assortment of cut-flowers nearly every day during the winter months, will find a small collection of the best winter-blooming Orchids very useful. Many of the best of all winter and early spring-flowering Orchids are amenable to cool treatment, while all are easily grown, if ordinary care be taken in their every-day management. Many of the finest of all Orchids may be grown in an ordinary plant-stove, although, for the convenience of management, they are certainly better in a structure to themselves, if only for convenience sake. Cut-flowers of the Orchids now form a distinct and striking feature in the daily supply of flowers sent to Covent Garden Market, while all the best bouquets contain a few choice flowers of *Oncidiums*, *Odontoglossums*, and other species equally valuable. We append a short descriptive list of the best of the common species, all of which may be grown for their supply of winter flowers.

CÆLOGYNE CRISTATA.—This is a well-known Indian Orchid, found on the hills of Nepaul, and having plump glossy two-leaved pseudo-bulbs, and pendulous spikes of five to seven snowy-white flowers, with a blotch of pale yellow on the boat-shaped lip. It is one of the most profuse-flowering Orchids in cultivation; well-developed specimens, grown either in pans

or on blocks bearing about 100 spikes each. The finest plants in this country are grown by Mr. R. S. Yates, of Sale, Cheshire, who grows them in an ordinary partially-shaded plant-stove, in company with Gardenias and other choice cut-flowers. The plant grows well in fibry peat, thoroughly well drained, and the bases of the bulbs should be elevated above the margin of the pot or pan. It requires a plentiful supply of water when growing, and should never be allowed to become dry enough to shrivel. As a winter-blooming plant it is unsurpassed, and its free habit of growth makes it a general favourite. A specimen, bearing ninety-seven spikes of flowers; many having seven flowers each, was exhibited, from the Duke of Devonshire's gardens at Chatsworth, in 1868. This plant was growing on a block.

LÆLIA ANCEPS.—This is another free-flowering species, having thick one-leaved pseudo-bulbs, of a glossy green colour. It produces tall two-edged spikes of flowers, 3 to 4 feet high, and is very showy when in bloom, which lasts a considerable time in perfection. The sepals and petals are of a bright rosy colour in the throat, streaked with lake, and tipped with a broad blotch of dark velvet-like crimson. It bears from three to seven flowers on a spike, and deserves general cultivation, even by amateurs, whose appliances are limited.

ODONTOGLOSSUMS.—There are several showy species of this genus that flower most profusely during our winter months, and, as most of them are amenable to cool treatment, they are doubly valuable to those whose facilities for heating are not of the best description. *O. Alexandræ* is, perhaps, the best of the winter-flowering *Odontoglossums*, and bears gracefully curved spikes of snowy-white blossoms, 2 to 3 inches across, each spike bearing twelve to eighteen flowers. Different individuals vary in their tints and markings; indeed, this variability constitutes one of their principal charms. *O. grande* bears five to eight yellow flowers blotched with brown, each being 6 to 8 inches across. It is easily grown, but requires an intermediate temperature to do it justice. It is one of the most showy winter-flowering Orchids we have, and deserves general cultivation as a decorative plant. It can be grown well

Echinocactus myriostigma.

in any ordinary warm greenhouse or plant-stove. *O. pulchellum*, a pretty little species bearing pearly-white flowers, is very valuable for cutting, and well-grown plants bear twenty or thirty spikes of flowers. It does well with cool treatment. There are many other species of this genus that bloom very freely during the winter and spring, all more or less beautiful. *O. gloriosum*, *O. tripudians*, *O. blandum*, *O. Lindleyanum*, *O. roseum*, *O. Insleayii*, and many others may be included in collections for the sake of variety if required. *Odontoglossums* grow best in small well-drained pots, and a fresh open compost of living Sphagnum and fibrous peat, with the addition of a few handfuls of crocks and dried horse-droppings, suits them admirably. All the species like a humid atmosphere and abundance of tepid water at the root when growing.

PHALENOPSIS.—These may be considered the most beautiful of all Orchids, and, as they come from the warmest and most humid parts of the earth's surface, they require a corresponding degree of heat and humidity when cultivated here at home. Nearly all the best species of this charming group may be termed universal bloomers, and their chaste flowers are specially valuable during the dullest parts of the year, either for cutting for bouquets or general purposes of decoration. *P. grandiflora*, *P. amabilis*, and *P. Schilleriana*, are the best species for winter-

flowers, and, if half-a-dozen plants of the first-named species be well grown, there will be little want of a good supply of pearly moth-like blossoms. They grow well either in well-drained pots, or on flat blocks suspended from the roof, or on the sides of a partition near the light. For small plants, blocks are preferable to pots, and when the plants get too large for the blocks they need not be removed, as much injury would probably ensue. The best plan is to partially imbed the block in a pot of fresh open compost. They require a liberal supply of moisture when growing, and should never be quite dry at any season of the year, or a loss of one or more lower leaves will follow such neglect. Within the last few days I have seen some beautiful spikes of flowers on *P. grandiflora*, *P. amabilis*, and *P. Schilleriana*, and these may be considered most useful for general cultivation.

SOPHRONITIS.—There are two or three species of this genus, all beautiful, but *S. grandiflora*, *S. coccinea*, and *S. violacea* are the best. The first-named is one of the brightest winter-flowering plants in cultivation; its brilliant scarlet blossoms contrasting very effectively with the snowy flowers of *Odontoglossum Alexandræ*, *Phalaenopsids*, and other white-flowered species. These plants may be grown either on blocks or in pots in a cool house, and flower most profusely in December and January, lasting a month or six weeks in perfection. They grow well in the compost recommended for *Odontoglossums*, and should be suspended near the light, as their flowers come much brighter in such positions. *S. violacea* somewhat resembles a *Barkeria*, and bears lilac flowers on an erect spike.

TRICHOPILIA SUAVIS.—This is a well-known Orchid, easily grown in any plant stove, and remarkable for its profuse flowering qualities. In well-grown specimens the flowers form a perfect wreath around the base of the flattened one-leaved pseudo-bulbs. Its flowers are borne three to five together, on a short drooping spike, and are of a crystalline whiteness, spotted with faint rosy-lilac, and delicately scented. It is one of the easiest grown of all Orchids, and, as it may now be obtained for a few shillings, it should be grown in quantity so as to produce a succession of its delicate and fragrant flowers.

DENDROBIUM.—This is a well-known genus, and several of its species are welcome for the profusion of their winter blooms. *D. nobile* is one of the best of all winter-flowering Orchids, as it rarely fails to cheer us with a most abundant supply of its rosy-lilac crimson-blotched flowers. It may be grown to perfection in any ordinary plant-stove, and, where a dozen or more plants are grown, it may be had in flower for three or four months of the year. In order to do this the earliest plants require a little gentle forcing, and the treatment required by *Azaleas* and other forced shrubs suits them admirably. Fine specimens of this plant, like those at Chatsworth, where it is much appreciated as a winter-bloomer, are 3 to 4 feet in diameter, and are literally one mass of flowers. In the Pine-apple Nursery, and other places in the Metropolis, this plant is largely grown for cut-flowers, and these come in very useful for bouquets, flat vases, button-holes, and dinner-table decorations of all kinds. The plant is readily propagated by division, and does well in fibrous peat, crocks, and living *Sphagnum*. Some of the rarer species are well worth growing, although few flower so profusely as the last-named. *D. heterocarpum* bears pale sulphur-yellow flowers, most delicately scented, like Violets, and is a general favourite with many ladies on that account. *D. crassinode* is another pretty species, having curiously knotted pseudo-bulbs and white flowers, blotched with yellow on the lip, while its sepals and petals are tipped with lilac-purple. *D. japonicum*, *D. transparens*, and several other species, may be added for variety.

BARKERIAS.—Two or three species are well-worth growing for winter-flowers, one of the best being the new *B. Lindleyana* var. *Centeræ*, recently imported by Messrs. Veitch. This bears flowers as large as those of the summer-flowering *B. spectabilis*, the sepals and petals being of a bright rosy-lilac, while the oblong lip is crisped at the margin and bears a deep purple blotch at its apex. It appears to be a very strong grower, and is, certainly, a most profuse bloomer, a small plant on a block an inch or two in length having borne two fine spikes, each bearing nearly twenty flowers. *B. Skinneri*, and its variety "superba," are well worth general cultivation

for their deep claret-coloured flowers, borne very freely on erect spikes, 12 to 16 inches high. Like the last, it does well on a block, but large clumps may be grown in pans suspended near the light.

LYCASTE SKINNERI.—This plant is of remarkably easy culture, and so hardy in constitution that it may be placed in a drawing-room for several successive weeks when in flower, without incurring the slightest danger of its being injured, provided always that frost is excluded. Mr. B. S. Williams, author of the "Orchid Grower's Manual," one of our ablest Orchid growers, speaks very highly of this beautiful and variable plant as a drawing-room ornament. The different varieties of this species vary from pure white to the deepest rose-coloured flowers, having a richly crimson-blotched lip. In the Royal Exotic Nursery at Chelsea, I recently noted a deep rosy-petalled flower, with a lip of the purest white, and the effect of this flower was very striking, although, of course, nothing when compared with the pure white variety itself—*L. Skinneri alba*. This species grows freely in fibrous peat, on a well-drained bottom, and should be liberally supplied with tepid moisture when growing, and at no time should it be actually dry at the root. Some growers allow its pseudo-bulbs to shrivel in order to induce it to flower freely; this practice, however, only serves to weaken its energies, and, consequently, has a contrary effect in the case of *Lycastes*, all of which bloom most freely when well grown. We have seen plants, in ordinary 32-pots, bearing from fourteen to twenty flowers each, and when seen in this state, the plants are very ornamental and invaluable during the dull portion of the year for conservatory or drawing-room decoration. This species is so easily grown, and its period of flowering extends over such a lengthened period, that it should be included in the list of every amateur who has a liking for Orchids.

CATLEYAS.—Of all the species, *C. Trianae* is the best for the purpose above indicated, and those who love variety in a really good thing may here indulge their taste to its fullest extent. The many varieties vary in colour from snow-white to the deepest rose and crimson. A few years ago (1870) Messrs. Low and Co. introduced a splendid batch of white-petalled varieties of great size and substance, and some of these have lips of the deepest velvety crimson, the brilliancy of which is much enhanced by the broad white segments with which it is surrounded. All the innumerable forms of *C. Trianae* are profuse bloomers, and deserve to be grown in quantity wherever choice cut flowers are required for the drawing-room vases. All the *Cattleyas*, if we except *C. Dowiana*, grow well in a warm greenhouse, and prefer a compost of tough fibrous peat, crocks, and fresh *Sphagnum*. Care must be taken to use small pots, as much injury often results from over potting. Elevate the plant slightly above the rim of the pot, and see that it is well drained. *Cattleyas* require a humid atmosphere, with abundance of air during fine bright weather. Water freely when growing, and, if possible, induce them to root during the dull portion of the year. Great care must be taken not to check them when growing by any irregularity, either in temperature or moisture, for, if this is done, the plants often break again from the base, thus making two growths instead of one, and neither of them have strength to bloom. *Dendrobes* and *Cattleyas* are often seriously weakened in the manner above described, and, in nine cases out of ten, this is the result of irregular treatment.

F. W. BURBIDGE.

HYBRIDISING ZONAL PELARGONIUMS.

(ORIGIN OF THE DOUBLE VARIETIES.)

IN raising from 3,000 to 5,000 seedling Zonal Pelargoniums yearly, with the view, to some extent, of obtaining novel colours, and greater perfection in the form of flowers, my special desire and aim has been to ascertain, if possible, the influence borne by the respective parents, as regards the transmission of properties to, or the production of new qualities in, their offspring; consequently, a considerable proportion of my seedlings have resulted from experimental fertilisation directed to this object only. I, therefore, derived much pleasure from the perusal of M. Jean Sisley's letter concerning the origin and production of the double varieties; the latter bearing upon the subject of my experiments, and confirming my experience, upon the prepotence of the male parent, which is at variance with

the pre-conceived notions of florists, and also denied by experienced raisers of novelties in the *Pelargonium* family. I am at a loss to account for the colour in the case of Aline Sisley being derived from the female parent. I should like to know if this was an isolated result out of many seedlings from the same cross? Also, whether M. Sisley has found that white varieties are more powerful in transmitting their colour to their progeny, than varieties of other colours; for, in crossing pinks upon whites I obtained a preponderance of white seedlings, whites upon scarlets produce salmon or scarlets blotched or streaked with pure white, white upon pinks mostly pure whites; it seems to me that white varieties are tenacious of reproducing white, and do not blend so much as other colours. There are one or two points in reference to the origin and connubial affinities of the varieties named by M. Sisley, as having been employed by M. Lemoine and himself, in the production of the double varieties, upon which I should much like to be furnished with information. The first double variety, M. Sisley states, "was found growing at Clermont-Ferrand." How that variety came there, and whether it originated from a sport or as an accidental seedling, I conclude is not known. It was stated to me, on what seemed good authority, that the doubles first imported to us from the Continent originated as sports from Beauté de Suresnes; but, according to M. Sisley's statement, M. Lemoine raised them from that variety and the pollen of the one found at Clermont-Ferrand, which suggests another point upon which I am very desirous of obtaining information. As these varieties were produced by fertilisation with Beauté de Suresnes, has either M. Sisley or Lemoine been able to cross these varieties with the ordinary Zonals? Also what relation to these, or from what origin, did the variety M. Sisley used in fertilising Madame Vaucher come? I ask these questions because, although I have tried hundreds of times, I have never succeeded in obtaining seed either from Beauté de Suresnes, crossed by an ordinary Zonal, or from an ordinary Zonal crossed by Beauté de Suresnes, and it has always been found impossible to do so by many experienced cross-breeders in England. Although I was the first to publish this fact, and, at the time of my doing so, it was noticed by Mr. Charles Darwin, and considered to be a point of great importance and interest, as bearing upon the subject of the formation of species, by his correspondence he seemed to think it possible that this variety, or a variety or two, might have diverged gradually from their ancestors in certain properties, and had come to a stop, retaining and perpetuating the acquired properties, fertilising with each other, but ceasing to become fertile with the varieties from which they had originally sprung, and so formed what is termed a distinct species. I should state that I found that Beauté de Suresnes was fertile with one old variety, known by the name of The Duke of Cornwall, which variety possesses a most decided zonate foliage; in fact, it has a darker and broader zone than any variety I have ever seen. Neither it nor Beauté de Suresnes differ in appearance from the ordinary Zonals, with the exception of being of unusually robust habit of growth. The Duke of Cornwall is also unfertile with any of the ordinary Zonals, but both it and Beauté de Suresnes are fertile with the double varieties first imported. I could not, by the aid of the microscope, perceive any difference in size or otherwise in the pollen granules of these varieties and the ordinary Zonal pollen, and am utterly at a loss to conceive why they should not cross. As Beauté de Suresnes came from the Continent, perhaps M. Sisley can give some account of its origin; and M. Sisley will also see my reason in asking for the origin of the variety he crossed upon Madame Vaucher, believing that, if it has sprung from the Beauté de Suresnes strain, he could not have effected it. Mr. Laxton, of Stamford, has raised some fine double varieties belonging to the ordinary Zonal class; but I am ignorant of the origin of his strain—whether he originated it, or whether it came from the Continent. Probably it did, and is of the same strain as the variety from which Aline Sisley was obtained. All these points would interest me much to know, and, doubtless, many who are working in the same field of inquiry.

JOHN DENNY.

Stoke Newington.

Growing Terrestrial Orchids without Soil.—The Editor of the *Irish Farmers' Gazette*, in a recent number, says:—"Every one, who knows anything of Orchids is, of course, aware that most of the epiphytal section may, in our plant-houses, if the atmospherical conditions be favourable, be grown with a certain amount of success on blocks or branches of wood, or on earthenware imitations of them. They must be also familiar with the fact that, when grown in pots their roots appear to eschew the body of the soil, and cling with tenacity to the sides of the pot, or the fragments of potsherds which form the drainage. It was from observing this, very probably, that Mr. Sayers was led to have recourse to his somewhat anomalous

potting material. The pot is simply filled with roughly broken potsherds, occasionally mixed with a few lumps of charcoal. On these the plant was placed and made firm, and the surface coated over with fresh-growing Moss, *Hypnum proliferum* or similarly-habited species. To this new pasturage the plants soon took most kindly and sent abundance of healthy roots to revel and rejoice in what appeared to be a most congenial medium, and the whole collection soon began to assume a new and healthy appearance. It is not every one, however, who would think it possible to grow and flower the members of the terrestrial section without soil; and yet, at Rockville we have seen such things as *Bletia Tankervilleæ*, *Calanthe veratrifolia*, *Phajus maculatus*, *Peristeria*, and *Cypripediums* quite at home, and some of them flowering, and apparently growing, in their light and airy medium, as well as if their roots were luxuriating in a rich compost, the ingredients of which had been selected and prepared *selon le règle*."

A Blue Pelargonium (?)—In the garden, of which I had charge in 1872, there grew in one of the herbaceous borders a fine plant of *Geranium pratense*. I am perfectly sure that there was not another plant of that species within a circuit of many miles. With the view of hybridising this plant, and thus raising hardier varieties than our common Zonals, and with better flowers than those of *G. pratense*, I commenced to operate on it. I cut off every flower-spike but one small one, and as the flowers on this spike opened I removed the anthers before the pollen grains were ripe with a pair of forceps. Then, when the pistil was in a suitable condition, I fertilised it with various greenhouse kinds of Zonals, and in every case a seed pod formed and ripened. I then sowed the seed, which germinated quickly and grew freely. The seedlings had the foliage of *G. pratense* and its herbaceous character, and owing to that I lost them, as one of the men threw them out during the winter. If any of your correspondents who disbelieve that crosses in this way can be effected will try the experiment, they will soon be compelled to alter their opinion.—JAMES SIMPSON. [We should like to see more exact proof than this that a cross was effected.—ED.]

How Lily of the Valley is grown for Market.—When a market gardener pots his Lily of the Valley, he puts as large a clump of crowns into each pot as he possibly can, and if these come up well, the shoots, are, as a matter of course, too thick; as he finds that he gets as much money for a moderately and regularly filled pot-full of this favourite plant as he does for a thickly filled one, he thins his pots of all superfluous crowns when the shoots are about 3 in. in length and have formed their flowers, removing them with as many roots as he can. The pots being still well filled, have their surface soil settled a little, and are replaced in warm quarters to develop their flowers and leaves properly. The thinnings are likewise potted, and otherwise treated in the same way as the others, but they never make nice specimens, as they fail even to produce a single fresh rootlet, the sole aim for potting them being that they may develop a few flowers that come in well as cut blooms, of which an abundance may now be seen, amongst other early flowers, in Covent Garden Market.—F.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Pelargonium Bowkeri.—Can any of your correspondents inform me where I could procure plants of this *Pelargonium* (true), which is said to have yellow flowers?—J. S.

Winter-flowering Fuchsia.—The correspondent who sent us the other day specimens of a rare Fuchsia to be named, will greatly oblige by sending us his address, which we have mislaid.

Calanthe curculioides.—This rare and showy Orchid has just flowered in the East Indian house, at Kew. It bears erect rigid spikes of deep orange-yellow flowers, and is, so far, quite distinct from its congeners, nearly all of which bear snowy-white or pale purple flowers.—B.

Solandra oppositifolia.—This is figured in the "Botanical Magazine" for this month, under the name of *Fagraea zeylanica*. It comes from Ceylon, and is one of the handsomest species of a fine tropical Asiatic and Polynesian genus. Its flowers, which are white, large, and showy, are borne in terminal clusters, and the foliage, which is ample and deep green, sets them off to good advantage; altogether it is a handsome indoor shrub.

Double-flowered Cinerarias.—These, which were first raised by Messrs. Haage and Schmidt of Erfurt, about six years ago, are now grown in their nurseries in every shade of colour in which the single Cinerarias are found. The raising of these double-flowered varieties was a very important gain for our conservatories, as, with all the variety and beauty of colour of the single-flowered kinds, they continue in bloom for a very considerably longer period than the latter do.

The Double Tiger Lily.—It may interest some of your readers to know that I saw upwards of two dozen plants of this Lily planted out last summer in the conservatory of the Jardin d'Acclimatation, Bois de Boulogne, Paris. The plants in question were flowering freely and had a brilliant effect, being planted on a cool fresh bed of *Selaginella hortensis*, which is one of the best of all plants with which to surface beds and borders in cool conservatories of the natural style. I can fully corroborate all you have said respecting this effective bulb, and hope to see it plentifully distributed, and, as it is, of course, perfectly hardy, it will make an effective plant in outdoor beds or borders, as well as those indoors.—J. S. JAMES, *Sydenham*.

THE LAWSON NURSERIES, EDINBURGH.

Our leading nurserymen have proved their right and title to take rank among our merchant princes. The amount of capital embarked in their undertakings, the energetic spirit in which those enterprises are carried forward, and the various kinds of knowledge required in order to ensure the successful prosecution and management of such pursuits, undoubtedly place the profession of a leading nurseryman in the first rank of commercial enterprise. Every successive horticultural season, with its magnificent fruit and flower shows, which continue uninterruptedly to increase in extent and importance, are attracting larger and larger numbers of the general public to take a lively and intelligent interest in plant and tree culture, whether as means for increasing the beauty of our parks and pleasure gardens, or for the realisation of improved and extended crops of culinary vegetables and table-fruits. Scarcely forty years ago, only a few horticultural enthusiasts, supported by a very small and straggling band of lukewarm amateurs, could be cited as true patrons of horticulture; and it was not till such men as Lawson, Knight, Perry, Veitch, and others, whose names deserve equally honourable mention, had, by their enterprise and success, thoroughly aroused public attention, that the present wide-spread interest in their important vocation was firmly established. It was their boldly speculative importations of valuable and beautiful novelties, and their interesting experiments and improvements in various modes of culture, that created the present highly advanced state of the national taste in matters horticultural, and, in many instances, even a passionate love of their pursuit. By the unflagging energy of such men, and that of their collectors, aided by the labours of other explorers, the earth is being ransacked, so to say, in its entire circuit, in pursuit of its hitherto unknown vegetable treasures; and scarcely a year now passes unmarked by the exhibition of some new and valuable flower, to be gazed on for the first time by European eyes; some new and graceful Pine from the mountain recesses of California; some new fruit, as a delicious addition to the delicacies of the table; or some new root, grain, or Grass likely to become of practical value to our rapidly increasing population.

Among the first who stepped boldly out from the previously humble position of the routine nurseryman, was the ancestor of the late Messrs. Lawson & Son, whose extensive establishments have been recently purchased by a company (in January, 1873) which intends to prosecute vigorously the various enterprises which they have thus taken up. The energetic character of Mr. Peter Lawson, the founder of the house, may be partially estimated by his spirited advertisement in the *Caledonian Mercury*, of November 21, 1780, nearly a century ago. Among a goodly list of trees, roots, and seeds, we find, in the paragraph devoted to bulbous and tuberous-rooted plants, "a large assortment of Turkey and Persian Ranunculuses," announced as "imported direct from Holland;" that beautiful tribe of flowers being then scarcely known as hardy garden flowers, even to the most advanced English florists and amateurs of the time. In the same advertisement he announces the arrival of "a very large assortment of fruit trees," from the celebrated nurseries at Brompton Park, as just received by the good ship the *Lovely Mary*; and he further states that by the *Jemima* and the *Mary*, both of the port of London, he has also received other kinds of nursery stock, including garden and agricultural seeds, the newest kinds of gardeners' and farmers' tools of all kinds, and many other articles connected with horticulture. In his nurseries he was eminently successful in raising forest trees of all kinds in immense quantities, from seed, which he duly announced as ready for sale, either as seedlings, or once or twice transplanted. One may easily imagine, conducting his enterprises with this amount of genuine earnestness, that he succeeded in founding a very extensive business, far in advance of that of most other contemporary establishments of the kind either in England or Scotland.

When, in due course of nature, the concern thus established by the father passed to the son, in 1821, the late venerable Mr. Lawson found himself, while still in the prime of life, in possession of a great and thriving business, in a condition of rapid expansion, which his superior knowledge and energy soon

made still more important and valuable. In the very beginning of an independent career he introduced several new and valuable trees; among others the valuable *Pinus austriaca*, the robust hardiness of which, in addition to its other attractions, renders it extremely useful as a nurse, or rather shelter, to young plantations of more tender trees. Every branch of the business, in short, received a new impetus under the skilful and energetic management of the new head of the firm. He laid himself out especially to give a vast extension to the agricultural seed department; which, under such management, soon assumed dimensions which might appear incredible to such as are not acquainted with the vast scale which this branch of commerce has assumed. The Messrs. Lawson paid much attention to Grasses, and the kind of land to which they were respectively the best suited to produce heavy and succulent crops of herbage—and succeeded by careful and long studied selection in discovering profitable kinds for culture in almost every kind of situation. It was in 1833 that Peter Lawson & Son made the valuable addition of the *Lolium italicum* to our list of cultivated Grasses; a plant which cannot be over valued both as herbage and forage, and for its profuse growth. The work entitled "*Agrostographia*," produced and published by them in 1842, is an elaborate treatise on cultivated Grasses and other herbage and forage plants, such as Clover, Trefoil, Lucerne, and others, which have been called artificial, as distinct from natural Grasses. It has proved extensively useful to landowners and farmers, and has gone through five editions, printed at the Lawson press. The work (founded on many detached essays) first appeared in a collected form in 1842, and the fifth edition was issued by the authors in 1855. In this important work, the Grasses or other plants suitable to different situations and climates, and the quantity of seed to be sown per acre, are set forth with an instructive distinctness which does the authors great credit. Other important works issued from their private press, among which may be mentioned a "*Synopsis of the Vegetable Products of Scotland*," a "*Descriptive Catalogue of the Fruit Trees, Shrubs, &c., Cultivated in the United Kingdom*," the "*Agriculturists' Manual*," and, more recently, a magnificently-illustrated work on Coniferae, called the "*Pinetum Britannicum*." The Messrs. Lawson had been for several years seedsmen to the Highland and Agricultural Society of Scotland, when, in 1853, they were appointed the Queen's seedsmen for Scotland.

After having either introduced or distributed many genera and species of the cone-bearing family of trees, especially the *Wellingtonia*, and being among the first who successfully raised from seed a large stock of that magnificent tree, the crowning success of their enterprise in that direction was the purchase of the first stock of plants and seeds of the exquisitely beautiful *Cupressus Lawsoniana* of Mr. William Murray, the well-known Californian explorer, who, after a successful expedition in 1855, also discovered and brought over, for the first time, *Pinus Beardsleyi*, *P. Craigana*, *Abies Hookeriana*, *Taxus Lindleyana*, *Cupressus M'Nabiana*, and, above all, *Cupressus Lawsoniana*, so named by Mr. Murray in honour of that spirited firm, who had purchased of him the whole botanical results of his expedition at a most liberal price, after he had failed to obtain anything like a valuable offer in England. This kind of open-handed commercial generosity naturally secured for the late Mr. Charles Lawson, the head of the firm, the esteem of his fellow-citizens. He was elected Master of the Merchants' Company of Edinburgh, and became Lord Provost of the city, during which tenure of office, like the Herriots and Greshams of the past, he became the friend and host of royalty, having had the honour of receiving the Prince and Princess of Wales in his own house during their visit to Edinburgh. Such is but a short sketch of the commercial career of one who only recently departed this life at the ripe age of seventy-nine years. The Company which has taken over his vast business in all its branches, intends to carry it on in a spirit worthy of its founders, and with the large capital at their command, aided by an able staff of officials, many of them experienced *employés* of the late firm, will, no doubt, be eminently successful in their great undertaking.

I recently explored the vast warehouses at George IV.

THE LAWSON COMPANY'S NURSERY, EDINBURGH.

Bridge, and likewise their nurseries in the suburbs, and all I saw distinctly bore the impress of energy and success. On entering the nurseries the finely laid out and richly planted flower garden, backed by a selection of ornamental evergreens and other shrubs, forms a very charming *coup d'œil*. Here are displayed a number of novelties, many of them raised by the company or their predecessors, a glance at which is enough to rouse the most sluggish admirer of the beauties of nature into becoming at once an enthusiastic florist. In the greenhouses were three new varieties of the large-flowered Clematis family, all perfectly hardy. The variety named Lawsoniana had several flowers measuring fully 9 inches across, the eight petals being of a delicate rosy-purple veined with red. *C. Henrii*, with flowers of a creamy-white, is remarkably beautiful and delicate, and Symeana, with flowers of soft pale mauve, exhibited blooms nearly as large as those of Lawsoniana. All the families of ordinary greenhouse and garden flowers, both shrubby and herbaceous, were extensively represented, but important as this branch of the business has become, it is the finer kinds of forest trees, especially those belonging to, or allied to, the Fir tribe, that have always formed the grand staple of the Lawson Nurseries. In the department of Coniferæ, all the kinds worth growing are raised in large numbers, from the smaller kinds of ornamental lawn shrubs, to the noblest foresters of the family; from Larch, Scotch Fir, and Norway Spruce, to the giants of the Californian forests. To convey some idea of the extent to which the production of the commoner and hardier species of the Fir tribe is annually carried, such as Larch and Scotch Fir, for instance, it may be stated that I found several millions of young seedling Larches ready for sale, the demand for which is such that scarcely a sufficient supply will be left in stock for transplanting and forming one and two year-old plants, and to produce this number of growing Larches, over 2 tons of Larch seed are annually sown. Other trees are grown upon a corresponding scale, though scarcely, perhaps, to be counted by millions; but there are acres on acres of various kinds of Chestnuts, Oaks, Ashes, Elms, and Maples, both for forest use and for ornamental plantation, the variegated varieties being sedulously developed to meet the prevailing taste. Among the large collection of trees and shrubs specially cultivated for their variegated foliage, I noticed one of the dog-woods, *Cornus mascula variegata*, which is superior in the striking character of its white maculations, even to the favourite *Negundo fraxinifolia*, and also a variegated Turkey Oak, equally remarkable; many other finely variegated trees being under experiment as to the permanency of their leaf-markings. A sort of principle seems to be pretty well established that those leaf-variations, which take the form of a border, are much more likely, as a rule, to remain permanent than those which assume the form of irregular blotchings, though, of course, there are striking exceptions. The rule was, however, well exemplified in the case of Hollies, of which a splendid series of beautiful varieties have been raised, supplies of which are generally grown from cuttings instead of grafting, by which last-named process great shoots of green foliage from the stock are so liable to occur. In order to enable planters to produce effects of light foliage in front of dark, the Sea Buckthorn, with its cinereous leaves, and the pale green Tamarisk, are abundantly grown. But, to a casual visitor, as was my case, it is the long walks and avenues, bordered with splendid specimen plants, chiefly Conifers, that present the most alluring attractions; their fine growth and endless variety of form, and the exquisite gradations of green, yellow, and brown which they display are, indeed, very fascinating. There is the grandeur of *Picea nobilis*, the towering grace of *Cedrus atlantica*, the golden hues of *Thuja aurea*, the rigid and regular growth of *Araucaria imbricata*, and the novelty both of hue and growth of the Sequoia, which form together such noble galleries of the beauties of evergreen vegetation as at once arrest the attention of the most indifferent observer; while, more beautiful than any of those alluded to is the Lawson Cypress. It was one of the trees discovered in Mr. Wm. Murray's explorations in 1855; and his brother Andrew, in his graphic description of the results of that successful raid among the magnificent vegetation of the Sierra Nevada, says, "this was the handsomest tree seen

in the whole expedition. It was found on the banks of a stream in a mountain valley, growing to the height of about 100 feet. The foliage is most graceful, and the branches hang down at the tip like an ostrich feather, while the top-shoot droops like that of Deodar." It is well to note these features, so graphically described by Mr. Murray, which form the chief characteristics of the tree in its own region, because many of the plants raised from seed in this country vary so remarkably as occasionally to lose entirely the natural character of the tree. Those seedlings, therefore, which exhibit the true and original type should, as a rule, be selected; though several extremely pretty varieties are well worth preserving. Beautiful as are the splendid specimens of this tree as grown in the Lawson Nursery, we can as yet know little of the noble aspect it will assume when it shall attain its full dimensions of 100 feet in height. It will be for the children of those who are fortunate enough to secure some of the largest and finest specimens now obtainable in England or Scotland, to see this grand addition to our recent acclimatised Coniferous plants in all its magnificence.

In order to convey some idea to the readers of THE GARDEN of the beauty of the walks and avenues of the Lawson Nurseries—which (by permission) form one of the more favourite promenades of the suburbs of Edinburgh—the editor requested me to select a point of view from which a drawing, suitable for a large engraving, might be taken. I have chosen one which, I believe, cannot be matched, for the vista it commands, by any nursery in Europe. The outline of the Calton Hill which terminates the landscape from the point selected, crested as it is by the Nelson memorial, by that of Burns, that of Playfair, and others, and by the grand colonnades of the incomplete national monument, looking like the commencement of another Parthenon crowning a modern acropolis, presents a combination of noble objects and a *coup d'œil* not to be surpassed, while the slight mist in which it was veiled at the time during which the drawing was taken, adds to, rather than detracts from, the beauty of a picture that can be but very inadequately reproduced by the labours of the draughtsman and the graver, be they ever so skilful.

The great warehouses at George IV. Bridge are as worthy of note as the nurseries of this establishment, though they do not admit of or require so much detail in their description. Like all the buildings in Edinburgh (even many private houses) these warehouses consist of separate flats, five in number, the principal one being devoted to the various offices of the company. Some idea of the dimensions of these flats may be conceived when it is stated that the one entirely devoted to Turnip seed is capable of containing upwards of 20,000 bushels; the arrangements for the special growth of this seed being naturally on a corresponding scale. One grower in Kent grows 200 acres of Turnips for seed for this firm, and they employ several other growers in different parts of England and Scotland. The great celebrity obtained by Messrs. Lawson & Son for root and Grass seeds, in consequence of the persistent care with which their stock has been kept true to sample, and the seed thoroughly ripened, necessarily led, with the general advance in agricultural skill throughout the country, to as extensive arrangements respecting all kinds of agricultural seeds as those named in regard to Turnip seed. It will, therefore, not be necessary to more than hint at the thousands of bales of Rye Grass seeds annually imported from the Continent in addition to that grown in England and Scotland, with many other sorts for mixing and for sowing on soils of special character, nor to refer to seeds of other kinds. It should be added, however, that the entire of the lower flat is devoted to Clover and other weighty seeds, and to the extensive machinery for dressing the Rye Grass seed, and that every part of this extensive warehouse, or rather series of warehouses (for such in reality they are, each division being fire-proof), is annually re-filled with an abundant supply of every variety required either for field or garden use. In conclusion, while endeavouring to form some idea of the great extent and importance of this business, I must not omit to state that the London warehouses belonging to this enterprising firm, in Southwark Street, are nearly as important as those in Edinburgh.

THE FRUIT GARDEN.

CULTURE OF THE RASPBERRY.

ON this subject Mr. Hobday has given your readers much sound practical advice at page 72. I wish to supplement what he has said, and also to differ a little from him. I have reasons to believe that, however deep, rich, and moist the soil may be, it requires also to be sandy or porous. The Raspberry dislikes a stiff clay soil, and, should it be strongly impregnated with iron, few things will be more difficult to thrive upon it; the plants seem to do best in a light, rich, decomposed vegetable soil. One seldom sees Raspberries doing badly in the oldest kitchen garden, if they have been only attended to. My experience goes to convince me that deterioration is the result of neglect, and not because the plant gets at last tired of the ground in which it is grown. Instead of quantity and quality being deteriorated at the end of five or six years, I should then expect them to be just coming into bearing, and to continue so, without deterioration, for twenty years at least. I should be rather loth to destroy them sooner if doing well; surely we should never treat Raspberry canes like Strawberry plants! If Raspberries are best treated in that way, Currants and Gooseberries must share the same fate. I agree with Mr. Hobday, in having the canes or plants at a good distance apart; there is no question that is far more profitable than to have them bundled together. I cannot, perhaps, do better than describe the manner in which those were grown that were considered the best that came to market in the seaside towns of South Devon; they were grown in rows, 5 feet between the rows, and 4 feet apart in the rows, the earth being a rather light sandy loam, about 2½ feet deep, with rather cold sub-soil. We will suppose the plants to be five years old. The treatment was simply this: Commencing in the autumn after the foliage had fallen, with yellow twigs of Willow tied by his side, my father would proceed to prune the canes; he never would leave more than five or six canes to each stool, selecting the largest and best ripened canes, which were the thickness of one's finger; he took half of them in each hand, opening the hands pretty wide, and going around as far off, so that the canes might begin to twist well at the bottom, keeping them in his hands and going round until they were twisted to the desired height, corkscrew fashion. At 5 feet from the ground one end of a little Willow wig was thrust into the middle of the canes; it was then twisted around for three times, and the other end also thrust between the canes; the whole of the tops were then cut off, and he proceeded to the next stool. After the pruning and tying up, next came a fair dressing of dung, this being made from the cuttings and cleaning of all the garden and vegetables going to market, and well worked about until rotten by a lot of pigs. This was then spread and dug in. It was not dug deep, only one spit in the middle, the rest merely covering the dung. At the same time a row of early Cabbage plants were planted between the rows of Raspberries. These as soon as they were sent to market, and the stumps sent to the pigs; the hoe was kept plying between them, and all suckers, except those to be left for the next year's crop, and one here and there for other purposes, were cleared away, no support as yet being employed; but as soon as the growth commenced, a stake, such as is used for runner Beans, was placed to each and tied with a Willow. As the summer advanced, and the crop swelled, the water-barrows were set going. When the fruit was all gathered, all the old canes were cut away, the stakes taken up, and stored away until the following year, the young canes were just loosely tied together to keep them from being broken, and left so that the sun and air could play amongst them; this is a most important thing. I have seen whole quarters swept away, even in Devonshire, after a wet autumn, and then a hard winter, particularly with the double-bearing varieties. Besides, the quick and simple means of getting over the work, the saving in stakes alone is such that should commend itself to all, and especially to market gardeners and amateurs. It is surprising what an enormous quantity of water, like Strawberries, they require in a dry summer. If they once get really dry, the fruit will be small and indifferent. Mulching, after a good soaking, will be of the greatest importance. By no means encourage autumn

bearing, if you wish to save the canes, or to have a crop the following summer; there is a season for Raspberries as well as other fruit: late Raspberries are of little use in autumn, they are so watery and flavourless, and, moreover, are a sure sign of little fruit the coming season, if the plant survives. We used to grow (after trying many other varieties) mostly the Falstaff, not the round variety, but a stronger grower, of the same hardier variety, and not so given to bear the autumn crop; the fruit was like a woman's thimble in size and shape. We had an early variety that was much earlier than the Antwerp, the fruit was not so long as in that variety, canes quite as strong again, of pale colour, and covered with small thorns throughout; it was quite local, and the earliest I ever met with. And now, as to growing under difficulties—in shallow, dry, poor ground, Raspberries do but indifferently, consequently it is best to grow them in trenches, to afford them a better chance of being supplied with moisture, both natural and artificially; the best way is to have trenches taken out two feet wide, and one deep, and, if necessary, take out some of the sub-soil, if not deep enough without it; place in this trench 6 to 10 inches of good rich vegetable soil, from the rubbish heap, for instance; place the plants on it, cover the roots with the same; place a little of the surrounding soil over this, but leave the ground between the rows at all times the highest. Although Raspberries love moisture, there is poor chance of success in cool, wet, clay soils; here, then, plant on the ridge instead of in the furrow, proceeding thus:—Have the ground well trenched and well manured, set the line in its place, have one man to hold the plant in its place on the surface, while another places a good coat of the aforesaid compost over its roots, then throw up the earth from the middle on each side, and keep it so ever after, merely forking the sides, and giving a good coat of dung annually.

Maesgwynne, Whitland, South Wales.

JOHN TAYLOR.

Gumming in the Kaisha Apricot.—I was induced by the favourable opinion of the Kaisha Apricot, expressed in your paper of August 16, to order some trees of it from my nurseryman, and, although it is too soon to express any decided opinion as to the merits of the tree, I must own to considerable disappointment in reference to the "gumming" in the branches, from which it was said to be comparatively free, but, in my short experience, this is by no means the case. —C. E. [Mr. Tillery, of Welbeck, the writer of the article in question, and to whom your remarks have been submitted, says: "I expect the trees which your correspondent ordered from his nurseryman were young, and, being planted only last autumn, the nails used in fastening them to the wall wounded the bark of the gross young shoots, thus causing the "gumming" of which he complains. All kinds of Apricots, Peaches, and Cherries, will gum when young, if the nails used for fastening the shreds are so close to the wood as to injure the bark. I have a collection of all the best known varieties of Apricots on a south wall, 850 feet in length, and amongst them are many trees of the Kaisha, of a good size, and without ever having lost a branch from canker or gumming. It is different, however, with the Moorpark, and some other sorts, for some large branches, every other year, mysteriously canker, and have to be cut out. The soil here is very suitable for the Apricot, being of a turfy character, brought from a magnesian limestone rock, and the sub-soil is concreted and well drained. The Kaisha is a variety which ripens a little earlier than the Moorpark; it is smaller than that variety, but equally good, either for preserving or for dessert; I, likewise, have found it to set better in the last two bad Apricot seasons than any other variety which I cultivate."]

Packing Fruits for Travelling.—How to pack fruits, so that they may be conveyed in a green state through varying temperatures, has long been an unsolved problem. Mr. Carson, President of the Horticultural Society of Victoria, however, succeeded in sending to the late International Exhibition at Vienna fresh Apples, Pears, &c., grown in Victoria. They were carefully gathered, and each fruit was wrapped up in clean unused tissue paper. A layer of dry cotton-wool was then laid in an ordinary case, and on this a layer of Apples in paper. More cotton was rammed in between the Apples and the sides of the case, as well as between the fruits; another layer of cotton succeeded, followed by fruit as before, and so on until the case was filled. The lid was then nailed on in the usual manner, and the packing was complete. The cases were placed in the ice-room of the steamers until landed. The result was that the fruit when unpacked at Vienna was in fine condition, and excited both admiration and astonishment.

THE GARDEN IN THE HOUSE.

FERN-FROND DESIGNS.

SOME time ago we gave directions for leaf and Fern printing, and we now propose to treat of a plan by which very pretty designs may be made at little trouble and expense. Many of our lady readers may like to make designs or pictures of Fern fronds and other foliage, and a little application and manual dexterity will suffice to effect this, if the following directions are carefully followed: The materials necessary are Fern-fronds and leaves, a few sheets of white drawing-paper, or, better still, Bristol boards, a stick of common Indian ink, an ordinary tooth-brush, an ounce of small entomological pins, and a common saucer or palette in which to mix the ink. A few other little extra conveniences will be found necessary by the operator, but these will easily be supplied, as required, by a little forethought and ingenuity. In order to form a design, take a sheet of paper and fasten it securely to a flat drawing-board; if it be damped and glued round its edges, so much the better; but if Bristol boards are employed all they require is four pins at the corners. Now arrange your Fern-fronds or leaves, as gracefully as possible, on the paper, for the more neatly they are arranged the better will be the design produced. Secure the Ferns to the paper by sticking the small pins all over them, especially around the edges of the fronds, as every little lobe and pinnule must be securely pinned down to the paper, as the work of arrangement proceeds. Do not arrange one frond over another, and, when the group is completed, according to taste, proceed as follows:—Take your stick of Indian ink, and rub it with a little water in a saucer; now dip your tooth-brush into the ink, and placing the board, on which your Fern design is placed, upright against a larger board or other support, proceed to sprinkle it with the ink by drawing a pin across the bristles of the brush. This throws ink in small drops and spots all over the exposed parts of the paper not actually occupied by the fronds. By careful manipulation, a delicately-shaded effect may be obtained, and it will be noticed that, after the brush is first dipped, the ink is thrown in larger spots, and they gradually become smaller and smaller, until the brush is empty. With practice, the margin around the design can be shaded off into the white paper, so as to produce a very delicate and pretty effect. After the tint is worked on deep enough, and the whole is dry, the fronds may be removed, and the form of each will be found in white, surrounded by the tinted ink ground. A very little practice will suffice to enable any one with moderate ingenuity to make charming ornaments for screens, albums, or portfolios. By the above simple method, when well done, every little pinnule is as true in shape as in the Fern itself, and the representations thus obtained are the best of portraits. Large bold fronds or leaves are best to commence with, but the most delicate Maiden-hair and Filmy Ferns can be copied with fidelity by practice, all they require being a little more delicacy in the manipulation. If desired, the mid-rib and principal veins can be drawn in with a fine lithographic or etching pen and Indian ink after the fronds are removed. A pretty design for an album or portfolio may be made by using a bold leaf, such as that of *Ficus elastica*, Maple, or Lime, as a centre, arranging a border of Ferns around it; this forms an oblong or heart-shaped space, in which a verse of poetry may either be written or printed and illuminated. Another plan is to cut a scroll out of paper and pin it down, surrounded by a border of small Ferns, then, on removing the paper and Ferns the white space remains for a motto or text. Our readers are now in possession of the way to form very pretty designs, and one of their greatest charms consists in the immense variety of size, form, and arrangement that may be adopted according to taste. The ink employed can be varied in tint by mixing it with water colours, or the pure colours may be used alone instead of the ink. Burnt sienna or sepia gives a very nice effect, and other tints, either in water-colours or Judson's dyes, may be adopted according to taste. By employing a different tint with each group, a great variety of effect may be obtained; and, in this way, a large album might be filled with the most graceful designs, so varied in colour, outline, and expression, that no two pages would present subjects which resemble each other.

F. W. B.

THE ARBORETUM.

LONDON PLANE-TREES.

ARE you sure you are right about *Platanus occidentalis* being the London Plane? Loudon, Selby, and others, all say *P. orientalis* is hardier than *P. occidentalis*, and I always understood that the greater part of the trees in London consist of *P. orientalis acerifolia*. If this is the case, it ought to be planted in Sackville Street, Dublin; but perhaps, you have spoken from better authority. W. B. SMITH.

[Our authority is Mr. Gordon, author of the "Pinetum," who thus writes concerning the Planes in question:—All the large Planes-trees in and about London are unquestionably the *Platanus occidentalis* or American Plane, and the reason why it is considered tenderer than the Oriental Plane is, because it not unfrequently suffers severely from having its young leaves and fresh growth half killed by late frosts in May, particularly after mild winters and early springs. In all other respects it is as hardy as the Oriental Plane, as was proved by the severe winter of 1837-8, when none of the large trees in and near London suffered the least injury, although the thermometer sunk to 4° below zero. The Maple-leaved or Spanish Plane has the same spreading habit and fruit as the Oriental Plane, and never grows near so tall as the American Plane. The Oriental Plane is unquestionably the best of all the Planes, both for shade and handsome foliage; but it is not nearly so rapid a grower as the American Plane, particularly when young. It forms a round and rather dense-headed tree, seldom exceeding sixty feet in height, with a comparatively short but massive stem, which soon divides into several robust arms, the lower ones of which are the largest, and spread horizontally to a very considerable distance. The greatest difficulty in the way of planting Oriental Planes—as trees for shade along a public thoroughfare—is in getting them with stems sufficiently tall to raise, when full-grown, their lower and wider-spreading branches high enough so as not to interfere with vehicles passing under them.—ED.]

TREES IN CHURCHYARDS.

THE planting of trees about town churches, which is now becoming prevalent, is a praiseworthy renewal of a good old custom which was formerly very general around the churches of our provincial towns of the seventeenth and eighteenth centuries, when few were to be found without a spacious churchyard surrounding the structure, and in many cases this enclosure was encompassed by a broad walk bordered with trees, which frequently became a favourite promenade of the town's-people on Sunday afternoons; or when the merry chime of the morning bells attracted different classes of people at other times, more especially when the ringers were practising for a match, in the leisure hours of the evening, when the routine toils of the day were over. Tastes are not so simple now-a-days. There are few ringing matches for the exciting prize of "a leg of mutton and trimmings," and few discussions as to the merits of "triple bob-majors" now no longer form the basis of musical *réunions*. But, leaving out of the question the matter of the churchyard being made a promenade or public lounge, a state of things that, with other obsolete customs, has faded away into the limbo of the past, the planting of trees in connection with churches, wherever there is room, may be safely advocated with at least two good and sufficient reasons to back it. The first is, that the necessarily rigid lines of all architectural structures are softened and rendered more picturesque by a foreground of trees—which should not, however, be so planted as to obscure too much the work of the architect; yet none could criticise adversely such judicious planting as that of the pretty and tasteful church garden, as shown in the illustration which accompanies this article. Even the architect himself—though he might, if consulted, have objected to the hiding of a single stone of his structure—would necessarily be converted to the opposite principle if he could be shown two pictures by artists of equal merit, one displaying his handiwork bleak and bare as "Bleak House" itself, and the other showing it partially concealed by a lacy veil of foliage, casting its soft and ever-moving shades on the sculptured walls, like the shadows of scudding clouds on a fair landscape, and making shelter for a merrily-chirping choir of birds at times when church-doors are closed and the songs of the human choir are silent. Secondly, in the long lines of our treeless streets and

terraces, the greenery of a group of trees would mark the situation of the place of worship very pleasantly; and the passing beneath their branches to the church door would, to some extent, fitly distinguish it from the stony and bare approach to interminable rows of stucco porticoes. In many situations, where the aspect is favourable and the space sufficient, flowers might be added, as they are in our country churchyards, a custom which has sprung up in recent years, as part and parcel of that love of flowers and of general horticulture which has happily increased among us; and the presence of flowers thus introduced has generally tended to make the churchyard the prettiest spot in the village, instead of, as it used to be, the most dingy and desolate, when the sombre foliage of a solitary Yew, in days that are fortunately of the past, formed the only kind of vegetation permitted, except the rank Grass that half concealed the mouldering and neglected tombstones. This is still the case in many instances I could name, where the pastor is careless in such matters. The introduction of flowers is always pleasing, but it should be observed that in too many cases where the attraction and appropriate beauty of flowers near the tombs of the departed is fully appreciated, the planting of trees is entirely neglected; though recent introductions have furnished us with such a variety of trees of beautiful growth, specially suited to the purpose, such as the exquisitely beautiful Lawson's Cypress, the *Cupressus funebris*, and many evergreen trees of different families. The planting of churchyards, in short, should form a special study; and then, with the attention of some of our most eminent landscape-gardeners devoted to the subject, we should soon obtain very pleasing results. In the case of town churches, where the surrounding space is generally limited, under the most favourable circumstances, care, both in the selection of the trees and the placing of them, is very important. Even in the most confined space there is a right and a wrong place to plant a tree, and the wrong one is as often selected as the right. Our respect for the art and science of horticulture is yet very young, and we do not consult its professors as often as we should. We never think of employing any but a tailor to make a coat, nor any but a milliner to make a bonnet; indeed, we are very particular that educated practitioners of those arts should be employed in these comparatively unimportant matters; the results of both tailors' and milliners' ingenuity being flung aside within the twelvemonth; while it is but too commonly thought that any one can plant a tree—a thing that is intended to increase in beauty each year, and to endure for a century, or may be centuries. The fact, however, is indisputable that a well-digested knowledge of trees and their requirements is as necessary to a proper utilisation of their capabilities as intelligence and experience are to the successful carrying out of any other object. H. N. H.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Loquat (*Eriobotrya japonica*).—This is seldom seen in plant-houses, and yet it is neither wanting in beauty as a decorative plant, nor in utility as a fruit producer. In the gardens at Cottingham Grange, in Yorkshire, there is a compact and handsome specimen of this plant, in the form of a standard, bearing fruit in profusion in two stages, and the gardener, Mr. Cottam, assured me that it ripens three crops in a season. This fact is worthy of remembrance by those who can afford it house room, and are fond of Loquats.—G.

***Berberis vulgaris atropurpurea*.**—This is a handsome variety, with foliage which, in spring, is of a deep wine colour, passing gradually into brown, and, in autumn, becomes of a purplish-green. As the plant is most attractive in a young state, a means has been discovered of perpetuating the charms of its youthful foliage by cutting the stems down close to the ground every second year. This generally prevents the occurrence of flowers or fruit, but as the plant is valuable for the effect of its early foliage only, its flowers and fruit are well sacrificed to obtain it.

CLIMATIC CHANGES IN SCOTLAND, AS EVIDENCED BY GARDEN VEGETATION.

ONE of the chief topics (says Mr. McNab, in his opening address to the Botanical Society of Edinburgh) which has occupied my attention for many years, and the one which will form the principal feature of this address, is the difference observed in open air vegetation previous to the years 1837-38, as compared with what is seen at the present time. The observations which it is my intention to make will not be complete without much meteorological research. I trust, however, that my excellent friend, Mr. Buchan, will be induced to supply from his store of meteorological treasures the desiderata necessary to render this paper of greater importance than it can possibly be in its present shape. Many of the shrubby plants at one time familiar to the oldest members of the society, in this part of Scotland, are now rarely to be met with in the open air, and certainly not in the same state of perfection. Whether this is owing to a deterioration of our ordinary summer climate, or to the non-ripening of the wood from the want of sun-heat, it is not easy to say, but true it is that a change has taken place during the last forty or fifty years, as I shall endeavour to prove to you. Three severe winters, viz., those of 1837-38, 1841-42, 1860-61, carried off by death a large quantity of fine plants; of those killed many of the kinds were replaced, some succeeded well, while others have never since shown the vigour of stem, leaf, flower, or fruit they were wont to do in former times. To illustrate my remarks on the effects of climate, numerous examples might be quoted; a few, however, will be sufficient to explain my meaning.

Trees and Shrubs, &c.

For a considerable time, both before and after the year 1835, the *Hydrangea* used to be grown abundantly in the gardens and pleasure-grounds in this district of Scotland, producing in many cases from twenty to forty heads of bloom on each plant, according to its size. The wood ripened by the sun was usually protected during the winter with mats or Spruce Fir branches. About the same time the sweet-scented *Verbena* (*Aloysia citriodora*) also formed large round clumps, and flowered freely every year; now this plant, like the *Hydrangea*, can scarcely be got to survive long in the open air, except in some very sheltered places near the sea, and flowering is nearly out of the question. Numerous varieties of the Rock Rose, or Gum Cistus, were extensively cultivated in our gardens about forty years ago. The gorgeous bloom, and the various tints and colours

of their flowers, were always a source of interest. Now many of the varieties of these plants are quite lost to the country, and few varieties are seen in any garden, although for the west coast of Scotland the varieties of Gum Cistus ought to be admirably adapted.

About the same period the common Myrtle was seen in a vigorous condition, both trained on walls and as standards. Wall-trained specimens used to flower and fruit abundantly, but now flower and fruit are rarely to be met with, particularly in this part of the country. During the memorable winter of 1860-61, a large Myrtle was killed on the garden wall at Leuchie House, North Berwick. This plant had stood in the same position for 100 years, and flowered regularly. The examination of a section of the stem proved that this plant was exactly a century old. Along with these suffruticose plants may be enumerated *Punica granatum*, *Benthamia fragifera*, *Ribes speciosum*, *Maclura aurantiaca*, *Cupressus sempervirens*, *Aristotelia maqui*, *Photinia serrulata*, *Eriobotrya japonica*, *Azalea indica alba*, and *Ligustrum lucidum*. The *Ligustrum*, although occasionally seen in shrubberies, shows a spindly habit in comparison to what it did in former years. The *Mespilus Pyracantha* is another shrub which used to grow freely, and flower and fruit abundantly on our walls, but it is rarely now to be seen in that perfection, or in anything; like the frequency, formerly observed. The *Catalpa* tree, which used to attain to a height of 18 to 20 feet, seems fast dwindling away. The *Fuchsia*, particularly the *F. coccinea*, *F. gracilis*, *F. tenella*, and *F. discolor*, with the hybrid variety called *F. Riccartoni*, used to stand our winters well, with the exception of the two last-named, which, on this side of the island, are frequently cut to the ground, but never killed; the others are now scarcely to be met with.

A Church Garden.

A notable tree much admired in former years is the Almond, which used to produce flowers nearly as fine as those in the neighbourhood of London; our climate now does not seem to be sufficiently hot to allow it to ripen its wood so as to enable it to produce flower-buds, as most plants now seen in bloom are imported from England with the flower buds already formed.

The *Acacia dealbata* or *affinis* is a New Holland tree, which used to luxuriate in the open borders; I have seen it growing both in the botanic and experimental gardens, averaging about 26 feet in height, with stems 20 inches in circumference at the base, and frequently producing flowers. This species was also at the time standing near the rock-work in the garden of the late Dr. Neill at Canonmills. The tree was 12 feet high, with a stem 10 feet in circumference at the base. Numerous other examples of this tree were seen about the same time in various gardens in the east of Scotland. *Eucalyptus pulverulenta* is another New Holland tree which used to be an ornament on our lawns, but, like the *Acacia*, it now ceases to exist as a standard. Specimens are occasionally planted on exotic walls, but, even with the greatest care and protection, it is with difficulty that we can keep them alive for many years together. How different it is on the west coast of Scotland, where the plants above mentioned are often seen growing luxuriantly. It is surprising that with such a mild climate advantage is not more generally taken to cultivate in the open air many plants which in the eastern districts of Scotland we are obliged to grow in conservatories. Everyone who has travelled in Argyshire, particularly round the more sheltered parts of the coast districts, must have been surprised at the vigorous state of the *Fuchsias*, many of them of great size and age, and seeding abundantly. Many seedlings are now found in situations which make it evident that the berries must have been eaten, and the seeds passed by birds. So much is this the case, that in another generation the *Fuchsia* will probably be set down as an indigenous plant. In the western districts of Scotland, besides the *Fuchsia*, we frequently see the *Hydrangea*, *Arbutus*, *Escallonia*, particularly *E. macrantha*, with many other half-hardy plants, growing strong and flowering well. Among suffruticose plants, *Melanthus major*, *Euphorbia elliptica*, and *Erythrina laurifolia*, used to grow freely in the Edinburgh garden, and in several of the leading gardens of East Lothian. It is now a rare occurrence to see them, except in very sheltered situations near the sea; the vigour of former times, however, seems totally gone from them.

Our exotic walls, previous to 1837-38, used to be profusely covered with the flowers of *Magnolia conspicua* and *grandiflora*, *Passiflora cœrulea*, *Indigofera australis*, and *Bignonia radicans*. Although these plants still live, they do not run off into the flowering condition which we were formerly accustomed to see. The *Passiflora cœrulea* may occasionally produce a shoot sufficiently strong to bear a few flowers, but its beautiful golden fruit is not now to be met with. While on the subject of *Passiflora cœrulea*, I may state that during my frequent visits to Dublin, particularly about the year 1832, it was a rich treat to see the *Passiflora cœrulea* growing on many of the houses facing the south, in the southern suburbs of that city. The plants were trained on the houses with branches 30 or 40 feet in length, and covered in autumn with golden fruit—a sight which I have not seen even in Dublin for many years. About forty years ago the Strawberry tree, *Arbutus Unedo*, used to be one of the greatest ornaments of our shrubberies, particularly during the winter months, being then literally covered with clusters of beautiful red berries. During the year 1838 no fewer than 300 plants, exclusive of hedges, were killed in the botanic and experimental gardens, many of them averaging from 8 to 10 feet in the circumference of the branches. The largest specimen destroyed was 60 feet in circumference, and 18 feet high. At the same time a large *Arbutus Andrachne* was likewise killed; this plant was also 18 feet high, and the circumference of its branches 70 feet. The two latter shrubs were removed from the botanic garden at Leith Walk during the year 1822, when of large size, and planted in a border in front of a south wall. At the time of their death they could not have been less than 80 years of age, showing that they had enjoyed a climate suitable for their growth during a long series of years. About the time alluded to, the *Kalmia latifolia* also used to flower profusely in the open air, the plants being from 4 to 8 feet in circumference. For the last thirty years it has been a rare occurrence to see the *Kalmia* in bloom, and if seen, only a truss here and there, and that after a warm summer. To see the *Kalmia* in perfection now we must import them from the south, with flower-buds formed on them. At the present time the *Kalmia latifolia* is one of our handsomest evergreen shrubs, whether growing in black peat soil or leaf-mould and sand, and free from the roots of deciduous trees, often forming dense hemispherical plants, 4 feet in height, and from 20 to 30 feet in circumference. Few shrubby plants used to grow better and flower more freely than the *Erica arborea* and the

E. australis. They formed large bushes both on walls and standards. Although the former species now thrives and occasionally flowers, it is frequently cut down by frost, whilst the *Erica australis* has almost disappeared.

Proposed Substitute for the Larch.

The Larch also calls for a few remarks. I am inclined to think that a deterioration of climate must have taken place since the Larch was first introduced into this country; for how else does it happen that, from the enormous quantity of seeds annually imported, few of the progeny seem to have the vigour of the original tree introduced to Dunkeld and Monzie about 135 years ago? I do not wonder at debility existing in some of our Larch forests planted with seedlings raised from home-saved seed, as they are not unfrequently taken from trees covered with cones, and often diseased, which, indeed, causes many of them to assume a free-coning condition at an early period of their growth. But, when we see trees raised from foreign seeds becoming diseased before assuming a proper tree-growth, I am inclined to think that our Scotch climate is not what it was when the original Larches were first introduced into this country. A substitute for the Larch has long been talked of, but nothing definite has yet been adopted. I may here remark that I should like to see the *Wellingtonia* planted as a nurse-tree, as has long been done with the Larch. Independently of seeds, which can be got and often imported in very large quantities, no tree of recent introduction can be propagated faster, as it grows very readily by cuttings, which soon make proper and handsome specimens. A group of *Wellingtonias*, twenty-six in number, now in the botanic garden, were struck from cuttings about fifteen or sixteen years ago; they are all handsome and vigorous, averaging from 9 to 14 feet in height. From what I know of these trees I feel satisfied that if planted and brought up amongst other trees they will do better than if planted singly on Grass lawns, as we are accustomed to see them. It is said that the wood is soft on account of its free-growing nature; this may be the case in its native country, but in a climate like this it grows more slowly, and its wood, in consequence, may be fitted for many useful purposes.

It may be supposed by some that the Yew tree is not so hardy now as it once was, from the circumstance of few being seen coming on to take the place of the old trees now existing in various parts of the country. This, however, is not the case, as far as hardiness is concerned, but from the want of stem-pruning at an early period, so as to induce a tree growth. Many planted during the last thirty or forty years in gardens and shrubberies have been allowed to go on as bushes, instead of being stem-pruned at an early stage, so as to encourage an upward growth. It is on this account that we see some of our finest and perhaps oldest Yew trees in churchyards where, at an early period of their growth, they had from necessity been stem-pruned, to prevent their low branches spreading over much valuable ground. If the same pruning had been adopted in gardens and shrubberies as has been done in the churchyards, we should have many more of these beautiful trees scattered over the country than we now see. I feel convinced that the stem-pruning as recommended for the Yew, which would never assume a tree form without it, will be found equally beneficial for many other evergreen shrubs, such as the Cedar of Lebanon; many of those planted during the last forty or fifty years are often seen as large rounded evergreens, instead of assuming a tree habit, as would have been the case if stem-pruning had been early done. The same remarks hold good with many plants of the beautiful Atlantic Cedar as well as with *Deodars* and *Cupressus Lawsoniana*. Many of the unpruned specimens of this latter shrub will in time become like large unseemly specimens of *Arbor-vitæ*, laid open with every fall of snow, and spreading in all directions, which can never be the case with stem-pruned specimens. I feel certain that the stem-pruning of the shrubs just named, besides being beneficial to the tree by encouraging a tree growth, has also a tendency to render them more hardy, from the fact of the bark on the pruned stems being freely exposed and hardened, instead of being rendered tender by being closely surrounded with branches while in their shrub-growing condition. Numerous examples of pruned and unpruned specimens of the above species are to be seen in the botanic garden; the upward growth of the pruned stem over the unpruned is well marked, and I feel satisfied that during a severe winter the stem-pruned specimens will stand better than the unpruned ones of the same kinds.

At the periods to which I have alluded, we had not the advantage of horticultural periodicals to give us an account of the state and progress of vegetation of bygone periods for comparison with the state of the present time; I have, therefore, to detail what I have myself seen. These, with innumerable other examples, might be quoted to prove that a change must have taken place in our climate during the last fifty years. It must be evident to all that we have not the

amount of summer-heat that we were wont to experience in former times, nor yet the regular seasons in winters when frost at Christmas was as certain to be looked for and to come as Christmas itself, and which often lasted for weeks. Of late years, with but few exceptions, we have often as mild weather at Christmas as at any time during the year. The causes of these changes in our climate I am unable to explain, but changes have taken place, as evidenced by the almost total disappearance in the open air of the trees and shrubs alluded to, notwithstanding all the care and trouble taken to introduce them again into open-air cultivation.

In opposition to some of the remarks above given, I may state a circumstance which has recently come under my observation with reference to the *Tamarix gallica* which abounds in the villa gardens all round the south shores of England, its lively green colour being the admiration of all tourists, but it is rarely seen in the gardens or nurseries of Scotland. In a garden facing the sea at the East Bay, North Berwick, and having a northern aspect, the Tamarisk is growing admirably; the plants are each about 6 feet high, and present a contrast to the Fuchsias, Buckthorns, and other plants in the neighbouring gardens. Notwithstanding its beauty, it is strange to say that this plant is still confined to one villa. Judging from its weakly appearance in gardens away from the sea, I was of opinion that our maritime climate was quite unsuited for its growth.

Contrast between the Climate of England and Scotland.

It is undeniable that the climate of England is very superior to that of Scotland. Such trees as the *Catalpa syriaca*, *Paulownia imperialis*, *Gleditsia triacanthos*, and *Taxodium distichum*, cannot be grown in Scotland to the same state of perfection as in England. This, I believe, arises wholly from the deficiency of summer heat in Scotland, for in no instance are standard trees of these plants totally killed by any increased severity of winter cold in our northern climate, but as the new wood is not sufficiently ripened during summer and autumn, a considerable portion of it is regularly killed during the ensuing winter. It is also well known that the cold of winter, instead of being greater in Scotland, is in many parts not so severe as it is generally in England. Hence it happens that many plants, whose constitution renders them in a great measure independent of summer heat, can be grown in many districts of Scotland quite as well as in England, such as the *Yucca gloriosa*, *Y. recurva*, and *Y. filamentosa*, *Cordyline australis*, *Tritoma Burchellii*, and *T. Uvaria*, *Phormium tenax*, *Callistemon salicifolium*, &c. Neither is any difference observable in the growth and flowering of *Piptanthus nepalensis*, *Wistaria sinensis*, *Weigela rosea*, *Jasminum nudiflorum*, *Cydonia japonica*, *Andromeda floribunda*, *Leycesteria formosa*, and *Garrya elliptica*, when compared with plants of the same species to be met with in English gardens. All arboricultural observers who have travelled through England must have noticed the frequent difference in height of many of the English forest trees, particularly those standing alone on a level surface, as compared with those in similar positions in Scotland. Many of our Scotch trees seem to be somewhat dwarfed, rounded, and more twiggy at their points, as if a heavier atmospheric pressure had rested on them than on the southern trees of the same species. This is particularly noticeable in the Elm, Ash, Lime, Plane, and Sycamore. In Scotland, with the exception of the Silver Fir, few other trees are seen to mount so high, except in deep rich dells, where trees are generally tall, by being drawn in these peculiar localities. In some cases the flowering of certain hardy deciduous trees does not necessarily follow upon a fine summer. The Tulip tree (*Liriodendron tulipiferum*) and *Magnolia tripetala* are exotic trees which stand our climate well, and the wood, both young and old, has never, to my knowledge, been injured, even during our hardest winters. The flowering of these trees, however, is very irregular; in some years but few flowers are produced, while in others they are in abundance. The Walnut is another exotic tree which grows admirably in Scotland; in some years it produces fruit very scantily, in others in great profusion. The flowering and fruiting of these trees do not always occur after a fine summer. During the years 1870 and 1871 Walnuts were plentiful in Scotland on standard trees, but few or none were seen at Edinburgh during 1872. The Tulip tree and *Magnolia tripetala* flowered freely during 1872, but no flowers were seen on them during 1871; last year (1873) no flowers were seen on the Tulip tree, and the *Magnolia* only produced a few; showing that in some cases it takes more than one year to ripen wood sufficiently to bear flowers and fruit. It is very generally observed that the fruit of our ordinary forest trees ripen best during a good season, but in all cases when it has been preceded by a warm summer.

Fruit Trees.

During the years 1828, 1831, and 1834, I saw the Black Esperione Grape produce clusters of fruit on a south wall at Edinburgh, quite as ripe and as well coloured as during an ordinary season in England. During the same years the Black Mulberry was ripened to perfection.

Although the Mulberry not unfrequently produces fruit, I have never seen them in the same state of maturity at Edinburgh as they were during the years 1828, 1831, 1834, and 1868. Figs used to be frequently grown on open walls in many districts of Scotland, but how rare is it now to see fruit produced in a thoroughly ripe condition, without the aid of fire-heat. Figs, like the Vine and Mulberry, do not always ripen during an ordinary warm season, unless it is succeeded by another warm summer, when the wood becomes thoroughly matured. I need scarcely state that fruits which require hot-house culture to bring them to perfection, such as Pine-apples, the finer kinds of Grapes, also Peaches, Apricots, Nectarines, and Figs, notwithstanding an unfavourable season, and the frequent want of sun-heat, can be grown under artificial circumstances, to as great perfection in Scotland, both as to size and flavour, as can be done in almost any part of England. The foregoing observations on the effects produced by climate lead me to notice an article which I read in the *Journal of Horticulture* for December, 1871. It treats on the subject of Roses, and advises that observers in the different counties of England should select, out of a list of thirty-six kinds, the names of the twelve Roses which succeed best in their particular district. This is a step in the right direction, as far as the English climate is concerned, but we want a similar investigation for the climate of Scotland, not only for Roses, but for all open-air fruits, flowers, and vegetables. Of late years the rage for novelties both in the flower, fruit, and vegetable departments, has been greatly on the increase, and nurserymen have much to do in catering to supply the demand. It is well known that many novelties are produced in England, and considered deserving of cultivation, and often highly lauded in advertisements. Such novelties, although well adapted for the English climate, are not always suitable for the climate of Scotland, although many of them in time become distributed over the length and breadth of the country, either by seeds, plants, grafts, cuttings, layers, or runners, and after many years of careful trial, finally fail. If, as recommended for Roses in England, central committees could be formed to collect information throughout the various counties in Scotland relative to the best hardy varieties of Apples, Pears, Plums, Gooseberries, Strawberries, &c., and to ascertain which succeed best in each of our Scotch counties, it might lead to the securing, in each particular district, of an annual supply of fruit, fit for the table, instead of having a garden full of undoubtedly fine sorts, but which our Scotch climate is not sufficiently hot to mature. The wood of our finest Apples, like the Apples themselves, cannot be thoroughly ripened without heat. They become stunted in growth, and on the return of a fine summer it will be found that the wood has been so much injured that it is often impossible to get them into a good fruiting state again. How often do we see brakes of Gooseberry bushes, of the large fruiting Lancashire sorts, which rarely ripen to perfection in our most favoured Scotch counties, taking the place which ought to be filled by those varieties which have been thoroughly tested during a long series of years, and which are known to succeed well in a medium climate. The Strawberry is another fruit which has received much attention, and been considerably improved during late years. The improvement, however, has mostly been for the south. Many of the kinds recently introduced into our northern gardens, although growing freely, produce, except during a warm summer, but little fruit, in comparison with the old established sorts formerly cultivated; and I am sorry to find many of them rapidly disappearing to make room for so-called novelties, which frequently turn out failures owing to our fickle climate. Many of the old free-fruited sorts, although producing comparatively smaller berries, are still to be had; it would in many cases be advisable to raise seedlings from them, in order to secure varieties that will suit some of our colder northern districts. Seedlings raised from the large southern varieties will not always produce so hardy a progeny as seedlings taken from sorts long in cultivation, and proved to stand well in this country. How often do we see in the amateur villa gardens throughout Scotland the finest varieties of named Apple and Pear trees with high sounding characters selected from catalogues, or sent by first-class English nurserymen as being very superior kinds. I have known numerous examples of such first-class fruit trees being rooted out or cut down and re-grafted as being bad, and this after many years of abortive trial although the kinds in reality were good. The want of fruit, however, was generally owing to deficiency of climate. It has been too much the practice of recent years for new gardens to be supplied direct from southern nurseries, and it is quite natural to suppose that if left to the nurserymen themselves they will only supply superior kinds. It would be doing an act of justice if all our local or county nurserymen were to make themselves thoroughly masters of all the fruits which succeed best in their own district, and propagate accordingly; besides, such local nurserymen would do well to have a portion of ground set apart for maturing the kinds known

to succeed best in their respective counties. Buyers would then see and judge for themselves, and thus save much disappointment to amateurs and gardeners. Of what use would standards of the New York Pippin, Spitzenburg, or Blenheim Pippin be in many of our Scotch counties? I have seen trees of the New York and Blenheim Pippins on Scotch walls, with fruit miserably small, much deformed, and quite unfit for use. They are sorts for fine climates, requiring more sun than we can possibly expect, to ripen the wood, still more the fruit. The same remarks hold good with innumerable varieties which are now abundant throughout the middle districts of Scotland. After these observations I am inclined to recommend growers in each district to attempt the raising of seedlings, both Apple and Pear, from pips taken from kinds which are known to succeed best in their particular locality; by this means we may in time see many of our northern gardens stocked with a variety of Apples and Pears having well ripened wood and fruit, instead of innumerable trees stunted from the unpropitious climate, and eventually thrown out. At one time experimental gardens existed in London and Edinburgh, for the purpose of testing all the newly introduced varieties of open-air fruits, and for selecting the kinds to be recommended for growing in each respective country. To suppose that fruit proved suitable for London should be good in many districts of Yorkshire, or that those proved at Edinburgh would be adapted for many of our Highland districts, would be ridiculous. With the aid of walls and espalier rails the case is different, as, by their aid, some of the less tender kinds can be ripened successfully. Considering the average of our Scotch climate, I do not think it advisable, even on walls, to risk any very tender varieties; the fruit of such kinds is often small and flavourless for want of sun-heat. It is well known that some of the finer stone-fruit on unflued walls cannot be generally ripened to the same state of perfection as in former times, particularly Peaches and Nectarines. Flowers are generally produced in abundance, but little fruit ever comes to maturity. This also is attributable to the want of summer-heat to ripen the wood sufficiently to produce strong and healthy blossoms. Being weak, the blossoms, although produced in abundance, mostly fall off, even though protected from spring frosts by any substance except glass or heated walls.

Vegetables.

Besides fruits, there are several vegetables which have been introduced into English gardens which are considered too tender for our ordinary Scotch climate, unless in very favourable situations. Of Peas, many superior varieties have recently been raised and greatly extolled, but not more so than they are justly entitled to, being in many cases great improvements on kinds formerly cultivated. But, like the Gooseberries and Strawberries, we are better off with our well-known old and proved hardy kinds than with the highly-lauded new sorts. During a fine summer, the produce of the new kinds may turn out good, but during a season like 1872, a large proportion of Pea-straw was produced by some of these new kinds, with pods few in comparison with the extent of ground occupied to grow them. The Asparagus is another vegetable which in olden times used to be extensively grown throughout Scotland, but which of late years has become more and more scarce, evidently from the want of sufficient summer-heat to ripen the stems. In many of our newly-made gardens, Asparagus beds are dispensed with altogether, owing to the extent of ground occupied, and the irregular and often scanty crop produced. During former years, the Edinburgh market was freely supplied with this vegetable, reared by the market-gardeners in the district; now, it is mainly to be procured in the vegetable and fruit shops, the supplies being chiefly obtained from London. Many years ago, a variety was introduced into our northern gardens under the name of Giant Asparagus, which for several years was extensively used for planting. It soon turned out that the general temperature of our climate was insufficient for it, and it gradually disappeared, as well as much of the ordinary kind which had been so long grown. Of late years, many methods have been tried to induce a general crop of this favourite vegetable, such as the tying up of the summer-made shoots, instead of allowing them to blow about and break, which, no doubt, proves very detrimental to the shoot of the following year—likewise giving the beds a coating of sea-ware; but notwithstanding the precautions used for the stems, and the manure supplied, it is evident that our Scotch crop of this esculent does not increase. The Tomato is another esculent which in former years used to ripen and colour well, particularly against a south wall. Of late years it has rarely been seen with ripe fruit unless protected by glass. It is doubtful whether the Potato crop possesses the vigour it was wont to have. Occasionally, however, it is good. The fruits of the Potato, or Potato Apples, as they are called, do not now show themselves in that abundance in which they used to be seen almost regularly. Now, except after a very fine summer, they are of rare occurrence. Between the years 1820 and

1830, Mushrooms used to be found in the utmost abundance in many districts of Scotland, but few individuals at that time took an interest in them, from the feeling that they might not be the true sort. During the summers from 1823 to 1826, I was residing in the neighbourhood of Dollar, Clackmannanshire. All along the southern sloping portions of the Ochill range of hills, Mushrooms used to abound. I have myself picked on a limited space from two to three gallons in one morning. From information recently received from that district, I learn that this favourite esculent is now rarely to be met with on these slopes. The same remarks apply to several other districts of Scotland where I had been in the habit of seeing them. During moist warm summers they are occasionally got, but certainly not in the quantities in which they used to be found, and this is due to the fact that evidently the ground rarely gets sufficiently warm and moist for the growth of the spawn. In many districts of England, on the contrary, Mushrooms are produced in abundance, and almost every year, and although large quantities are annually gathered for the market and for private use, no diminution in their quantity is noticed, if the weather is at all favourable for them.

Acclimatisation.

Leaving the effects of climate on certain shrubs, fruits, and vegetables, I shall now offer a few remarks on what is termed the acclimatisation of plants; this is a subject which has long occupied public attention. I happen to be one of those sceptical individuals who do not believe in it, and still maintain the opinion that a plant is as hardy when first introduced into this country as it is after being half a century in cultivation. This, in a great measure, may be accounted for by our limited knowledge of the precise altitudes from which many plants were originally procured. It is well known that many of the plants of Upper India, Australia, and New Zealand will stand with impunity through two or three mild winters, and be killed outright during the third or fourth; but, to suppose that such plants, after standing out for several winters, are sufficiently hardened always to stand unprotected is quite a mistake. One of the plants which is often quoted as being thoroughly acclimatised in this part of the country, but chiefly, I may say, in the Edinburgh Botanic Garden, is the *Aponogeton distachyon*, which now grows vigorously in the pond. This plant is a native of the Cape of Good Hope, and was originally grown as a stove plant in the Edinburgh garden. It was afterwards cultivated in a large water-tank in the greenhouse, where it grew equally well. As the plant continued to increase rapidly, a quantity was placed by my late father, about forty years ago, in shallow pans and boxes, and sunk to various depths from 2½ to 4 feet, in different parts of the pond. This plant now covers several large spaces, the largest being about 24 square yards, and growing entirely in the muddy bottom. It flowers abundantly every year, and even through a mild winter, but during a severe one it is often killed down to its truncated fleshy roots. From its apparent hardiness, and profuse flowering, it is eagerly sought after by cultivators, but comparatively few ever succeed in growing it. A circumstance, however, attending the growth of this plant at Edinburgh which ought to be more generally known, and which I am in the habit of impressing on those individuals anxious to cultivate it, is this:—The situation of the pond was originally a marsh; it was excavated to the depth of from 2 to 5 feet. The bottom was composed of peaty clay, and is full of springs. When the pond was made, the bottom was causewayed with stones fully half an inch apart, to allow the spring water to rise freely between them. The bottom has now a thick coating of mud produced from the leaves of neighbouring trees, which are blown into it every autumn. In consequence of the springs bubbling up in all directions through the mud in which the roots are growing, ice is rarely seen on many portions of it. It is to these constant springs that I attribute the success of the culture of the *Aponogeton*. If this plant had been placed in the pond when it originally came from the Cape of Good Hope, it would have succeeded quite as well as it did with the stove and greenhouse culture it received before reaching the pond. Roots of *Aponogeton* have been sent to many ponds and lakes throughout the country. In Scotland very few individuals have ever succeeded, unless in those ponds treated with the condensed water from steam mills, evidently from the want of constant springs. Another example, and one which has been recorded as the result of acclimatisation, is the case of an old plant of a yellow-flowering evergreen Jessamine (*Jasminum revolutum*), a native of Madeira. The plant in question was for many years cultivated on the open wall. It was originally grown in a border, in a conservatory at the old botanic garden at Leith Walk. On relinquishing the old grounds, to give this Jessamine tree a chance for its life, it was brought over to the new garden during the year 1822, and placed against the open south-exposed wall, where it continued to thrive and flower in abundance, until injured by the severity of the frost which occurred during the winter of 1837-38. It partially recovered and

produced some new wood from the lower plant of the plant; but, although it grew freely for a time it never again assumed its original vigour, and was finally killed by the severity of the frost which prevailed during the spring of 1841. This, with numerous other examples, may be quoted to show that certain plants, although long grown in a conservatory and planted out while in full vigour, will thrive during a series of good seasons, but will succumb after an adverse summer followed by a severe winter.

Hybridisation.

The subject of acclimatisation leads me to another and very important matter connected with our open-air vegetation. After the introduction of the scarlet *Rhododendron arboreum* from India, which took place about fifty years ago, some of the original specimens, after being matured in the conservatory, were planted in the open air in various parts of the country. With a slight protection some of these plants survived over several winters, but finally died out. It was then generally remarked that there was an end to our ever seeing scarlet *Rhododendron* cultivated in the open air; but what could not be accomplished by acclimatisation was within eight or ten years successfully arrived at by means of hybridisation. We have not now the *Rhododendron arboreum* itself in the open air, but we have its colours infused into our ordinary hardy varieties, particularly those originally introduced from Gibraltar, Switzerland, North America, and the Caucasus, which at the time alluded to were abundant in our gardens. Those plants of *Rhododendron arboreum* cultivated in our conservatories soon flowered, and many individuals set to work to produce hybrids, both by placing the pollen of the hardy kinds on the scarlet *R. arboreum*, and likewise by fertilising the hardy varieties with the pollen of the scarlet kinds. The hybrids of the first-named cross, taken from the *R. arboreum*, were by no means quite hardy, and the colours far from being improved; while the latter crosses, using the scarlet *Rhododendron* as the male, proved eminently successful, and three distinct breeds were soon in cultivation. One between the *R. catawbiense*, a North American species, fertilised by *R. arboreum*, produced the varieties known, as \times *R. alta-clerense* and \times *R. Russellianum*, with a host of others which are nearly allied, and known under the name of \times *R. catawbiense arboreum*. The Gibraltar species, *R. ponticum*, fertilised with the *R. arboreum*, produced the \times *R. Cunninghamii*, also many other varieties very distinct both in habit, colour of flowers, and shape of leaf, when compared with the *catawbiense* breed. The plants produced from the two last named crosses have on several occasions been cut down by frost, but they always spring up again, which gives them more a bush form than a tree growth. Some of them, however, in sheltered situations among trees, do grow to a large size, and are frequently seen assuming a tree-like habit. Those plants raised between the Caucasian species, *R. caucasicum*, fertilised with *R. arboreum*, are exceedingly hardy and free-flowering. The ordinary *R. caucasicum* flowers abundantly in the open garden during the months of January and February, and the hybrids, which are now endless, are generally known under the name of \times *R. Nobleanum*, and are often seen in flower in the open border during the same early months. So truly are the varieties produced between the kinds just alluded to that we have only now to give orders to raise a batch of \times *R. Nobleanum*, \times *R. Cunninghamii*, or \times *R. alta-clerense*, as the case may be. Many of the hybrids are now made seed-bearing plants, and fertilised both by hybrids and true species; so much is this the case, that the varieties of *Rhododendrons* are now endless. Bees have also been instrumental in giving us many excellent varieties. Of recent years numerous species of *Rhododendron* have been introduced both from Sikkim and Bhotan; although many are comparatively tender, others grow freely in the open air; they are, however, subject to have their young growths destroyed by spring frosts, which makes them branch freely, and assume rather a bushy appearance. The wood in consequence rarely ripens sufficiently to produce flower-buds, and hence they require conservatory treatment, excepting, however, the *R. ciliatum*, *R. glaucum*, and *R. anthopogon*, which flower abundantly in the open air. These are Alpine forms resembling in some respects the *R. ferrugineum* and *R. hirsutum* of Switzerland. If a little trouble were taken, I do not see any difficulty in procuring some interesting hybrids, by crossing some of the hardy British or continental Heaths with some of the Cape species, as has already been done with the *Rhododendrons*. Size and colour might thus be given to an interesting race of plants sufficiently hardy to stand the climate of Britain. No doubt the operation will be a little tedious, but any cross produced will amply repay the trouble taken. A hybrid has been raised, or rather, I should say, it has been effected, between the *Menziesia empetriformis* and *Rhodothamnus Chamæcistus*. The cross is a plant well-known in cultivation under the name of *Bryanthus erectus*—a name which, by the way, it has no title to claim, that appellation being previously occupied by another Ericaceous plant. The production of this hybrid shows that, with a little trouble, difficulties may

be overcome by crossing some of the *Menziesias* with Heaths, *Rhodoras*, or dwarf *Rhododendrons*. The hybrid in question was first raised by Mr. James Cunningham, of the Comely Bank Nursery, and the identical hybrid was afterwards produced by Mr. Anderson-Henry, of Hay Lodge, from the same parents.

Evergreens.

Notwithstanding my remarks on the climate of Scotland, no one can deny that it ranks amongst the best in the world for evergreen shrubs, being neither too hot nor too cold for the generality of them. They are all to be met with in Scotland in as great a state of perfection as anywhere in England or Ireland; and, strange as it may appear, it is nevertheless true that certain exotic shrubs will thrive in Scotland, while the deciduous trees from the same countries are more or less injured from the want of climate. Great Britain (independently of Conifers) can perhaps boast of as many indigenous evergreen plants as almost any country, which naturally proves that it possesses a climate very suitable for them; and I think I am right in saying that the climate of Great Britain enables us to cultivate infinitely more species and varieties of hardy evergreen shrubs than any other civilised country in the world can at present boast of; and, although I have stated in this paper that our Scotch climate has been deteriorating with regard to certain species and varieties of evergreen shrubs, new species and varieties imported, or produced by accident or tentative measures, are increasing rapidly in this country. Evergreens, indeed, are not cultivated to the extent they ought to be. No doubt they are a little more expensive than deciduous shrubs. This extra expense is, however, well repaid by the clothed appearance which they give to our gardens and policy grounds, both for summer and winter effect. So much is this the case, that foreigners are always particularly struck with the quantity and size of the evergreens cultivated in this northern portion of the British dominions, such shrubs being particularly missed in France and Germany, and even America, which furnishes us with some good evergreen shrubs, such as *Kalmia latifolia*, *Rhododendron maximum*, and *R. catawbiense*; but they are generally found growing in a natural state in well-sheltered woods, where the severe winter frosts cannot reach them. The same remarks hold good with evergreens from European countries, where the summer climate is infinitely superior to that experienced in Great Britain.

THE ROYAL HORTICULTURAL SOCIETY; AS IT IS, AND AS IT MIGHT BE.*

In the form of a shilling pamphlet Mr. Wilson has issued the above reprint of his able letters on this subject, which have already appeared in *THE GARDEN*, and other horticultural papers, in addition to several replies from various quarters. We recommend this brochure to the attention of those who desire to possess the entire correspondence in a collected form. Mr. Wilson concludes with the following *resumé* of the questions discussed:—

I hope the perusal of these letters may lead others to the conclusion to which their facts have brought me:—1. That the society in its present form cannot last.—2. That the causes which have led to so much contention can only strengthen.—3. That it is no longer any question of who are on the council.—4. That the existing circumstances would baffle any council.—5. That the Society consists of two sections with different interests. The horticultural section, which requires admission to only a small portion of the South Kensington Garden for its meetings and shows; and the Kensingtonian section, which requires a large recreation ground.—6. That it is desirable that each section should have arrangements made with the commissioners for their respective requirements.—7. That, freed from the load of debt, of liabilities, and of charges, the society could carry on horticulture successfully with the subscriptions of 5,000 fellows at a guinea each.—8. That the consideration of a transferable ticket, admitting to all the society's shows in town and country, admissions to, and cuttings from, Chiswick Garden, and a vote by proxy, would be sufficient to induce 5,000 fellows to join the renovated society.—9. That a large number of fellows would join, not intending to visit many of the shows, but with the view of supporting a real national representative society for advancing horticulture.—10. That such a society would vastly spread the taste for, and knowledge of, horticulture throughout the country, and itself become stronger and stronger.

MR. THOMAS SUTTON, the photographer, states that, if calico is dipped for an instant in dilute sulphuric acid, it is rendered waterproof. The knowledge of this fact may be useful to gardeners.

* "The Royal Horticultural Society; As It Is, and As It Might Be." By G. F. Wilson, F.R.S. London: S. & T. Gilbert, 36, Moorgate Street. 1874.

THE END OF DE CANDOLLE'S GREAT DESCRIPTIVE WORK ON PLANTS.

At a recent meeting of the French Academy of Sciences, M. Alphonse De Candolle announced the publication of the seventeenth and last volume of that *magnum opus*, which had been commenced by his father in the early part of this century, and is entitled "Prodromus Systematis Naturalis Regni Vegetabilis." While the original design has not, as we shall see, been fully completed, the event, as it stands, is yet worthy of notice; and the following account of the work (for details of which we are mainly indebted to an interesting paper, by the younger De Candolle, in the current number of "Archives Des Sciences") may not be unacceptable to our readers. At the time when Augustin Pyramus De Candolle conceived the idea of his undertaking, the Linnæan classification ruled throughout Europe; and, in its brevity of description, it seemed to make botanists forget that there was aught in a plant but stamens and pistils. De Candolle early recognised the superiority of the Natural system, and became its apostle. His thesis on the medical properties of plants (1804) showed the uniformity of properties of each organ and each family; the "Flore Française" (1805) was the first flora of certain importance according to the natural method; and the "Théorie Elementaire" (1813) expounded the new principles with a conviction almost passionate. The completion of such work was evidently to apply the same ideas to the entire animal kingdom, to plants of all countries, and to all degrees of classification; particularly to sub-divisions of families and of genera, which had commonly been neglected. An entire revision of the vegetable kingdom did not then seem beyond the powers of one man. Some 25,000 to 30,000 species were known; and, by a singular illusion, it does not seem to have been considered how small was the surface of the globe already explored, or that each region had its distinct flora. Thus, however, an important work was begun, which has continued sixty years, and which, though coming short of its original aim, has yet produced an unexampled series of 214 monographs of families of Dicotyledons, comprising 5,134 genera, and 58,975 species; that is, twice as many species as were thought to exist when the work began, and eight times as many as are found in Linnæus's two volumes of species. The first articles for the "Systema" were prepared by M. De Candolle himself (the Elder), from an examination of French and English collections. He was at pains to cite the localities, the travellers, the collections, the descriptions, and the figures published in all the countries (a thing which had been little done before); adopting the principles of Tournefort for genera, of Linnæus for species, and of Jussieu for families, the innovations were to group the families in cohorts, the genera in tribes, the species in sections or paragraphs, according to the principles of the natural method. He disregarded no details of information furnished; he was wont to say, that if he were to choose a motto it would be, "Nihil botanicum a me alienum puto." The two volumes of the "Systema," published in 1818 and 1821, contain eleven families, and had taken seven or eight years of work. De Candolle (not foreseeing the enormous growth of collections, &c., in later years) estimated that it would require eighty or one hundred years to complete the review of the vegetable kingdom thus, considering the number of species then contained in herbaria. And it was not till 1832 or so that he began to contemplate the need of co-operation. The two first volumes of the "Prodromus" (1824 and 1825) were edited in the most concise form. The first third of the first volume contains an epitome of the eleven families of the "Systema," with addition of some genera and species; then follow fifty-three other families, including the specially important Leguminosæ. Volumes III. to VII. were a little fuller, and were, like the first two, edited by De Candolle almost entirely alone. The "Prodromus" now became the regulator of descriptive botany. The order adopted for families was followed by most publications. Travellers from abroad furnished their collections in a most disinterested way; and, on all hands, the author was supported and encouraged in his enterprise. His last and supreme effort was the revision of the family of the Compositæ. A serious illness suspended work for a year, and it seemed urgent to secure a number of *collaborateurs* among

the eminent botanists of the day. Promises were obtained from the following, among others:—MM. Bentham, Duval Decaisne, Grisebach, Choisy, Duby, Boissier, Moquin-Tandon and Meissner. De Candolle died on the 9th September, 1841, and it fell to the son, M. Alph. De Candolle (then thirty-five years of age) to direct the work which had been successfully begun. With the aid of, altogether, some thirty-three *collaborateurs* he has been able, in thirty-two years, to add ten volumes of monographs to the seven his father published. He takes special notice of assistance from MM. Bentham, Meissner and Müller, the keeper of his herbarium. Commenting on the slowness of the appearance of the "Prodromus," M. Alph. De Candolle makes reference to the manifold difficulties connected with such an undertaking; more especially, those incident to an extensive co-operation of the kind indicated. There is, too, the great development of science; and the author points out that, with the abridged form adopted in the first volumes of the "Prodromus," it was possible for his father to edit as many as ten articles of species in one day; now, on the other hand, a monographer, having so many more specimens and books to compare, and having to investigate the most minute characters relative to ovules, embryos, &c., cannot well study and describe more than 300 to 400 species in a year, say, on an average, one species daily. The "Prodromus" has only been carried to the end of the greatest class of the vegetable kingdom, that of Dicotyledons; and it there meets Kunth's "Enumeratio Plantarum" which contains the families of the Monocotyledons with the exception of Orchideæ. The two works thus contain the *ensemble* of the Phanerogams; edited, indeed, very differently (the "Prodromus" being more detailed, and having more new species), but treated according to the natural method and the state of science about the middle of the nineteenth century. "If it were required," says M. De Candolle, "to commence a new series of monographic works on a scheme similar to that of the 'Prodromus,' it would not only be necessary to compare many more books and herbaria, but to examine the characters of evolution presented by living plants, and those of the anomalous composition of the bark, wood, &c., all which call for the use of the microscope. The first thing to do would be to read all the works or memoirs of anatomy, and all the treatises which deal with elementary organs, so as to note what has been observed in, say, twenty years, in such and such a species or genus of plants. Facts of this nature should distinguish the groups. Unhappily, anatomists give little in the way of *resumé*, and when they do give it, it is with forms of speech which little allow of comparison between one book and another. The character of species, genera, families, &c., in works of descriptive botany, are enunciated in a way which facilitates comparisons; but there is nothing of this in the treatment of organs. To know accurately how two authors, differing in opinion, consider a particular layer of cells to be placed or formed, it is sometimes necessary to study 100 pages, and in different languages. The introduction of microscopic details into the regular text of a description of forms, thus demands peculiar bibliographic labour. Classification itself requires to be extended and completed; the sub-divisions of species can no longer (as formerly) be neglected. The time is not far distant when all genera will be known, as all families already are; but the number of species will still increase sensibly to the end of the century, and even beyond it. The volumes of the Prodromus, while they have destroyed many bad species, have added regularly to science 25 per cent of new species. * * * A work similar to the 'Prodromus' if now undertaken, would give, for the first half of our volumes, an increase of species by 80 per cent. at least, and, taking the second half into account, the increase would perhaps, be 50 per cent. for Dicotyledons. This is the most likely, as the work would last a greater number of years, during which new species would be introduced. The 'Prodromus' contains 58,975 species of Dicotyledons, and if the Artocarpeæ had been edited in time, there would have been altogether about 60,000 species. Add a half more, and the revision to be made now would contain 90,000. If we waited twenty or thirty years there would be more than 100,000, and we should then, I suppose, be near knowing all the species of this class which exist. The Monocotyledons, according to Lindley's probable estimate, are in number about a fifth of the Dicotyledons."

There would thus be 18,000 to 20,000 species to add for this class, and the Phanerogams would thus comprise from 100,000 to 120,000 species, according as the revision was made now, or later, and with more extensive collections. Suppose 110,000 species. This number, at the annual rate specified for an active botanist, having complete resources in the way of books and herbaria, would require 366 years; say, thirty-six or thirty-seven years for ten botanists; eighteen or nineteen years for twenty; or fifteen or sixteen years for twenty-five. It is hardly possible to allow a greater sub-division, because the family of the Compositæ cannot be divided, and it would require fifteen or eighteen years' work for one man alone. Moreover, experience has taught me that, increasing the number of *collaborateurs*, we do not advance proportionately. The essential thing would be to have capable botanists, working regularly and devoting themselves entirely to making monographs, or, at least, leaving it only so far as was necessary to prevent their succumbing to the fatigue of their labour. Will these twenty or twenty-five monographers be found? It appears to me very doubtful. Assuredly, when all the volumes of the 'Prodromus' have become old, and are no longer more abreast with science than the first part now is, and the work of Kunth on Monocotyledons; when thousands of species will have been described in different ways, in a multitude of books and papers; when compilations, more or less good, have shown the little solidity of many of these species, and how desirable it is become to revise them according to nature in a comparative manner; there will then be a demand, on all sides, for a new work dealing with the whole. Some daring spirits will, perhaps, commence such a work, but if they have not found a means of co-ordinating a vast system of labour in Europe and America, they will assuredly fail. I doubt also if a single director will suffice, and that he will be found in the future. The original author of the 'Prodromus' was a true master of a school. By his character, his superiority, his activity, he attracted numerous friends and disciples. His undertaking, greater than he thought it, has been continued by his sons and grandsons. It proceeded, moreover, from a small, weak, neutral country, intermediate between the great countries which are so jealous of each other. This is an advantage for a work which must be essentially cosmopolitan, and in which recourse must be had to *savants* of various nationalities. It is necessary to perform the work with a completely impartial spirit; without touching susceptibilities foreign to science. It is thus we have had *collaborateurs* belonging to different nations. But at the present time, it is less than ever possible to suppose Germans and English submitting to the direction of a Frenchman, or French and English consenting to impulsion from a German. Further, if we conceive a botanist in one of the smaller countries, like Holland, Denmark, Belgium, Switzerland, forming a scheme like that of the 'Prodromus,' he would find it difficult to combine the direction with a considerable share in the editing. I may say, from my own experience, that the one occupation is adverse to the other. The impulsion must rather, it seems to me, be collective; and the way in which I suppose it will occur, perhaps twenty or thirty years hence, when the confusion of works on botany has become very great, will be somewhat as follows:—I imagine that proprietors or directors of six, eight, or ten of the principal botanical establishments, public or private, will conceive the idea of arranging to edit, each on his own account, monographs of certain large divisions of phanerogams, on a plan pretty uniform. Each of these *savants* will engage *collaborateurs*, choosing them himself. He will publish their work as and when he can do so. The Dicotyledons will, *e.g.*, be entrusted to five, six, or seven directors. One will take the Compositæ, another the Corollifloræ, a third the Thalamifloræ, and so on. The Monocotyledons will be entrusted to other directors. Once the work has begun, through the agreement of a small number of men, a laudable emulation will spring up between the different centres. National self-love, in place of injuring, will, in this case, further the cause of science. * * * With the system I have indicated, not only the authors, but also societies, general protectors of science, and Governments, would be roused by a sentiment of honour to promote the enterprise in each country." M. De Candolle finally urges the importance, meanwhile, of

publishing good monographs of families, tribes, and important genera; and he puts his library and herbarium, in Geneva, at the service of any monographers who may wish to make use of them.
A. B. M.

A CHEAP STOVE.

AN economical and efficient stove for a small greenhouse or conservatory can now be purchased for 8s. 6d. It is named "The Glow-worm," and consists of an iron pot on four short legs; an aperture being provided in front for the draught, with a moveable piece to regulate it. It has also a ring top and cover, both moveable. The grating is about 1 inch from the bottom, and the flue rises from the back at the top, and so saves an elbow joint; its entire height is 12 inches. It is used by nearly filling the pot with coal, in small pieces (no dust), leaving a little hollow in the centre for some paper and half-a-dozen pieces of firewood; a little more coal is placed on the wood, and then lighted. Place the ring and cover on at once to prevent the escape of smoke, and it will burn for seven or eight hours. But I find, by placing a piece of sheet iron or tin on the grating, covering about three-fourths of it, it will burn for twelve or fourteen hours without any attention whatever. I generally light it about 8 o'clock in the evening, and at 8 next morning I remove the cover, shake the fuel together, and add coal and coke; and at 8 the next evening I repeat the process, emptying the stove about every third day. The best way to do this is to tilt the stove in front and draw it out of the flue, carry it out of the greenhouse, and empty the contents into a sieve; the larger pieces can be returned to the stove again, and you have no dust in the house. I have added a top to my stove, of sheet iron, about 8 inches high, and if some coke is placed in this after the stove has burnt some eight hours, it may safely be left for sixteen or eighteen hours more without attention. If it burns too fast, reduce the supply of air by means of the regulator. My house is 12 feet by 6 feet 6 inches, rising 8 feet high, and, as the chimney stack is 30 feet from the stove, the iron flue-pipe is nearly horizontal, and warms the house equally throughout.
A SUBSCRIBER.

A SPADE-HOE.

THE accompanying is an illustration of a tool I use for hoeing up Potatoes, Cabbages, &c.; or, for any work where a furrow

is wanted. It is simply a boy's spade, 5 in. wide and 8½ in. long in the blade, cut sharp at the end, and having about two-thirds of the plate turned up at an angle of 45°. In using it, one foot follows the spade, the other being in the next row. The advantages are, that the sharp point goes easily into the ground, and much or little of the soil is thrown up as may be required. As it is a new tool, gardeners generally may not like it, but amateurs who want to save labour and time, should not be without it.
C. J. C

WORK FOR THE WEEK. PRIVATE GARDENS.

Flower Garden.—Snowdrops, Hellebores, and winter Aconites still continue to expand their blossoms; Crocuses, too, are beginning to bloom, and bulbous plants, in general, are making good leaves that still seem unscathed. Wallflowers are now blooming freely, and different kinds of Viola, Arabis, and Aubrietia are beginning to unfold their flowers, although the weather is at present anything but favourable for spring-blooming plants. Daisies and Hepaticas, also, promise a profusion of floral beauty, while walls are ornamented with the cheerful yellow blossoms of *Jasminum nudiflorum*, and *Chimonanthus fragrans* in many places is still in good condition. *Berberis Aquifolium*, and *B. Darwinii*, with its small leaves and deep golden flowers, likewise contribute nobly to the enrichment of our gardens now, and will continue to do so even more extensively during the next two months. All empty flower-beds should receive a good dressing of leaf-mould and decayed manure, and be deeply dug or trenched. Where hardy material can be spared for replenishing

flower-beds and borders, planting may be proceeded with. Pansies, Daisies, Arabis, Alyssums, and similar early-blooming plants, transplant as well now as later in the season; indeed, if carefully removed, they suffer little or no check in the operation. Ground for the reception of hardy herbaceous plants should be trenched and heavily manured, but the sub-soil, unless good, must not be incorporated with the surface soil. Where *Lythrum roseum* is used in ribbon-border making, it should now be lifted, cut up into good crowns, and replanted in a line about 15 or 18 inches apart. *Salvia fulgens* in light soils may be treated in the same way. Sweet Peas should now be sown where they are to bloom, and some should be put in beds from which to make up deficiencies in case of failure; sow a few in a box under glass. Sow, also, some Mignonette in rows or broadcast, where early-blooming plants of it are wanted to flower. Some *Saponaria calabrica* seeds should be sown on a wall border for transplanting. A few seeds of *Tropæolum canariense* may also now be sown in a similar position, and a few twigs of Broom stuck in front, so as to protect the young plants, when they come up, from cold winds and frost. When the weather is dry add some tufty loam and well-decomposed manure to beds where large plants, such as those of *Ricinus*, *Ferdinanda*, *Wiganda*, and other gross feeders, are to be grown, *i.e.*, if the beds are now empty. If the soil last year was found to be too moist, turn it out, and place a layer of stones, broken bricks, &c., in the bottoms of the beds. Mulch all newly-planted shrubs or trees, and affix strong, but neat, stakes to such as require support. Prune back, pretty hard, some Clematises for early-flowering; some of the hardier Rose plants may also be pruned for the same purpose. Tree-Pæonies, Myrtles, the Japanese Quince, and several other rather tender plants, should have a little protection from frost; for, although their roots and principal stems might escape unhurt, their young shoots might be considerably injured. Lay Box and other edgings, and prune and tie up climbing plants. Where new lawns are intended to be made, the ground should now be cleared of all superfluous trees and shrubs, and the soil should be trenched over, turning all rough material into the bottom of the trenches, and making the whole perfectly level, smooth, and firm by means of rolling and raking. The seed should be sown in the latter half of this month.

Bedding Plants.—Hot-beds should now be put up for the propagation of these where hot-water-heated structures are not available for that purpose. Such beds may either be raised above the ground or sunk, and in extensive places some of both kinds will be found serviceable. A little extra warmth may be communicated to ordinary frames by means of a lining of fermenting material applied to their sides; this additional heat will induce the plants to start into growth and to soon begin to yield material for cuttings. Where two, three, or more *Pelargoniums* were placed together in one pot in the lifting season, for convenience of storage, they may now be separated, potted singly, according to size, and kept without water for some days after the operation. Keep the house or frame rather close for some little time after potting. Lose no time in obtaining and striking as many cuttings of all plants as possible, for the stronger they are, and the earlier propagated, the hardier and the more vigorous will they be when turned out in the latter end of May. *Calceolaria* cuttings seldom root well in spring; nevertheless, the tops of autumn-saved plants may be economised for that purpose in the event of an otherwise deficient supply. If struck in a cold frame early this month, in the same manner as autumn cuttings are, they sometimes root very satisfactorily. *Verbenas*, *Heliotropes*, *Ageratums*, *Tropæolums*, *Petunias*, *Lobelias*, *Coleuses*, *Alternantheras*, *Iresines*, &c., when rooted, should be potted singly or transplanted into boxes, and still be kept in heat, as their tops can very soon be taken off for the same purpose, and also their side shoots, so that, with plenty of heat and convenience, a large supply may be obtained before the end of the next two months. Sub-tropical plants must also be increased as expeditiously as possible. Side shoots taken off for cuttings soon make good plants. Seeds of the various kinds commonly raised by that means should now be sown in a brisk hot-bed or warm pit. *Acacia lophantha*, *Wigandias*, *Cannas*, *Ferdinandas*, *Ricinus*, *Zeas*, and many others, can be readily raised from seeds. *Canna* roots saved from last year should now be divided and started in heat. *Dahlia* roots may also be started. If beds be dug out about 18 inches or 2 feet deep, and filled with leaves trodden firmly, so as to be covered by a frame, and some light rich soil be placed therein, they will form excellent positions in which to plant *Calceolarias*, *Verbenas*, or *Heliotropes*, so as to have grand plants before they have to be set out in beds.

The Early Peach-house.—The fruit will now be set in the earliest house, and syringings morning and evening will be required in favourable weather. Attention should likewise be paid to the thinning of the fruits where they are set thickly, but this rarely happens when forcing commences so early. The dis-budding of the shoots is a process best performed by taking off only a few of the

strongest at different times, so as not to give a check to the root. The temperature at night may be maintained at about 60°, with a rise to 70° by day, and by sunheat 6° or 8° higher. Green-fly will begin to make its appearance, and the infested shoots must be picked off; but fumigation with tobacco will have to be resorted to at the last. Some of the new patented fumigators are very efficient for the purpose, for by making a hole in each door of the house for introducing the nozzles from the outside, the house will be soon quite filled with smoke, and kept so for any length of time required.

MARKET GARDENS.

This mild winter has enabled market gardeners to push on their outdoor work with comfort. Digging and trenching are now in a remarkably forward state compared with this time last year, while the ground in some districts was completely flooded. Outdoor vegetables have been excellent this winter, and Seakale, Rhubarb, and Asparagus are furnished in large quantities from frames and forcing-pits; while from France come Asparagus, Lettuces, and other salad vegetables. The third crop of Radishes, being now sown, should be kept covered with litter until the young plants appear above ground. The earliest-sown plantation requires no more protection from birds; but the covering should be replaced in the event of frost. Remove into the alleys between the beds, every fine morning, the litter-covering belonging to the second plantation, so that the plants may gather strength, become green, and also that the surface-soil may get dried, as well as the litter covering it. Use a long-toothed wooden rake for removing the litter, and a steel-pronged pitchfork for replacing it. Keep a boy at each plantation to frighten the birds, which, if permitted, are very destructive to the Radishes after they appear above ground. Various bird-scares have been used, but none are so effectual as boys. Rhubarb is beginning to grow a little naturally; therefore, rake all litter lodging about the crowns into the alleys, which should be dug as soon as possible, if not already done, and the crowns in open plantations covered with fresh litter; but those under the shade of fruit-trees may remain until the last. A good forkful of strawy litter is sufficient for each crown, and is of great service in protecting the crowns from cold, and preserving the leaf-stalks from grit; besides, the Rhubarb produced under the litter is always crisper and milder than that grown without any protection. It is impossible to wheel or cart manure on to the plantations with impunity, therefore get some of your workmen to fill baskets with litter, and others to carry them on their heads to the place where the litter is required to cover the crowns. Before digging the ground lately occupied by Seakale, some women go over it and pick up every piece of root they can find, otherwise they will grow and cause annoyance. In digging the ground, too, every bit must be picked out and thrown on the surface, to be gathered off afterwards. Cut up the best pieces of the Seakale roots, that were cut off the forcing crowns, into fine length pieces, and lay them quite thickly on a well-packed raised bed, and place a layer of soil, an inch or two in depth, over them. Leave them there until March, then, after dressing them, dig them in amongst Cabbages or Cauliflowers, so that they may occupy the ground after these crops, and one of Lettuces have been obtained from it. All refuse roots throw into a heap, and burn them, or decompose them with lime. Uncover, throughout, every dry hour frames containing Lettuces and Cauliflowers. Thin the Lettuces, if thin, especially if Carrots are growing amongst them. Tilt up the hand-lights over Cauliflower in fine weather, which, if very mild, but replaced at night. Hoe the ground between Cabbages, and keep the loose and warm surface soil is very beneficial to them. Keep Onions free from weeds, and prepare a slight hot-bed for sowing sowing Leeks in, for early transplanting. For early Turnips prepare sowing beds by the following method: Cast out trenches, or beds, from 6 feet wide, and about a foot deep; fill these with fermenting manure and cover it over with a few inches of soil. Then sow the seeds and cover them thinly with mould, and over all place a mulching of litter a little deeper than what is generally done over Radish beds when the seedlings appear this mulching must be removed and replaced daily, as in the case of Radishes. Mushroom-beds are bearing this winter, and, in order to keep off heavy rains and retain the heat, place mats over them; a declining of the heat, however, can be greatly remedied by additional covering of litter. Continue to sow in succession, beds of Asparagus, Seakale, and Rhubarb. Frames are unnecessary for these, providing the alleys are well filled with manure, some of which should, also, be placed over the surface of the beds, which ought then to be covered with hoops and mats, strewn with straw or strawy litter. Collect and burn all refuse, such as old and useless trees and bushes, and prunings. These should be burnt in a heap in one place, and the ashes carefully collected and mixed with manure intended for beds of any choice vegetables.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE ORIGIN OF DOUBLE PELARGONIUMS.

By THOMAS LAXTON, Stamford.

THE friendly glove thrown down by Dr. Denny in last week's GARDEN anent the origin of my strain of double Pelargoniums, which he suggests I may have obtained from the Continent, impels me, in the midst of political strife, to accept the challenge, and to enter upon ground I had not just now intended, M. Sisley's and Dr. Denny's communications being so full of interest to raisers of new plants. In 1866, I commenced crossing the Triomphe de Gergoriat or Inquinans race of double Pelargoniums with the ordinary single Zonals, but, after a three years' trial, I found it impossible to get out of the vigorous and "fat" growth of that class of doubles, all my seedlings, with one exception, showing no material variation from or advance on their parents, the exception being the result of a cross of Triomphe de Gergoriat with single Zonal White Princess, which had foliage approaching that of the pollen parent, and small reddish flowers with whitish reverse of petals. This was the only seedling I succeeded in raising from many attempted crosses of any of the Madame Vaucher race with the Inquinans doubles, and it was infertile. I ought to state that I have only exceptionally used the single varieties as seed-bearers, on account of the greater security from self or foreign fertilisation which, under ordinary treatment, the opposite method affords, and I have never been able to obtain seed from any of these doubles by fertilising them with single Zonal Beauté de Suresnes; the converse I have not tried. In 1869 finding that so little was to be gained by crossing the Gergoriat or Champflour type, I discarded it for Madame Rose-Charmeux and Mr. W. Paul's Cottington, the two double Tom Thumbs, the origin of which I should much like to ascertain; doubtless, they are both sports from Tom Thumb, for I have found Rose-Charmeux to throw out a branch (probably a reversion) with single flowers only, and which I could not distinguish from Tom Thumb. I am afraid M. Jean Sisley's account does not touch on the origin of these, nor does he seem to have noticed in one of the English papers of the past two years, a quotation from a Scotch publication of about 1826, from which it would appear that a double Zonal was in existence, in a Belgian nursery, nearly fifty years ago, and, from the not over-flattering description of the plant, I take it to have been a similar variety to Marechal de Champflour. From Madame Rose-Charmeux I obtained Jewel by fertilising with Lord Derby and E. J. Lowe, by using the pollen of a seedling from Mrs. Pollock, and it is remarkable that the vigour of this variety exceeds that of either of its parents and that of the other seedlings produced by fertilisation with the non-variegated single Zonals. Most of the seedlings from Madame Rose-Charmeux, having double flowers, were infertile, and from Jewel I could only get a single seedling, which I have since lost. Rather more than half the produce of over 1,000 seedlings from Madame Rose-Charmeux, raised in four years, came double or semi-double, the foliage and habit taking a more or less intermediate form, and none having the characteristic zone of the male parent entirely absent in the foliage. I have never been able to get nearer a white-flowered double than a light pink, and this appeared to be an exceptional sport, no white or pink variety having been used in the cross. A corresponding circumstance has occurred in crossing the single dwarf scarlet Zonal Harry Hieover with another scarlet Zonal, one seedling from it having flowers nearly white, or parti-coloured, not unlike the Continental variety Cora, but I could never get anything like a white flower by crossing Madame Rose-Charmeux with the Madame Vaucher type, and I have always found the white in flowers much less than other colours; and, in both the cases alluded to, the parents had each scarlet flowers, the light colours being probably due to reversion. It will, therefore, deeply interest me to know the origin

of the parents of M. Jean Sisley's break in Aline Sisley, which has quite the Madame Vaucher habit and character, and no traces of Inquinans blood appearing in it. I have now several hundred seedlings from crosses of the double Tom Thumb race with the single Zonals and Nosegays, many showing remarkable variations in colour and improvement in form. I have others, also, crosses between these and a shrubby single-flowered dwarf Zonal, having Parsley-like foliage, and which may be, and has been, considered a hybrid between an old self-coloured show Geranium and a scarlet Zonal; but, as I have not followed out carefully the results of some crosses which I attempted in this direction a few years ago, I am unable to speak with certainty on the point; although the appearance, scent, and general want of fertility of the parent seedling indicate such an origin. In conclusion, I would ask hybridisers not to come to a hasty determination, from Dr. Denny's observations in crossing the Pelargonium, as to the prepotence of the male parent; for, although the doctor's experiments have been undoubtedly carefully conducted, and his observations on the results are equally reliable, I maintain that all such highly interbred plants as the Zonal Pelargonium, the Rose, florists' flowers generally, and even cultivated fruits, afford no safe field for such a deduction, because reversion, and the causes alluded to by Mr. Darwin, are too likely to affect the results. On the other hand, after nearly twenty years' experience in the cross-fertilisation and hybridising of plants, during which time I have conducted, and, in many instances, carefully recorded the results of some thousands of crosses and counter-crosses with genera less interbred, and, consequently less liable to reversion, and especially the Leguminosæ, which are not easily subject to the accidental influences of foreign pollen, I have not been able to obtain any evidence that the influence of one parent, in the vegetable kingdom, predominates over the other, although I have had frequent proofs that the general results of cross and counter-cross are indistinguishable. The particulars of these experiments I hope, if spared, at some future day to codify.

In allusion to the paragraph in the same page of THE GARDEN, headed "A blue Pelargonium," I must be allowed to repeat what I have before written, that I doubt the probability of a hybrid being raised between Geranium pratense and the Zonal Pelargonium. Eighteen years ago, I tried ineffectually to cross them in a variety of ways, using for the purpose Madame Vaucher and the principal whites of the period, both as the male and female flowers, and, although I have seen some of Mr. Lowe's seedlings, I must still give my verdict as "not proven."

The Nutmeg.—This spice, so much used in every family, is indigenous to the Moluccas, reaching its greatest perfection in Amboyna. This island belongs to the Dutch, who do not permit the cultivation of the Nutmeg in the other islands under their control. The Nutmeg-tree is 25 or 30 feet high when fully grown, with foliage of a rich dark green, and very plentiful. It reaches maturity, or full productiveness, at the fifteenth year from planting. From the blossom to the ripening of the fruit takes about seven months; but, as the tree is a perennial bearer, there are always blossoms, green fruit and ripe on the tree. The yield is most plentiful in the last four months of the year. The average yield per annum of a healthy tree is 5 lbs. of Nutmegs and 1½ lbs. of Mace. A plantation of one thousand trees requires the labours of seven coolies, fifty oxen, and two ploughs, for cultivation and harvesting. The fruit is gathered by means of a hook attached to a long pole. It is shaped like a Pear, about the size of a Peach, and has a delicate "bloom." The nut has three coverings; the outside one is a thick fleshy husk, having a strong flavour of Nutmeg. This husk, preserved in syrup when young, is a favourite sweetmeat in the East Indies. Under this husk is the bright red mace, which is carefully flattened by hand and dried on mats in the sun. It loses its rich scarlet, and becomes a dull orange colour, and requires to be kept perfectly dry to preserve its flavour. After the Mace is removed from the fruit, the nuts, in their brown shells, are placed on hurdles over a slow fire, which is kept constantly burning under them for two months. The nuts then rattle in the shells, which are cracked with a wooden mallet, the sound nuts selected and packed in wooden cases, and sprinkled over with dry sifted lime, and are then ready for market. The best Nutmegs are dense, emit oil when pricked with a pin, and can always be known by their heavy weight. Poor ones are light and easily detected.

NOTES OF THE WEEK.

— IN the Royal Botanic Gardens, Edinburgh, *Cordylina australis* has proved itself to be hardy enough to withstand the winter, when planted on rock-work, where its elevated position ensures perfect drainage, whereas in flower-borders in the same gardens our winters generally kill it.

— WE learn from the *Illustration Horticole* that a species of Gum-tree which "surpasses the *Eucalyptus globulus* in interest," is now being cultivated in Algeria. It is named *Eucalyptus colosseus*, and, in its native Australian home, is said to attain a height of 400 feet.

— THE office of Secretary-General to the Central Horticultural Society of France, recently vacant, in consequence of the death of M. Bouchard-Huzard, has been filled by the appointment of M. A. Lavallée, a distinguished amateur, well-known on the Continent from his writings on horticultural subjects.

— A SOCIETY of Acclimatisation has recently been established at Rio Janeiro, with the object of introducing into Brazil useful animals and plants from other countries. For this purpose an extensive garden, similar to the Jardin d'Acclimatation at Paris, is in process of formation, under the superintendence of M. Glazion, the director of the public gardens at Rio.

— IN the *Official Gazette* of the United States Patent Office, of date of November 11th, 1873, we find that a Mr. John Craig has patented what he terms an "Artificial Stem for Cut Flowers," which is nothing more than the old device of winding a bit of fine annealed wire around the base of the flower, a practice which has been resorted to for years by our best florists.

— A VERY handsome variety of the common Almond (*Amygdalus communis*), with variegated leaves, has been raised by M. Ausseur-Sertier, nurseryman, of Lieusaint (Seine-et-Marne). In most cases, variegation of the foliage is accompanied with a loss of vigour in the tree or plant in which it occurs, but this variety is said to preserve all the vigour of the type, while it displays a beautiful contrast of colours in its leaves, which are of a fine green, marked with snow-white streaks, and very much resemble the leaves of a variegated *Negundo*. Plants of it are offered for sale by the raiser.

— A NEW species of Pumpkin is announced from the *Jardin d'Acclimatation* at Paris, under the Spanish name of "Zapallito de tronco," or "Tree-Pumpkin." It differs from all its congeners in its mode of growth, as, instead of trailing, it forms erect tufts, with numerous fruits of a depressed spherical shape, and from 5 to 8 inches in diameter, depending from the stem. These are said to be of excellent quality and flavour. The chief merit of the plant, however, is that, from its mode of growth, it occupies very little space in cultivation, while a single plant of any other species, usually covers a large area. The seeds of the Tree-Pumpkin, here described, were obtained from Buenos Ayres.

— THE old gravel-pits and belts of Furze on the west side of Tooting Common are being cleared away, and the land is to be excavated and laid out as a public park and recreation-ground for the inhabitants of Tooting and Streatham. The work is undertaken by the Board of Works, who have purchased the manorial rights, and arranged with the commoners having pasture rights and other privileges. The other portion of the common, about which there has been expensive litigation between the lord of the manor and the commoners, is to remain intact. It is beautifully timbered, and possesses a park-like aspect, and is to be preserved in its present state.

— AT the meeting of the Linnean Society, which took place on the 5th inst., there seems to have been something like a free fight. Mr. Carruthers began by proposing that the proceedings of the previous meeting be declared null and void. This Mr. Bentham, the president, refused to put to the meeting. Mr. Carruthers persisted in his motion, and succeeded in carrying a majority of the meeting with him; whereupon Mr. Bentham left the chair, and it is said that he has declared his intention of resigning the presidency. We hope he will think better of this; meanwhile, the temperature of the meeting rose too high to admit of the consideration of scientific questions; and, therefore, such as were to come under consideration that evening had to stand over.

— WE have lately visited Hatfield, the seat of the Marquis of Salisbury, and seen Mr. Cowan's lime-kiln heating apparatus at work. Rarely, indeed, does any novel process turn out so well at first as this has done. The village of glass-houses in the new kitchen garden there is heated by Cowan's apparatus in a thoroughly efficient manner, and at a trifling expense. Mr. Bennett, the gardener at Hatfield, assured us that he has never any trouble, day or night, in securing the efficient heating of all the houses by this means alone. The young gardeners should be well satisfied with the system, as, by its means, they are relieved from all work with fires—work often very harassing and laborious. Like all other innovations, it is, of course, capable of improvement, but no one can see the result already gained at Hat-

field without being satisfied that the Marquis and his able gardener were amply justified in adopting Cowan's system.

— WE hear that the design sent in in competition for Roundhay Park by Mr. Carson, architect, Leeds, has been selected as the best.

— TWENTY-FIVE sets of drawings have been submitted in competition, for the proposed fruit and vegetable markets in Farringdon Street, City.

— GREAT improvement is being made in the Oleander, both as regards the numerous shades of colour and forms of flowers. On the Continent they are being named and distinguished as we distinguish Roses or Dahlias.

— AT this season of the year, when St. Valentine is holding his time-honoured court, it may interest some of our readers to know that tasteful Valentines made of real flowers are now exposed for sale in Covent Garden Market. Arranged in neat boxes, and fringed with lace, these innovations ought to meet with a ready sale.

— IN a letter to the French Society of Horticulture, a chemist, M. Fremont, mentions that a good way of preserving cut flowers in a state of freshness, is to dissolve sal-ammoniac, or chlorhydrate of ammonia, with the water in which the stems are put, in the proportion of five grammes (77½ grains) per litre (1½ pint) of water. They will thus often be kept fresh for a fortnight.

— M. DECAISNE has recently published in the *Bulletin de la Société botanique de France*, descriptions of three new genera of plants gathered in China by the Abbé David. These have been named *Ostryopsis*, *Camptotheca*, and *Berneuxia*; the first belonging to the family of the *Corylaceæ*; the second to the *Nyssaceæ*, and the last to the *Diapensiaceæ*. *Ostryopsis* is a native of eastern Mongolia, and the other two were found in eastern Thibet.

— THE Torrey Botanical Club of New York has issued a Botanical Directory for North America and the West Indies, founded upon one of similar character published some years ago by the Essex Institute of Salem. This embraces the names of all persons in America known to the club as interested in botany, general and special, the names being first printed in alphabetical sequence, and then re-arranged according to the States to which they belong. Such a work as this cannot fail to be extremely useful to students, and the one in question will, doubtless, be eagerly sought after by botanists.

— LARGE quantities of Oranges, says the *Alta California*, are daily arriving at the dépôt at Los Angeles to be shipped to San Francisco. One dealer of San Gabriel sold his Orange crop for 30 dols. per thousand. His Orange grove covers five acres, and contains 500 trees. Estimating these at 1,000 Oranges each, the crop is worth 15,000 dols.; 3,000 dols. an acre in a pretty good return for their cultivation. One acre in Southern California can be made to yield as great a clear profit by semi-tropical nut and fruit culture as twenty to fifty acres in the eastern States devoted to ordinary kinds of farming.

— A PLANT of *Phalænopsis Schilleriana* is now flowering in the gardens at Crewe Hall, Cheshire, bearing 190 fully expanded flowers on one spike. The plant has six leaves, each measuring from 12 to 14 inches in length. Last year the same plant bore two spikes, bearing in all 164 flowers, and, this year, the gardener, Mr. Whittaker, thinking that the two spikes it threw up in the autumn would exhaust the plant too much, rubbed one off, and the other has borne the above enormous quantity of flowers. The only plant, which in any way equals this, is the specimen belonging to Mr. Milne, Yewfield House, Arbroath, N.B., and which has borne about the same number of flowers on a spike. Some of the varieties of this fine winter-flowering Orchid vary greatly in the size and colour of their flowers, and one of the finest and deepest-tinted varieties we have ever seen is now blooming in Mr. Bull's establishment at Chelsea.

— THE annual general meeting of the Royal Horticultural Society was held at South Kensington on Tuesday last, when, after some rather exciting proceedings, chiefly as to the legality of the constitution of the council, their report was adopted by a majority of 231 against 225. The following new members were then elected, viz.:—Lieut.-General Hon. Sir A. H. Gordon, K.C.B., Mr. Joseph Herbert Tritton, Mr. Burnley Hume, and Mr. Henry Webb. The following officers were also elected:—President, the Right Hon. Viscount Bury, M.P., K.C.M.G.; treasurer, Mr. Bonamy Dobree; secretary, Mr. W. A. Lindsay; expenses committee-men, Sir Alfred Slade, Bart., Mr. W. A. Lindsay, and Mr. Henry Little; auditors, Mr. James Nicholson, Mr. John Gibson, and Mr. Robert Hudson, F.R.S. Notwithstanding that the society is considerably in debt, we are glad to learn from the report that increased attention is being paid to the gardens at Chiswick, and that the various instructive trials of vegetables and florists' flowers that have been carried on there, are likely to be continued. We are also glad to hear that the books and accounts of the society have been very carefully kept during the past year, which is reported, on the whole, to have been a somewhat prosperous one.

THE GARDEN IN THE HOUSE.

WINDOW GARDENS IN WINTER.

Most people—especially those who reside in the suburbs of London, or other large towns—are fond of window-gardening during the summer months, but it is rarely one sees a neat and effectively-furnished window-box or balcony in winter. In summer we can keep the window-box outside gay with Fuchsias, Hydrangeas, Pelargoniums, Asters, Stocks, and other showy annuals, but, during the cold season, we must fall back on hardy shrubs, Ivy, Yuccas, and a few winter and spring-flowering bulbs and herbaceous plants, and with tasteful arrangement these are far more attractive than spindly Geraniums or leafless Fuchsias inside the window itself. There is no occasion to keep Geraniums and Fuchsias through the winter, as they always look naked, while bushy little plants can readily be bought for a few pence in spring, when required. People should arrange their balconies or windows for the winter as soon as the bedding plants and hardy annuals are over. For this purpose, we have many hardy shrubs at our disposal, the best being bushy little plants of *Aucuba japonica*, green and variegated Hollies, *Euonymus japonicus*, the gold and silver variegated forms of which are very bright and beautiful. A very effective window-box may be filled with a few simple materials. Common Irish Ivy may be planted at the ends of the box, and trained over a wire hoop, forming a neat arch, which may be varied in height according to the view from the window. The box below may contain a plant of *Retinospora ericoides* or *Thuja aurea*, flanked on either side by sturdy little plants of golden-variegated *Euonymus*. These contrast admirably with the fresh green Ivy above, while the soil in the box may be covered with mossy Saxifrages, *Arabis alpina*, *A. albida*, *A. lucida* variegata, *Aubrietia purpurea*, or the always fresh and green Stonecrop (*Sedum acre*). A few Crocuses, Hyacinths, and Snowdrops, planted in November or December, will brighten up the box during the first sunny days of spring, before it is time to remove the shrubs and insert the ordinary summer-blooming plants and seeds. The Ivy arch may be left during the summer months, and will look pretty partially covered with golden Canary-flower (*Tropæolum peregrinum*) and purple Morning Glory (*Convolvulus major*). Both the last-named plants, as well as scarlet-flowered *Tropæolums* and many other climbers, are readily propagated from seeds sown inside in March, and planted out in the boxes after all danger from frost is past, say, in the middle of May. One of the most effective winter balcony-gardens we have seen for some time is in Portman Square. The front of the balustrades is draped with Ivy, and three or four healthy plants of *Yucca recurva*, in ornamental vases above, complete the arrangement. Nothing could be more effective than this mode of grouping, and the arrangement is allowed to remain all the year round. In summer, the fresh greenness of the Ivy may be brightened up by the addition of a few flowering plants; many are not required with such an elegant arrangement as that just described. Above all things, avoid heavy or crowded grouping, that being not only more expensive, but less artistic and attractive. Simplicity is very often synonymous with elegance, and a few common plants, if beautiful in outline and fresh in colour, will give far more satisfaction to an artistic or intelligent observer than a mass of the choicest exotics clumsily

arranged. Rare and beautiful plants and flowers look well along with suitable surroundings, as in the drawing-room or boudoir, but, for outside window-boxes in the winter months, nothing looks better than the common hardy climbers, shrubs, and herbaceous plants we have here recommended.

F. W. B.

THE INDOOR GARDEN.

A FEW MORE WINTER ORCHIDS.

In addition to the selection of winter Orchids given last week (see p. 117) the following are of great merit, and well deserving of general cultivation for winter flowers.

ANGRÆCUMS.—In this genus we have several noted winter-flowering species, the most attractive being the curious *A. sesquipedale*, which bears drooping spikes of three or four great wax-like flowers, 6 or 8 inches across. Each flower is furnished with a tail-shaped spur, 10 to 15 inches in length, and this gives the star-shaped flowers a weird-like appearance. Good plants bear two or three spikes, but want of numbers is amply made up for in size. One peculiarity about this plant is, that its flowers emit a heavy perfume at night, but their odour is scarcely perceptible during the daytime. It is a native of Madagascar, whence it was introduced to our gardens by the late Mr. Ellis. Other species, as *A. eburneum*, and its greenish small-flowered variety *A. virens*, *A. bilobum*, *A. funale*, *A. citratum*, and the new and rare *A. Ellisii*, all bloom during our dull wintry months. The last-named species is now showing flower in Lord Londesborough's collection, and is remarkable, inasmuch as a profile of the flower resembles a lemon-crested cockatoo. The *Angræcums* (with one exception) all require tropical treatment.

CYMBIDIUM.—At least two of the best species in this genus flower during the autumn and winter months. *C. Mastersii* and *C. eburneum* are well-known plants bearing sub-erect or nodding spikes of white wax-like flowers, amongst their bright grassy foliage. They like a warm humid temperature, and a fresh open compost.

CALANTHES.—These are very useful winter-flowering plants, although their flowers are highly susceptible

of injury during damp foggy weather, such as we have experienced at times during the past winter. *C. vestita*, and its pure white varieties, *Turnerii* and *nivalis*, produce a good supply of flowers during winter. *C. Veitchii* is noted as one of the best of all winter-flowering Orchids, bearing great spikes of its bright rosy-coloured flowers, that contrast well with its pale-tinted congeners. All the *Calanthes* are easily cultivated, the deciduous or pseudo-bulbous section being the best for their winter-blooming qualities, and they also require a more decided season of rest than their evergreen allies.

ONCIDIUMS.—This is a large genus and one that contains many species valuable for their winter flowers. One of the finest of the whole group is *O. macranthum*, a robust grower, even in a low-winter temperature, and it bears great branching flexuose spikes of sixty or seventy flowers. The sepals are of a warm brown, the petals being golden-yellow, while the small dagger-pointed lip is of a bright glossy-purple tint, and the great toothed crest is pure white. It is a native of Peru, and should be in every collection. *O. obryzatum* is another free grower and a most profuse bloomer, bearing numerous golden-yellow fragrant flowers, spotted with brown, on dense flexuose spikes 7 or 8 feet long. Its pseudo-bulbs

A window winter-garden

and leaves are of a fresh and pleasing green colour, and the plant itself grows very freely in a cool *Odontoglossum*-house, a few plants of this species should be grown in every collection, however small, as it is nearly perpetual in its habit of flowering. *O. cheiroporum* is a pretty little free-flowering species of recent introduction, having fresh green leaves and prettily speckled pseudo-bulbs. Its flowers are borne on a dense spike 10 to 12 inches long. *O. incurvum*, *O. serratum*, and *O. Papilio*, are well-known winter-blooming species, well worth growing for variety. *O. cucullatum* is one of the prettiest and most variable of the winter flowerers, and, although not yet generally distributed in collections throughout the country, deserves to be grown everywhere. Several importations have lately been received in good condition, and it promises to become common. It is dwarf and compact in habit, grows freely in a cool winter temperature, and bears spikes of five to seven, rosy-purple or white, crimson or dark purple, spotted flowers. One variety of this species, *O. Phalænopsis*, bears large white flowers spotted with bright purple, and is very attractive. *O. nubigenum* (of gardens), another form, is found on the Andes, at altitudes varying from 10,000 to 12,000 feet. Here, at this high altitude, where radiation is excessive, especially just before sunrise, the plant grows freely.

PHAJUS.—The old *P. grandifolius* is one of the best and most useful of all winter-flowering Orchids, not only for cutting, but also for conservatory decoration. It is one of the oldest and most easily-grown of all Orchids, and may be grown in any ordinary plant-stove. Good specimens bear twenty to thirty spikes, 2 to 3 feet in height, and these are very showy for general purposes of decoration. *P. Wallichii* is a stronger-growing variety, having more yellow on the lip. Both grow well in a moderately rich peaty compost, well drained; and these may be classed among the very few Orchids that are benefited by liquid-manure, or stimulants, at the root. At Chatsworth these plants are grown better than anywhere else we have seen them. *Apropos* of these plants, we may mention that *P. irroratus* (one of Mr. Dominy's hybrids, the result of a cross between *Calanthe vestita* and *P. grandifolius*), has been in bloom in Messrs. Veitch's nursery at Chelsea for the last six or eight weeks. Its flowers are white, suffused with faint rose, and the plant will undoubtedly prove a favourite.

SACCOLABIUMS.—One or two species are very valuable winter-flowering plants; the only drawback to their culture is that they require the heat of an East Indian house, or hot humid plant-stove, to do them justice. Good specimens, with fresh thick leaves, and gracefully-drooping racemes of perfumed wax-like flowers, are very effective for ordinary decorative purposes; a single spike will furnish flowers enough to scent two or three dozen bouquets, and, for button-holes, a single flower or two, mounted on wire and backed by a fresh bit of *Davallia* or Maiden-hair, is all that can be desired. *S. giganteum* is a noble winter-blooming species, the most robust of the whole group, bearing great pendent spikes of white flowers, spotted with rose, and having a violet-tinted lip. It may be grown either in a pot or basket, or small plants do well on a block suspended near the light.

CYPRIPEDIUMS.—One of the best of the winter-blooming *Cypripedes* is *C. villosum*, a vigorous grower, bearing great brown flowers, which shine as brightly as if varnished. *C. barbatum* sometimes bears a few odd flowers during the autumn and spring, but cannot be relied on for blooming. *C. Harrisianum*, a hybrid between the two above-mentioned species, is a valuable bloomer for all seasons, and the new *C. Sedeni* is the brightest-coloured variety in cultivation, and a most profuse bloomer during the autumn and winter months. Plants of this last have been blooming in the Royal Exotic Nursery, Chelsea, for the last four or five months, and the rosy flowers are very bright and effective among white-flowered plants of other genera. *C. longifolium* flowers all the year round, the rosy-petalled flowers being borne one at a time on a ten or twelve-flowered spike, and each flower lasts quite a month in perfection. *C. Roezlii* appears to be a strong-growing form of the last, and blooms in the same manner. Both are variable in the colouring of their flowers, and deserve a place in every collection, as, in addition to the flowers, their foliage is of the freshest description, and of an elegant drooping character. All the above grow well in a warm greenhouse

or *Cattleya*-house, where the minimum temperature does not descend below 50° in winter. A fresh, open, well-drained compost of fibrous peat and living *Sphagnum* suits them admirably, as their thick hairy roots revel in the Moss when it is alive; and as a surfacing material for Orchid pots nothing is equal to green *Sphagnum* fresh from the bogs or marshes.

LÆLIAS.—In addition to the beautiful *L. anceps* mentioned last week, we have several other species well worth general cultivation for their winter flowers. *L. albida* and its rosy-lipped variety, *L. acuminata*, *L. purpurea*, and the never-failing *L. autumnalis*, should find a place in every collection. The latter plant does well in a pot or on a block suspended near the light, and we have seen it grown and flowered to perfection in the moderately dry and airy atmosphere of a common Vinery. If there is the convenience of a *Cattleya*-house proper it will be found the best position for these beautiful plants, but if not, try them in a warm Vinery during winter, and let them take their chance; as to summer temperature, take the precaution to keep them well supplied with tepid moisture, either by immersion or by frequent syringings overhead.

PLEIONES.—These little Alpine Orchids are merely deciduous *Cœlogynes*, and, as a rule, flower late in the autumn months. *P. Wallichiana* (*P. præcox*) is the earliest species, its rosy-lilac flowers appearing about October or the beginning of November. *P. lagenaria* and the white-petalled *P. maculata* follow in quick succession, and form the grand show of the Pleione or Indian Crocus season. The rare and pretty little *P. humilis* is last, and we saw a nice little pan of this in full flower the first week in February. The culture of these delicate little Orchids is simple. They must be potted in a fresh well-drained compost of fibrous peat, chopped living *Sphagnum*, and leaf-mould as soon as they commence their growth, which is during the winter months, and generally a week or two after their flowers fade. The bulbs should be well elevated above the rim of the pot or pan, and grow best placed on a shelf in a moderately warm humid temperature near the light. A shelf in the early Vinery suits their requirements exactly, as an occasional syringing does them good and keeps down insect pests, to which their succulent and somewhat tender foliage is subject. The flowers of all the species are universal favourites, and come in very useful for bouquet work at a season when choice flowers are scarce. Pleione flowers should never be cut, but gently pulled from the inflated sheath from which they generally spring in pairs.

ZYGOPETALON MACKAYI.—This is a good old winter-flowering Orchid, and one that seldom fails to flower every winter, even when badly treated. Good specimens in pots bear numerous spikes of delicately-tinted flowers. The great flat lip is white, curiously marked with diverging lines of purple hairs. The spikes are handy for cutting, and look well in the drawing-room vase; the individual flowers are too massive for bouquet work. This plant commences to grow in January or February, and does well in the early Vinery if well supplied with tepid water, and placed near the light.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Climbers for Plant-stoves.—I grow, for the sake of their foliage, *Cissus discolor*, *Vitis gongyloides*, and *Batatas paniculata*. The *Vitis* has a novel tropical appearance, and sends out slender aerial roots from 5 to 8 feet long, which droop gracefully amongst the other vegetation. As regards flowering climbers, nothing surpasses *Stephanotis floribunda* (white), *Dipladenia amabilis* and *D. insignis* (deep rose), *Allamanda Hendersonii*, and *A. grandiflora* or *A. nobilis* (yellow). For winter, a few plants of *Tropæolum Lobbianum* may be trained on wires or strings near the glass, and will flower freely. *Rondeletia speciosa* is another valuable winter-flowering stove-plant that does well treated as a climber. All these may either be grown in pots or planted out, both plans having their special drawbacks as well as advantages. In either case use a fresh open compost of peat, fibrous loam, leaf-mould, and sand.—B.

Ferns for Bouquets.—What are the best half-dozen Ferns to grow for cutting for bouquets, button-holes, and similar decorations? I already have *Adiantum cuneatum* and *Pteris serrulata*, and I wish to have as much variety in the way of form as I can.—Q. [The Ferns just named are two of the best you can employ for bouquet work. Of *A. cuneatum* there is an elegant variety, named *A. gracillimum* (elegantissimum) a kind with finer fronds than those of the species; and there is, also, a variety of *Pteris serrulata*, the divisions of which are finely crisped. Several of the *Davallias* are useful for such work and last long in good condition in a cut state, especially if dipped in water before they are used. Of these, the best are *Davallia bullata* and *D. dissecta*, but the common Hare's-Foot (*D. canariensis*) and *D. elata* come in very usefully for such purposes. *Adiantum Farleyense*, *A. Capillus-Veneris*, *A. tenerum*, *A. tinctum*, *A. colpodium*, and *A. assimile*, all yield good fronds for bouquet-making.—ED.]

THE FLOWER GARDEN.

A HARDY PELARGONIUM.

The plant which we figure below, and which is known as *Pelargonium Endlicherianum*, was first discovered in the south of Asia Minor by the German botanist Kotschy in 1842, and, for many years, was known in Europe only from the dried specimens of it which he presented to a few herbariums. In 1856, however, M. B. Balansa, during one of his frequent visits to Asia Minor, conceived the idea of introducing it into cultivation, and, on his return to France, brought with him several living plants, some of which he presented to the garden of the Muséum, and some to M. Pelé, an eminent nurseryman of Paris. The plant, thus, for the first time, brought under culture, has proved an important acquisition to our gardens, as, in addition to being the only hardy *Pelargonium* we are yet acquainted with, it is also remarkably handsome and singular in appearance. It belongs to the section of the genus *Pelargonium* known as "*Jenkinsonia*," the peculiarity of which consists in the flowers having only the two upper petals fully developed, the three lower ones being merely rudimentary, and scarcely visible. The subject of our notice grows from 12 to 20 inches high, sending out several stems from its branching rhizome, and the entire plant is covered with a light velvety pubescence. The lower leaves are of a rounded reniform shape, notched and toothed, and of a greyish-green colour; those of the stem are more or less deeply divided into from three to five lobes. The flowers, which appear from the end of June until August, are large, of a fine purplish-rose colour, each petal being marked with five longitudinal veins of a darker shade. The three lower and undeveloped petals are of a whitish hue and are only about half the length of the divisions of the calyx. As regards its culture, it requires a well-drained sandy soil (but not too light), and a warm and sheltered position. The chief care which it demands is to be preserved from damp, of which it is more impatient than of cold; an excess of moisture invariably proving fatal to it. If this one point be observed, its culture is by no means difficult. It is easily propagated either by means of cuttings, or from seed, which it yields freely. In conclusion, we may add that the plant received its specific appellation from the German botanist Fenzl, who named it in honour of his friend Endlicher, and who has described it in his '*Pugillus plantarum novarum Syriæ et Tauri occidentalis*.' It was first brought to England by Mr. Wm. Robinson, but is as yet rare. On light warm soils in the South of England it will prove a showy perennial. The illustration is a faithful portrait of the plant in its first year.

W. M.

A hardy *Pelargonium*.

in the open borders at the end of April or beginning of May, but will not then flower so early.—*Tender Annuals*, a very limited class, will also vegetate in a close frame, but require more warmth to bring them to perfection than the preceding; they should, after pricking out, be transferred to a second hot-bed, and will flower most satisfactorily in the greenhouse or window.—*Hardy Perennials*, of the commoner and large-seeded kinds, may be sown in the open borders any time from March to August, but the rare and more delicate species will succeed with greater certainty if raised in a close frame, with or without bottom-heat; thus treated many will flower the first season, if sown early and planted out in the borders in May. All those with very small seeds should be sown in pots under glass. The amateur will do well to bear in mind that, though many perennial seeds vegetate as quickly as those of annuals, there are some others which usually remain dormant for weeks, or even months; to this class belong the *Gentians*, *Cyclamens*, *Pæonies*, *Fraxinella*, many

Australian *Leguminosæ*, and especially North American plants. Most of these require, in fact, to be sown in autumn as soon as gathered, and they will then vegetate the following spring. As this is not always practicable, the plan of steeping the seeds before sowing, for twenty-four hours, may be adopted with great advantage in many cases.—*Half-hardy Perennials* require the treatment of the half-hardy annuals, differing only in their need of winter protection.—*Stove Seeds* need a moist elevated temperature, such as the stove or forcing pit affords; and greenhouse seeds succeed well under the same conditions; in their absence the latter are best raised in a good hot-bed.—*Biennials* may be sown in the open ground in spring and summer, not later than June and July, the seedlings being planted in autumn, where they are intended to bloom the following season. The half-hardy plants of this class, as *Ipomopsis*, should be pricked out in pots that they may be protected in winter.—All seeds sown in frames or pits require shading with tiffany or thin calico, in bright weather during the middle of the day, especially as the spring advances. In the open ground, seeds should not be sown too early: there is great risk of failure before the end of March; where early flowers are desired of annuals, it is better to sow in autumn. For all seeds in pots, a compost of finely-pulverized leaf-mould, peat, or other vegetable soil, with one-third its bulk of sand or very sandy-loam, will answer well; sow very thinly; let the pots be well drained; cover the seed with about its own thickness of soil, and thin out crowded seedlings early. After germination has once commenced, the surface of the soil should on no account be suffered

to become dry. Very small seed, such as *Mimulus*, *Lobelia*, *Calceolaria*, &c., should not be covered with soil, but be sprinkled thinly on the soil which should be previously watered from a fine rose. Chinese *Primula* germinates best when covered with a layer of damp Moss; this seed often fails to grow from being too deeply covered with soil, and many other failures are attributable to the same cause.

WM. THOMPSON.

BEDDING CALCEOLARIAS.

I AGREE with your correspondent, "R. D." (see p. 77), that mismanagement has much to do with the so-called disease in *Calceolarias*. In a garden, of which I had charge during the summer of 1872, I had no disease, while, owing to the excessive wet, assisted by unhealthy plants, few, if any, of my neighbours' *Calceolarias* escaped. In this district it is not considered judicious to put in cuttings in July or August. I never put in any till the first week in October, when nice fresh juicy cuttings may be obtained, and not

HINTS ON THE MANAGEMENT OF FLOWER SEEDS.

Hardy Annuals are best sown in the open border in light soil, from March till June for summer and autumn flowering; and in September for flowering the following spring.—*Half-hardy Annuals* require to be sown in March or April, on a gentle hot-bed, or in a close frame without bottom heat, the latter mode succeeding perfectly, unless the seeds are sown too early in the season; many of them may even be sown

flower-spikes, as must be the case earlier in the season; old potting-bench materials may do for soil, but I find light loam, leaf-mould, and river-sand, in equal parts, much better. A cold frame is most decidedly the best place in which to put them, and the sooner the cuttings are put into the soil after their removal from the plants the better. I do not agree with "R. D.'s" practice of drying them in the sun. After the frame is full and watered, put on the lights, which should be kept close and shaded with scrim for the first fortnight. Then remove the scrim, but keep them still close for another fortnight. Admit air gradually at first; then give abundance of it on every favourable day. No water will be required till the end of February, and, if the winter has been mild, the plants will have been topped several times, but, if it has been severe, protection must have been resorted to. In the first week of March I transplant into prepared frames; the soil used being light, but richer than that used before. The plants are put in, 5 inches apart, each way, watered, and kept close for two or three days; air is then admitted as usual. In the first week of April I again transplant them 9 inches apart, each way, in prepared soil, 7 or 8 inches deep. After keeping them close for a day or two, to induce them to take to their new quarters, the sashes may be removed every fine day, and nights too, if there is no frost. By the second week of May, when I generally plant them out, they are nice bushy plants, with good balls. Plants treated thus suffer but little from disease. "R. D." might have mentioned, when giving his selection of kinds, Sang's Ambassador, which is the best crimson Calceolaria in cultivation, while the old Aurantiaca is still one of the best among yellows, it is hardy, free in growth, and stands rain well.

JAMES SIMPSON.

CLASSIFIED LIST OF ALL THE KNOWN CROCUSES.

By J. G. BAKER, F.L.S., Assistant Curator of the Kew Herbarium.

THE following is a classified synonymic list of all the known Crocuses, with their native countries.

Sub-genus 1. Holostigma.

Style divided into three entire stigmas.

SPRING-FLOWERING SPECIES.

1. *C. chrysanthus* (Roumelia and Asia Minor), syns., *C. annulatus*, var. *chrysanthus*, *C. croceus*, *C. sulphureus*.
2. *C. mœsiacus* (Banat, Greece, Asia Minor), syns., *C. vernus*, *C. luteus*, *C. floribundus*, *C. lagenæflorus*, var. *luteus*, var. *aureus*, *stellaris*, *sulphureus*, and *lacteus*.
3. *C. gargaricus* (Asia, Minor), syn. *C. Thirkeanus*.
4. *C. susianus* (Crimea), syns. *C. revolutus*, *C. reticulatus*, *C. Roegnerianus*, var. *immaculatus* (Constantinople), *Ancyrensis* (Asia Minor).
5. *C. biflorus* (south Europe), syns. *C. circumscissus*, *C. annulatus*, var. *biflorus*, var. *ragenteus* (Central and Northern Italy), *pusillus* (southern Italy), *Adami* (Caucasus and Crimea), *Weldeni* (Dalmatia), *nubigenus* (Asia Minor).
6. *C. versicolor* (south-west France), syns. *C. fragrans*, *C. cress-tensis*, *C. Reinwardtii* (?).
7. *C. suaveolens* (south Italy).
8. *C. minimus* (Sardinia and Corsica), syns. *C. insularis*, *C. corsicus*, *C. nanus*.
9. *C. banaticus* (Mountains of Hungary, Transylvania, and Croatia), syns. *C. Heuffellii*, *C. Heuffellianus*, *C. vittatus*.
10. *C. vernus* (Central and Southern Europe, from France to the Crimea), var. *albiflorus*, *obovatus*, *nivigenus*, *Tommasinianus*, *nervifolius* (?).
11. *C. Sieberi* (Greece, Crete, and Asia Minor), syns. *C. nivalis*, *C. Sieberianus*, *C. sublimis*, *C. Sibthorpianus*, var. *Atticus* (Greece), *Veluchensis* (Greece and Transylvania), *exiguus* (Transylvania).
12. *C. carpetanus* (Spain).
13. *C. reticulatus* (Caucasus, Asia Minor, Austria), syns. *C. variegatus*, *C. reticulatus*, var. *variegatus*, *C. macranthus*, var. *albicans*, *Dalmaticus* (Dalmatia), *Etruscus* (Tuscany).

AUTUMN-FLOWERING SPECIES.

14. *C. sativus* (Italy), syns. *C. Orsinii*, *C. Häussknechtii* (Kur-distan), *C. intromissus* (Damascus) (?).
15. *C. Cartwrightianus* (Greece).
16. *C. Pallasii* (Crimea).
17. *C. Thomasii* (South Italy), syn. *C. Thomasianus*.
18. *C. Visianicus* (Dalmatia), syn. *C. Pallasii*, *C. hybernus* (Roumelia) (?).
19. *C. hadriaticus* (Albania and Ionian Islands).
20. *C. Cambessedesii* (Majorca), syn. *C. Cambessedesianus*.
21. *C. lazicus* (Asia Minor).
22. *C. peloponnesiacus* (Greece).

23. *C. Kotschyanus* (Mountains of Cilicia), syns. *C. zonatus*, *C. Karduchorum* (?).

24. *C. Scharojani* (Western Caucasus, 6-7,000 feet.)

Sub-genus 2. Odontostigma.

Style divided into three stigmas, which are fringed or cut at the tip.

SPRING-FLOWERING SPECIES.

25. *C. Olivieri* (Greece), syns. *C. lagenæflorus*, *C. Aucheri*.
26. *C. Suterianus* (Anatolia), syn. *C. chrysanthus*.
27. *C. aleppicus* (Aleppo).
28. *C. ærius* (Mountains of Armenia, 6-7,000 feet), syn. *C. Sibthorpianus*, var. *stauricus*, var. *pulchricolor* (Bithynia).
29. *C. Imperati* (south Italy).

AUTUMN-FLOWERING SPECIES.

30. *C. longiflorus* (Sicily, Calabria), syn. *C. odoratus*, *C. serotinus*, var. *Melitensis* (Malta).
31. *C. serotinus* (Portugal) var. *Salzmanni* (Tangiers).
32. *C. caspius* (south shore of the Caspian).

45. *C. speciosus* (Hungary, Transylvania, Crimea, Caucasus), syn. *C. multifidus*.
46. *C. pulchellus* (Turkey in Europe, Greece).
47. *C. byzantinus* (Banat, Transylvania, Wallachia), syns. *C. iridiflorus*, *C. banaticus*, *C. speciosus*, *C. Herbertianus*, *Crociris iridiflora*.—*Journal of the Royal Horticultural Society*.

The Virginian Stock.—This is one of the hardiest of hardy annuals, and it will grow anywhere, either on a wall or a hard gravel path. Within a short distance of where I am writing, there is a broad band of this Stock now in full flower, growing in front of a cottage, on the edge of a gravel path close up to the building. I have noticed it in the same spot when passing for the last four or five years at this season, or soon after, coming regularly into bloom, and continuing to flower beautifully all through the spring. After it has done flowering, the seeds ripen and fall, the dead roots and branches are cleared off, and the gravel made tidy with the rake; and regularly, early in the autumn, a new crop springs up. The position is warm and sheltered, otherwise it seems to have had scarcely any attention. There are many bare untidy corners—not only in front of cottages, but many buildings of a more ambitious cast, which might be beautified in this or some similar way at a very trifling expense.—E. H.

Various-flowered variety of St. Dabeoc's Heath.—Some few weeks since we met with, in the Knap Hill Nursery, a variety of St. Dabeoc's Heath (*Dabeocia polifolia varicolor*) remarkable for the dissimilarity in the colour of its flowers. The plant, which is perfectly hardy, forms a cushion-like, low, evergreen shrub, suitable, from its habit, for associating with such plants as hardy Heaths. Its chief peculiarity, however, is that its flowers are sometimes purple, sometimes white, sometimes of various intermediate shades of bluish-white, pallid-purple, or pink. In the majority of cases, the spikes bear flowers uniform in colour, all purple, all bluish, or all white, but these are so mixed up on the plant, that it appears as though two or three varieties were accidentally associated in the tuft. That

they all spring from one source is, however, abundantly proved, by the fact that, from time to time, and not unfrequently, there appears a spike on which both pure purple and pure white flowers are associated, or even, sometimes, may be seen flowers in which one-half the tube is white and the other half purple. Mr. Waterer has grown it for some years, with the view of testing the permanency of its character—which does not vary in the least.—*Florist*.

THE BANNAT GLOBE THISTLE.

AMONG the taller and more vigorous-growing plants which are seen to most advantage when growing amongst kindred subjects at the back of a border, or fringing the margin of a shrubbery, or isolated in an open space, few are more effective than the bold hardy perennial to which we here devote a few lines of description and recommendation. Some of our readers, are, no doubt, familiar with it (for it is a plant of no recent introduction), but to those who are not, we may describe it as a sturdy Thistle-like plant, of stiff and slightly branching habit, growing from 2 to 3 feet high, or more, with large, deeply-cut, spiny leaves, of a dull green colour on the upper surface, and white and cottony beneath. The flowers are borne erect on the ends of the branches, and are arranged in large, symmetrical, spherical heads, as shown in the illustration. They are of a fine azure-blue colour, and their effect is heightened by the delicate amethyst tint of the involucre, the bracts, and the upper part of the flower-stalks. The culture of this plant demands no particular instructions. As in its native habitats it flourishes in the most arid, wild, and unpromising places, so does it appear quite indifferent as to what kind of soil, or what position it may meet with in our gardens, and will not only live, but thrive, without even the common attention of watering,—a hardy, self-contained plant, with an unusual amount of vitality stored up in its rugged root-stock. Insensible of neglect, it presents, with its bold port, gracefully-cut leaves, and handsome flowers, one of the finest sights our gardens can boast of from June to August. It can be readily propagated either from seed, or by means of the underground shoots or runners which are emitted in great numbers from the root-stock. Native of the Bannat Mountains, in Hungary. This plant is sometimes sold under the name of *E. Ritro*; the latter, however, is a much dwarfer species, with flowers only one-fourth as large as those of *E. Bannaticus*, and is, on the whole, a rather insignificant plant, while, as we have before stated, *E. Bannaticus* is a very ornamental one.

Gaillardia amblyodon.—The genus *Gaillardia* is well known to include some of the most popular border plants, equally valuable from their long blooming qualities, as dwarf bedders, or for furnishing cut flowers. The *G. amblyodon* has proved itself to be a very desirable and distinct addition to the older species, of the easiest culture and a most abundant bloomer. It grows to the height of 2½ feet, but commences flowering when little more than a foot high, each plant forming a dense bush, above which the flower-heads are elevated on rather long foot-stalks. The foliage does not differ

materially from that of *G. picta* and its varieties, but is more undulated and of a lighter green colour. The flower-heads are from 2 to 2½ inches across, and differ notably from those of *G. picta*, in the ray florets being more numerous, in the uniform deep cinnabar-red colour, which deepens to purplish-brown at the base, and in the scales of the involucre being narrowly linear, arranged in three or four series, with spreading leafy tips. The disk florets are of a very deep blackish-purple colour, except those of the immediate centre, which are orange-yellow. It requires only the ordinary treatment of half-hardy annuals, and succeeds in any light soil.—W. THOMPSON.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Dianthus saxicola.—Few additions have been made of late years to the list of cultivated species in this genus, so that a new one will, doubtless, be welcome to the lovers of the variety. It is a desirable and distinct plant, succeeding well in the open border. It forms vigorous tufts of linear, pointed, slightly glaucous, foliage, 6 inches in length, from which arise stems about one foot in height, bearing numerous rather large flowers of a delicate rosy-flesh colour, free from markings of any kind.—W.

Sisyrinchium grandiflorum.—This charming plant with its lovely purple bells has been blooming here, in the open air, for some time. It is one of the best plants with which I am acquainted for a cool house or pit. All the *Sisyrinchiums* are interesting, many of them being very hardy, as well as beautiful, *S. odoratissimum* is delightfully fragrant. They only require to be better known to be appreciated.—J. MORLEY.

Romneya Coulteri.—This interesting novelty, received direct from California, is described by the collector as having very large handsome white Argemone-like flowers, 5 inches across, slightly fragrant, the stems being about 4 feet in height, and the foliage variously divided. It belongs to the Papaveraceæ or Poppy worts, and in the "Treasury of Botany" is represented to form a connecting link between them and the Nymphæaceæ and Sarraceniaceæ. It is probably of perennial duration, and possibly hardy, but on that point experience is wanted.

Lathyrus Sibthorpii.—This is remarkable among perennial Lathyruses for the early period at which it blooms, and no less so for the tender rosy-purple or deep mauve colour of its flowers. In habit it is dwarf compared with *L. latifolius* and its varieties, not often exceeding 3 feet. In very young plants the merits of this species are not so evident, but when thoroughly established in good loamy soil, it forms one of the greatest attractions of the spring border. It is a native of Greece, and was introduced thence by the illustrious Professor, whose name it bears, to the Botanic Gardens at Oxford.

Linum Berlandieri.—This is a very dwarf species, not exceeding 6 or 8 inches in height, forming a tuft with numerous spreading stems, the flowers being produced in terminal corymbose racemes, with a corolla about an inch across when fully expanded, of a buffy-yellow colour, which, at the base, deepens to Orange. It blooms from July to near the close of the summer. A native of Texas. It has been treated as a half-hardy annual, but may possibly succeed if sown in open ground in sandy soil.

As, however, it makes very long roots, transplantation will be facilitated by sowing in pots.

Solanum rostratum.—The species of *Solanum* now in cultivation are already numerous, but the present one is sufficiently distinct in its character to obtain for it the suffrages of many amateurs. It is an annual plant of about 2 feet in height, remarkable for having both surfaces of the leaves, as well as the stem, and calyces covered with straight yellow spines or prickles. The foliage is pinnatifid, and thickly set with greyish stellate hairs. The flowers are large, of a showy yellow, and pilose externally. It is a native of the Colorado Plains, and requires only the treatment of the other half-hardy annual species.

Oenothera serrulata.—Notwithstanding the number of the species of this genus which are already cultivated in gardens, it will be admitted that there is still room for good annual species of dwarf habit, and devoid of the coarseness of foliage possessed by so many otherwise desirable plants. The *O. serrulata* combines with both these requirements large bright yellow flowers, produced throughout the season. It grows scarcely more than a foot high, and commences flowering when but little more than half that height, the plant being of bushy growth, and clothed with neat lanceolate, serrulate foliage. The flowers have the great advantage of being diurnal, and of remaining open several days. It is a native of Texas, and has been treated as a half-hardy annual, but may succeed sown in the open border with subsequent transplantation.—W. THOMPSON'S Catalogue.

Echinops Bannaticus.

THE GARDENS OF ENGLAND.

THE ABBEY GARDENS, BURY ST. EDMUNDS.

THESE attractive and really beautiful grounds consist of some 13 acres, and are usually designated the Botanic Gardens, an appellation, however, to which they are hardly entitled; for, although they contain many rare and interesting plants, no attempt would appear to have been made to effect anything like scientific arrangement. They are, however, exceedingly interesting to the horticulturist, as well as to the antiquarian, occupying, as they do, the ancient site of the Abbot's Palace and Court. The grounds throughout are interspersed with portions of the picturesque and Ivy-clad ruins of that vast monastic establishment, which was founded about the year 637 by Siegebercht, the first Christian king of East Anglia. The principal entrance to the gardens is by the Abbey gate, on Angel Hill; and this was also in former times the chief entrance to the monastery, and opened into the great court before the Abbot's Palace. The gate-house is some 50 feet long by 40 feet wide, and is 62 feet high. It is considered to be one of the purest specimens extant of the decorated style of pointed architecture, the tracery, &c., displaying the most exquisite workmanship. Its erection was commenced during the year 1327, and was completed about 1377, and appears to have combined the strength of a fortress with the beauty of a highly ornamented gate-house. The strong hinges of the massive iron outside gate, the groove for the portcullis, and stations for archers, &c., being still to be seen; and all this precaution would appear to have been really necessary, as the former gateway, which this had replaced, was destroyed during an *émeute* of the townspeople in the year 1327. The site of the gardens is now the property of the Marquis of Bristol, and the idea of forming a garden upon the spot was first conceived by the late N. S. Hodson, Esq., an excellent practical botanist, and an enthusiastic horticulturist, who brought his valuable collection of rare plants to this place about the year 1831, where he would appear to have really contemplated the formation of a scientific or botanical establishment. But this idea he appears to have ultimately abandoned in favour of the more ornamental and fashionable style of embellishment, which was about that time coming into public favour. From the gate-house just mentioned, a broad gravel walk or promenade, 16 feet wide, extends eastward until within some 70 yards of the margin of the river Lark, and this walk is intersected by another of less width, which leads from a grassy mound on the south, which covers and protects some extensive ruins, and extends towards the northern parts of the grounds, where it branches into other walks or promenades, and, with the point of intersection of these two walks for a centre, a circle is described, and defined by a gravel walk enclosing an area of exactly an acre in extent; and this is laid out as a flower-garden in the form of a series of concentric flower-beds, separated from each other by broad belts of fine green sward, in these are grown, during the summer months, most of the finer sorts of bedding and other plants, arranged in the most tasteful manner; while in spring they are occupied by spring-flowering plants and bulbs, of which the gardens contain an extensive collection. On passing through this circular group of gay flower-beds, an extensive ruin will be observed on the right, and within a short distance of the broad walk. This is now known as the "Abbot's Parlour," and is a portion of the Abbot's Palace—probably the dining hall. The palace would appear to have occupied the entire eastern side of the great court, communicating with the conventual buildings on the south, and the various offices, dungeon, or prison of the monastery on the north. Among the crumbling ruins of the so-called "Abbot's Parlour" are several fine specimens of the common Horse Chestnut (*Æsculus Hippocastanum*), which are evidently self-sown, and of considerable age, together with several Lime-trees (*Tilia rubra*), while on the left of the broad walk, and in the line of the palace ruins, stands also a fine example of the true English Elm (*Ulmus campestris*), the noble trunk of which is enclosed by a circular seat, where, during the summer months, under the deep shade of its umbrageous boughs, visitors find an agreeable resting-place. These fine trees are all in luxuriant health although their

naked roots are, in many instances, worn and excoriated by the busy feet of children and numerous visitors. On reaching the eastern extremity of the promenade, between it and the river, will be observed a hexagonal turret or tower, near some ruined and Ivy-clad arches. This is known as the "Dove Cot," but would appear to have been a place of defence of some sort, as there are still to be seen the stations and apertures for archers, and it fully commands the south side of the Abbot's Bridge, an ancient mural structure of three arches, supposed to have been built about the year 1148. It spans the river at the northern extremity of the grounds, and appears to have been the principal means of communication between the monastery and the ancient Vineyard of the establishment, some six or more acres in extent, and lying pleasantly upon the east bank of the river Lark, which separates the same from the gardens. On the east side, the Vineyard, or the Vine-fields as they are now called, are enclosed by a strong ancient wall, which is still in a good state of preservation. There are also still to be seen distinct traces of terraces, &c., and some kinds of herbs, such as the Alexanders (*Smyrnum Olusatrum*) so much cultivated in ancient gardens, but now entirely neglected, are frequently to be seen here. It was also here that the Royal Horticultural Society of London, in 1867, held its first provincial meeting. On the banks of the river are some very fine, large, and apparently very old Willow-trees, one of which was known as the "Abbot," and was unfortunately prostrated during a gale of wind some few years since. There are also some very fine specimens of the black Italian Poplar, which were, however, so severely injured during the memorable winter of 1860, that they have not even now recovered from the effects of the frost. A little to the north of the Ivy-covered turret, now called the "Dove Cot," was formerly the "Bath," which was 20 yards square, and divided into several apartments, through which the little rivulet called the Linnet was made to flow on its way to join the Lark near the Abbot's bridge. This junction is now effected at a point some half mile to the south.

The ruins under the grassy mound just mentioned are supposed to be those of the dormitory and library, &c., of the monks, while the ruins to the south of this mound are those of the refectory, or the great dining-hall of the establishment. In this apartment sat the Parliament of 1446, presided over by King Henry VI. in person. To the west of this, on the south side of the gate-house, was the strangers' hall and almonry for the entertainment and relief of strangers and pilgrims; while to the south-east of this mound are the interesting ruins of the church of St. Edmund, which was built about the year 1395. The walls are of rubble, and of immense thickness, and the mortar has acquired great power of resistance, and almost the hardness of granite itself. They have also been cased with hewn stone, apparently from the quarries of Barnack in Northamptonshire; and in this church was preserved the sacred shrine of St. Edmund, before which kings were wont to lay aside their crowns, and to supplicate the aid of the so-called martyr. Against the Ivy-clothed ruin of one of the lofty piers are now fixed tablets recording the connection of this interesting spot with Magna Charta.

On entering the gardens by the Abbey gate, and turning to the left, a broad walk will be found running parallel with the northern boundary wall of the monastery, which is still in good preservation, although the native yellow Wallflower (*Cheiranthus fruticulosus*) finds upon its crumbling surface an appropriate and congenial home. To this wall are also trained various climbing plants, such as the *Glycine sinensis*, the *Jasminum revolutum*, *nudiflorum*, &c., while, abutting also upon it are sundry detached lean-to glass structures, which are devoted to the culture of various varieties of tender plants, and are arranged on each side of an ornamental-fronted summer-house. One of these structures is devoted to the culture of exotic Ferns, another to that of Succulents, of which a goodly collection is cultivated, and some of which are exceedingly large, and fine specimens of these curious-looking and interesting plants, the culture of which has, of late, become more fashionable than formerly. There is also a small, but good, example of "Beard's Patent Metallic Houses," devoted to the growth of flowering-plants of various sorts, for which purpose it is admirably suited, being light, elegant, and strong, together

with various other glass erections, span-roofed as well as lean-to, for the accommodation and propagation of bedding and other plants. Near to one of the glass structures, upon a border sloping towards one of the principal walks, was a creditable example of the "carpet style" of planting beds and borders; and, in this instance, the material used was composed principally of the *Echeveria secunda glauca* and *metallica*, *Sempervivum californicum*, *Sedum glaucum*, the various sorts of *Alternanthera*, and the golden Feverfew. The various clumps of ornamental trees and shrubs are all margined with hardy herbaceous plants and spring-flowering bulbs; while specimens of rare trees and shrubs are also tastefully distributed throughout the grounds, conspicuous amongst which is a fine specimen of the *Ailantus glandulosa*, or Tree of Heaven, so called on account of its lofty growth. This tree was transplanted to the spot it now occupies, when of considerable dimensions, about the year 1831, and is now some 80 feet in height, and is a finely-formed tree. It stands to the right of the promenade when entering the gardens by the Abbey gate, while on the left is a plant of the Valonia Oak (*Quercus Ægilops*), or the "Trojan Oak," as it is called here, the Acorn from which it sprung having been picked up fifty years ago on the banks of the Simois, in the breezy plains of classic Troy, by the Rev. Arthur Young, nephew of the celebrated writer on Suffolk agriculture. This species of Oak was introduced into this country from the Levant so early as the year 1731, but does not appear to have taken kindly to the soil and climate of the British Isles, and is still scarce, although, on account of the great value of its bark, attempts have been made to naturalise it, but, hitherto, those attempts have not been attended with success. The Acorn cups are shaggy, and bear a fanciful resemblance to the face of a goat, hence its specific name. They are also said to be fully as rich in tannin as the bark itself; but out of a bushel of Acorns sent to this country by Mr. Young only about eighty germinated, although they were gathered when quite ripe and falling, and were packed and transmitted to this country with great care. Still, it is quite possible, that they may, to some extent, have become heated during their transit, and their germinative power, consequently, impaired. Of the plants raised from the Acorns thus sent by Mr. Young, one was planted in the gardens here, where it continued to thrive, until the terrible winter of 1860-61, when it was so severely punished that it has not even now recovered from the effects of the same. It still, however, exists, and is regarded as a living and interesting memento, not only of a locality famed in Homeric story, but, also, of the author of the "Annals," whose writings and character were so universally esteemed. Near to this Oak is a fine plant of the curled-leaved Elm (*Ulmus crispa*), and various species of the Lime-tree, such as *Tilia heterophylla* and *parvifolia*; the cut-leaved Beech (*Fagus incisa*), and many other beautiful and interesting trees and shrubs. The soil or the situation, however, does not appear to be well suited to the growth of Conifers, although the grounds contain some good specimens of the Austrian Pine, also some thriving young plants of the *Wellingtonia gigantea*, which appear to be at home in all sorts of soils and situations. Near the northern boundary of the grounds, and contiguous to the Abbot's Bridge, before alluded to, is the residence of the present lessee of the gardens, Mr. Pettit, to whom the greatest credit is due for the admirable manner in which he keeps the gardens; and for the facility which he affords to the inhabitants of the town and neighbourhood to enjoy the same, as well as for his courtesy and attention to visitors.

P. GRIEVE.

Calla palustris in Surrey.—*Calla palustris* was originally planted in North Surrey so far back as 1861, and is now quite established. I have no doubt that this is Mr. Gardener's station. It is also one of the plants recommended for naturalisation in "Alpine Flowers" (p. 102):—"It is thoroughly hardy, and though often grown in water, likes a moist bog much better. In a bog, or muddy place, shaded by trees to some extent, it will grow larger in flower and leaf, though it is quite at home, even when fully exposed. Those having natural bogs, &c., would find it a very interesting plant to introduce into them, while for moist spongy spots near the rock-garden, or by the side of a rill, it is one of the best things that can be used.—R. A. PRYOR, in *Science Gossip*."

GARDEN DESTROYERS.

MEALY BUG.

It is well that this insect is principally confined to such plants as are grown in heat, or it would render the cultivation of many things well nigh impossible. The insect will certainly live even through the winter on greenhouse plants; but here it increases so slowly and spreads so little, that it does not do much harm, further than there is always danger, when stove and greenhouse plants are mixed somewhat for decorative purposes (as they frequently are in the summer season), of the bugs getting from any infested greenhouse plants that happen to come in contact with the occupants of the stove. The worst circumstance connected with mealy bug is, that it does not alone exist upon plants, but, where it is allowed to get to a considerable head, it gets into the woodwork, under the lights, cracks and joints, in the rafters, even in the brickwork; consequently, if all the plants in a house were thoroughly cleaned or destroyed, it would be sure to make its appearance on any fresh ones that may be introduced into a house that was infested with the insect. It will also live upon almost any description of plant grown in heat in the summer season, or, even in winter where much heat is used; it increases very fast. There is one circumstance that slightly mitigates its objectionable presence; that is, the plants it feeds upon are not injured thereby to so great an extent as they are by some insects, but, if left unmolested, it increases to such an extent as to virtually smother the plants; its excrement coating over the surface of the leaves, clogging up the pores as completely, almost, as if they had received a coat of varnish.

On Vines.

On Vines it is an intolerable pest, requiring more labour to keep it under than the crop is worth. The bunches get almost as bad as if they had been smeared with treacle, and, whatever care is employed in keeping it down, the bloom and general appearance is destroyed. Where Vines are affected, as soon as the leaves are off, prune, and take them down; scrub and paint every portion of wood and iron, point and whitewash the brickwork. All the loose old bark must be removed, getting well into every crevice about the spurs. To a gallon of water add as much clay as will bring it to the consistency of paint, to which add 1 lb. of flowers of sulphur, and 4 oz. of Gishurst; stir all well together, and paint the canes all over twice, getting the mixture into every crack or interstice in the bark. This must be completed before there is any indication of the buds pushing, or they will be injured; and, if the dressing is well done, no bugs will appear the following season. In the Fig-house they are more difficult to deal with, as the young fruit are liable to drop off through the application of any dressing that will kill the insects; yet there are not so many hiding places on the bark of Figs as upon Vines. As soon as the leaves are off, give three dressings with Abyssinian mixture, using it at 4 oz. to the gallon. If this is carefully applied it will effectually destroy the bugs. The house must undergo a similar cleansing to that recommended for Vineries. Pines that are affected with mealy bug are not worth the labour of cleaning; and the best course to follow is to destroy them, thoroughly cleansing the house, and commencing afresh with a clean stock. Upon Cucumbers and Melons this insect thrives apace, and the plants will not stand any dressing sufficiently strong to kill them. It sometimes happens that plants affected cannot for a time be spared; then it becomes necessary to keep the insects as well under as possible with the sponge and syringe, using clean tepid water; but, wherever the plants can be done without, the best plan is to destroy them, giving the house a thorough cleaning before starting a fresh lot. Mealy bug is, by far, the most difficult insect to thoroughly eradicate where once it gets established; and, as I have already said, there is no possibility of its complete destruction, except persistent action until every trace of it disappears. In many places, in the winter season, its numbers are reduced so that very few can be found; but sufficient escape to furnish a breeding stock in the spring, when it begins to increase, and in a few weeks it is as plentiful as ever, entailing a repetition of all the work; whereas, if a little more perseverance had been employed, its destruction would have been complete; and

nothing less than this should be deemed sufficient. More especially as there is this incentive, that it is not, like such insects as thrips, red spider, or aphides, that are sure to make their appearance yearly; for, if once it is completely destroyed, there is no fear of its re-appearance unless it is brought in on some infected plant.

Remedies for Mealy Bug.

Where the plants in a house are infested with mealy bug, nothing but perseverance will effect its thorough destruction. No one or two dressings, however carefully applied, will reach all the insects or their eggs. Spirits of wine, turpentine, and several preparations sold for its destruction, have been recommended, applying them with a small camel's-hair brush to the axils of the leaves and other affected parts. Where only a single small plant or two are affected, these may answer; but, where it has spread over any considerable number, it takes more time than the plants would be worth. Any little plants that I get which are affected with the insect have to undergo a rigid quarantine, by placing them at one corner of a house away from everything else, until I am sure they are quite clean. When all or any considerable number of the occupants of a house are affected, the only way is to commence at one end, dipping the small stock, and thoroughly washing with the syringe every part of the larger plants, from their junction with the soil upwards. "Abyssinian Mixture," or Fowler's "Insecticide," 4 oz., or 5 oz. to the gallon, are the only preparations I have found effectual for the thorough destruction of this insect, without injuring some or other of the plants. Every plant, as it is washed, should be removed to another house until the whole are gone through. Clear out all tan, or similar plunging material; scrub all the woodwork with water, soap, and brush; stop up all cracks or open joints; give two coats of paint, getting well to the under-side of all slide-lights and ventilators; point all brickwork, especially under the wall-plates, and finish by two good coats of white-wash. Where the insect has been allowed to get to such a head as I have sometimes seen it, there is no certainty of effectually destroying it without the work is so completed as not to leave a single place such as described where it can lodge. When the house is fit for the plants, return them, and in ten days from the time of their first washing give them another dressing, going thoroughly over them as in the first. This should be repeated in all four times. Do not omit a single plant, no matter whether any insects can be found upon it or no; for there possibly may be a nest of eggs in some cracks in the bark undetectable, and, if such were the case, all the work would go for nothing. I once had this insect in five of the houses, upon everything that it would live upon, more or less, Vines included; the labour in keeping it down by the use of sponge and brush was such that I found it impossible to go on as we were, so I came to the conclusion that there was no resource but trying to destroy it altogether. We began about the end of September, when the plants were just maturing their growth and the insect not breeding so fast. Washing the plants took two men six weeks, and it was about the best spent labour I ever employed. Twice since I have caught the insect at exhibitions, from the plants coming in contact with others badly affected with it (plants in such condition should not be admitted to any exhibition), and the insect had spread over a considerable number of the occupants of a house before it was observed; three or four dressings, such as above described, effectually cleared them. It had not got possession of either wood or brickwork. Orchids, from the repeated sponging they undergo for other insects, do not often suffer much from this, except plants with ample foliage, such as *Sobralias*, *Phajus*, or *Peristerias*; with these, perseverance in use of sponge and brush is all the remedy that can be safely employed. The insect will live upon Ferns; yet, here it does not increase so fast, but the plants will not stand any dressing strong enough to kill it. Copious syringing during the growing season, and extra washings with clean water, laying the plants down on their sides, are all that can be done. In large houses, such as are devoted to Palms, they spread rapidly, and there is little chance of completely clearing them; these plants will bear large quantities of water overhead, by which means they may be kept from getting to an unmanageable head. Where conservatory climbers are infested with the bug, it is useless

to clean the general occupants of the house unless the climbers are thoroughly cleansed. When at rest they must be cut back into the hard wood, take them off the wires, and immerse them overhead for two hours in Abyssinian mixture, 8 oz. to the gallon.

T. BAINES.

THE BLACKBIRD.

I HAVE to thank your correspondent "R." (see p. 110) for drawing my attention to Tennyson's verses condemning the destruction of blackbirds for their fruit-eating propensities. Probably the poet's squares of fruit-trees are only of limited extent, and, if he lost all his fruit by the aid of his feathered friends he would possibly not feel the loss very much. With gardeners, however, the case is different, and reason has to be preferred to rhyme in their dealing with blackbirds when too numerous, so as to preserve their fruit from their ravages. It all comes to this, that some birds must be kept under when too destructive, and others protected when they are found to be insect or wild-seed eaters. I hope "R." will pardon me for my presumption in composing and inscribing the following verses to him on the blackbird:—

O! blackbird! though you whistle well,
We gardeners grudge to pay its price,
By your raids on our fruits so nice,
In number more than tongue can tell.
We're charmed to hear you in the spring,
Perch'd on some Oak, or tall Ash tree,
Pealing your notes with thrilling glee,—
To us as a peace-offering.
But when each Rasp' or Gooseberry-bush
In fruit, shows forth a ripening tint,
Then you black minstrels take the hint,
And from the "Woodlands" make a rush.
The espaliers, and the standards, all
Are rifled of their choicest fruits.
Even those on trees, with straggling shoots
Are not safe on the netted wall.
Your golden bills flash in our sight,
And give, when flush'd, an angry sound,
As much as tell us that the ground,
And plots of fruits are yours by right.
Take warning! for the steel rat-traps
Will thin your numbers day by day,
Despite what all the poets say,
And other sentimental chaps.

WILLIAM TILLERY.

Welbeck Gardens.

Ants.—Of recipes that have been published for the destruction of ants, I have found boiling water to be the most effectual, but it cannot always be applied, for not unfrequently their nests occur amongst the crocks in Orchid pots. On Saturday last I had occasion to get a square of glass put in an inside door of one of our Orchid houses, and in less than two hours I noticed that the new putty was literally brown with ants, I therefore put five or six lumps of putty in different parts of the house, and they were immediately covered with these little pests. My plan is to have a piece of putty about the size of a teacup, in a rather soft state, then to go to the lumps previously laid down and to dab it on them, a plan by which thousands may be trapped in a few minutes. Then mix the ants up in the putty, and it is ready to lay down again.—E. WHITEHEAD, *Blackburn*.

THE AMERICAN ALOE.

THE American Aloe first flowered in Britain in 1774, in the gardens of Cliff House, Salcombe, South Devon, and was considered one of the greatest horticultural curiosities of the age, people being admitted to see it by ticket, and the popular belief of the day was, and, amongst many, still is, that the Aloe only blossoms when the plant is 100 years old, and then die. Almost every year Aloes bloom in the gardens around this neighbourhood, but are seldom of such magnitude and symmetry as is represented in the annexed illustration. This magnificent plant is forty-five years of age, and has been all that time on a terrace close to the sea in Lord Kingsale's beautiful seat, Ringrone, Salcombe, Kingsbridge, South Devon. The plant first showed signs of blooming in the middle of May last, and was in full flower in the middle of October, when the photograph was taken from which our engraving has been made. The flower-stem grew at first from 3 to 4 inches a day, but the rate of growth gradually became less and less as the

blossoms were developed; the number of flowering-branches is 40, and the average number of blossoms on each branch 152, making a total of about 6,000. The plant is 25 feet 6 inches high, and the average length of the leaves is 6 feet; they are armed with dangerous hooks on the sides, and a long sharp

native of Southern America what the Date Palm is to the African, or the Rice plant to the Chinese and Hindoos. From the juice they make a luscious wine called pulqué; from the leaves they extract a beautiful silk-like fibre of great length, from which they weave various articles for clothing; of the dry

An American Aloe in bloom at Lord Kingsale's, in Devon.

spike at the end, so hard that the natives of South America use them as nails. The circumference of the body of the plant is 36 feet, that of the stem 13 inches. The fact of these tropical plants growing in Devon is enough to show how very mild the climate of that county is. These Aloes are to the

stems they make the framework of their huts, which are covered and surrounded with the leaves; and the plant itself is placed thickly together round the garden or fold, to form a hedge, its very defensive armour keeping out all comers; and, when dead and dry, all parts of the plant supply fuel. LAMBTON YOUNG.

THE KITCHEN GARDEN.

THE POTATO DISEASE AND ITS PREVENTION.

By WM. TILLERY, Welbeck.

It is said that the Potato disease was prevalent both amongst the wild and cultivated varieties in South America long before it reached our shores; and, in Germany, Von Martius has described it under the name of the "moist gangrene," and as having done great injury to the crops there from 1830 to 1841. In the United States of North America, and in Canada, it was likewise detected a few years before 1845, the year when it first appeared most virulently on the continent, and in the British Islands a month or two later. A microscopic Fungus or mildew, now named *Peronospora infestans*, is known as the minute parasite attendant on the disease, but, whether it produces it, or only appears as an attendant after the mischief begins, remains yet to be discovered. From the experiments of De Bary, it is stated that he has produced the disease by placing the spores of the Fungus on the leaves of healthy-growing Potatoes; and, if this is found to be correct by other experimentalists, there can be no doubt as to the cause. At the present time, however, we only know that it generally appears in wet summers, about the middle of July, all through August, and in the beginning of September; and that, in a certain stage of the Potato's growth—namely, about the ripening period—any experienced grower of Potatoes, who has studied the disease for any length of time, can tell to a few days when his crops will be stricken by it. This always occurs in very wet weather with a high temperature; and, if thunder-storms prevail during the time, with the atmosphere close and sultry, the black specks on the leaves and haulm will spread more rapidly, but that electricity is the principle cause of it, it is, I think, "not yet proven."

Rest Fungus Spores.

Some experiments were made in 1846 by me in fumigating the sound and diseased Potatoes, on purpose to destroy the rest-spores of the Fungus; the results, however, were not encouraging. A large close Mushroom-house in the garden was fitted up with shallow shelves, and the apparently sound and diseased tubers were placed on them in thin layers. The fumigation of them was done with chlorine gas and sulphur, in the following way, namely, 2 lbs. of the black oxide of manganese and 4 lbs. of common salt were mixed together, and put into saucers, and 8 lbs. of sulphuric acid poured over the mixture to evolve the gas, which was kept close in the house for a few days. Afterwards, 3 lbs. of flowers of sulphur was ignited, and the fumes of it kept close in the house for three hours, making a sufficiently strong dose to destroy the spores of any Fungus it could reach. All the tubers which had been fumigated, and were fit for planting in the spring of 1847 were planted in a field of fresh soil prepared on purpose for them, but, at lifting time, the crop was found as diseased as the others not operated upon in another field. The cost of preparing the chlorine gas and sulphur was as follows, namely:—2 lbs. of black oxide of manganese, at 4d. per lb., 8d.; 8 lbs. of sulphuric acid, at 4d. per lb., 2s. 8d.; 3 lbs. of sulphur, at 4d. per lb., 1s.; 4 lbs. of common salt, at 1d. per lb., 4d.—total, 4s. 8d. A new parasitic mildew, the *Oidium Tuckeri*, has of late years attacked the cultivated Grape Vine, but gardeners can now conquer it by dusting flowers of sulphur on the foliage and young bunches of the Grapes when it first appears on them, and by paying proper attention to the ventilation of their Vineries. With the Potato plant, however, it is quite different, for if the rest-spores of the Fungus are deposited in the inside cells of the tubers, no dusting, dipping, or fumigation will reach to destroy them. In 1848 when the late Lord Howard De Walden was our ambassador at Lisbon, he sent from Portugal three tons of a red Kidney Potato, a variety which was warranted never to have had the disease there. They were all kept for setting, and planted in the spring of 1849 in a field of newly broken up light forest soil. In the same field were planted some of a strong-growing kind, named the Farmer's Profits, and at lifting time they showed less of the disease than the Portuguese variety. Now, if these red Kidneys never had the disease in Portugal, there could have been no rest-spores in the tubers, nor in the soil, for the field had never grown Potatoes before. To show that the infection did not proceed from being planted in the same field with the other variety, some of the Portuguese Potatoes were planted in a plot by themselves, and not near any other sort, and they proved quite as diseased as the others at raising time. Under shelter of a glass-covered wall here of great length, and used principally for growing orchard-house fruit trees, some experiments have been tried by me in growing Potatoes of both early and late varieties, to see if the disease would appear on them when grown under glass. In 1872, when the trials first commenced, no disease appeared on any of the early kinds grown in pots, and which ripened in May and June, but in the end of July a row of

Rivers's Ashleaf planted out in the border showed slightly some specks of the mildew on the leaves, but when the tubers were lifted, they were not in the least infected with it. Some Tomatoes fruiting at the same time in this erection were likewise attacked in the fruit with the black specks of the disease, but not on the foliage. A row of Dalmahoy Regents was planted late in May in the border of the same house to see if the disease would appear on them in September or October, but they were lifted quite sound in November. This year, in the same structure, some more experiments were tried by me in growing both very early and late Potatoes in a very moist state by frequently syringing them, as well as watering their roots with liquid manure made from horse-droppings, and full of ammonia. The earliest kinds were planted in the border in the beginning of February, and were frequently syringed on the tops and watered at the roots with this liquid manure to see if the disease would appear on them at the ripening period in May. I suppose, however, that the temperature was not high enough for its development, for they kept all quite sound till lifted. Another row was planted in April to ripen about the period of the earliest planted in the open air in July, and a still later row to ripen in August and September. They were all grown in the very rich soil of the border, and kept well watered with the liquid manure at times, but no rain ever reached them all the time of their growth, and on lifting them no diseased tubes were found in any of the rows.

Dry Seasons v. the Disease.

From the above experiments it would seem that if we could keep our Potato crops free from rain in very wet summers, and from other atmospheric influences during their ripening period, they would be safe from the disease. As this, however, cannot be done, the next palliative is to plant them in the driest and best soils, and to give them more space in the rows for the circulation of the air to keep the haulm and foliage drier in wet weather. That the influence of wet and dry summers has a great effect on the Potato disease is now sufficiently known to all growers of them. In 1845, the year in which the disease first appeared in the British islands to any extent, the months of June, July, and August were excessively wet, the rainfall here being nearly 12½ inches. In August alone the rainfall was 6½ inches, with a high temperature at times during the month, and, had the peculiar signs of the disease been known then as now, there is no doubt but that it would have been detected sooner than it was. By the end of September the crops in the fields were all dead on the tops, and on taking up here the produce of a field of nine acres on 9th of October the tubers were found to be quite one-half diseased. In 1846, the year of the Potato famine in Ireland, the month of August was again very wet, 4½ inches of rain having fallen here during its course, with frequent thunder-storms, and the temperature high when they occurred. The disease again appeared virulently by the end of August and beginning of September, and there was a great loss in the crops at lifting time. In 1848 there was a rainfall here of 35 inches (the average annual rainfall being about 25 inches), the months of August, September, and October being very wet. In August there were twenty-one rainy days, and from the 21st till the end of the month frequent thunder-storms occurring, with an accompanying high temperature. In the beginning of September the disease appeared in its worst form amongst the late varieties of Potatoes in the fields. In 1852, another very wet year was registered here, but the rainfalls in July and August were much below the average, and the mean temperature being rather low, the disease was not so general nor so virulent as in other wet years. In October, November, and December, however, the rainfall was excessive here, nearly 12 inches having fallen, and the usual quantity of winter Wheat could not be sown on strong soils. The result was, therefore, a most deficient Wheat crop in 1853. In 1860, when the next very wet summer occurred, the rainfall here, in July, August, and September, was above 11 inches, of which more than 5 inches fell in August. The temperature, however, in these months was much below the average, with no thunder-storms or sultry weather, and the disease was, therefore, not so general as usual in wet years. In 1861 and 1862 the disease was again very general and bad, and in the very wet autumn of 1867 there was a great loss sustained by all growers, from its attacking their field Potatoes later than usual, and from supertuberation from a second growth. Perhaps the disease was never more general and virulent than in 1872, for it appeared early in July amongst the early kinds of Potatoes, and all the late crops were hopelessly stricken by it before the middle of August. From the 9th until the 14th of July there were thunder-storms with heavy rain every day, with the temperature nearly tropical, and, therefore, suitable for the development of the disease amongst the unlifted early and second early crops, and they were found a mass of rotteness when raised. The rainfall here in 1872 was 38 inches 25 being the largest quantity I have ever registered in the thirty-six

years of my keeping the register. In the present year the rainfall has been below the average, January and August being the rainiest months. In the spring both the early and late varieties of Potatoes were planted under favourable circumstances as regards the weather, and I never recollect in any year seeing better and sounder crops of the early kinds lifted. At all the local vegetable shows in this district it was remarked by the judges, that better samples never came before them, being very large, clear in the skins, and disease of tubers at a minimum. In the latter portion of July and the first half of August the weather was very dry and warm, and suitable for ripening all the early and second early kinds, and all intended for seed were stored free from disease. In the last portion of August, however, a succession of rainy days, with thunder-storms, occurred, and the disease attacked the late crops on wet soils and in low situations, but it is to be hoped that the loss will not be so great as in 1872 as the general crop is so good.

Early and second-early varieties best.

In the intervening years between the above-stated wet ones, the disease did little injury to the general crops of Potatoes, and in the particularly dry and warm summers and autumns of 1868 and 1870, it was only seen in a few damp and low localities; but it is particularly worthy of notice that it has appeared more or less every year since 1845. There is not the least doubt but that some of our best keeping early and second early varieties of Potatoes can be thoroughly ripened in July, before the disease can attack them so as to cause much loss in the crops. This I have proved since 1846, by growing large quantities for consumption and for keeping; and in letters that year to the leading journals and the *Economist*, I promulgated this practice as the safest way of growing our Potato crops for the future. It is said by many growers that the early-ripened sorts will not keep good or long enough to supply the markets with the mealy and good flavoured varieties of the Lapstone and Regent sections. This may not be the case at present, but new seedlings of first-rate properties as to keeping qualities, flavour, and early ripening, will soon be selected by nurserymen and other growers to sell to their customers. The following is a list of early and second early varieties of the Kidney kind, which I have proved to be excellent croppers and keepers, namely:—Mona's Pride, Myatt's Prolific, Veitch's and Rivers's Ashleaf, and a new sort, sent out by the Messrs. Lee, of Hammersmith, under the name of the Hammer-smith Early Kidney. Of the round or pebble-shaped section of the early and second early kinds, the best I have tried are the following:—Coldstream Early, Harbinger, The Clipper, and Champion (all three seedlings of Bell & Thorpe's); Styffe Castle Seedling, Headley's Early Nonpareil, Burfitt's Seedling, Daintree's Early, and Yorkshire Hero. Some other seedlings, raised by Messrs. Fenn and Dean, have been certificated by the Royal Horticultural Society, and they will doubtless meet the demand for good early keeping kinds when they send them out for sale. The American new sorts of Potato, which have lately been introduced into this country, are a very distinct race in their foliage and dwarf habit, and some of them are very early ripeners, such as the Early Rose, Prolific, and King of the Earlies. They are all good croppers, but some of them have a peculiar earthy flavour when grown on strong soils, and they are all as much subject to the disease as our own varieties in wet seasons. They evidently do best in warm dry summers, for this year, with me, Climax, Peerless, and Prolific have been excellent in flavour and very productive, and free from the disease. They will, doubtless, be very useful for crossing with some of our best sorts for raising seedlings of a dwarf habit and early ripening properties. All our best-flavoured mealy sorts are very subject to the disease, such as the Flukes, Lapstones, and Regents, and seedlings crossed between them and the American varieties might have a better constitution. I have no great faith in resorting to any of the wild varieties of Potatoes of South America for raising seedlings from, for in 1848 I raised some plants from Peruvian seeds, and when their tubers got large enough for use, I found them of bad flavour, and the disease attacked them in the same way as our native sorts. They were something like in the foliage, and had the dull red skins and white flowers of the American varieties lately sent out. Although no kind of Potatoes may be said to be quite free from the disease in bad seasons, yet some are so little affected by it that a sound crop may always be reckoned on, and they all belong to the very late ripening varieties, with red leathery skins, and strong woody haulm. Last year, when the disease was so prevalent, I grew here good crops of the Red-skinned Flour-ball, Wood's Scarlet Prolific, and Millett's Manifold, and the stems kept green and growing till cut down by the frost. The qualities of these varieties, however, are not very good as regards flavour, being better roasted than boiled, but they keep well in the spring without sprouting, and are well adapted for feeding pigs or cattle, which is a recommendation.

Desirability of raising Seedlings.

Before the Potato disease appeared in this country, some favourite old varieties, which had been some years in cultivation, gradually wore out and disappeared, and new seedlings took their places. Some forty years ago I can remember, for field cultivation, the red and white Dons and the Perthshire Rough Reds, so much run upon in the London markets, the Breadfruits likewise (the progenitors of the Regent section), and Taylor's Fortyfold, were favourite kinds; but they have all now nearly disappeared from the nurserymen's lists. In some seasons, then, there was a disease named the dry rot, or gangrene, which attacked the tubers, but it did not affect the general crop, nor cause any great alarm amongst growers of Potatoes when it did appear. At that time some of the varieties grew such immense crops of seed-plums, that cartloads could have been gathered in the fields at lifting time; but we seldom now see any of the kinds seed so freely as they did then, unless in exceptionally warm summers. The Potato plant being an exotic, there is no doubt but that our changeable and wet climate has an effect on its constitution, and makes the raising of seedling varieties a necessity, as they seldom continue longer in cultivation than from ten to twelve years. Some of our best kinds, such as the Lapstones, Flukes, Regents, and the second-early Kidneys, reproduce seedlings of the same type, so that there is no fear of any degeneration in them. A few years ago, the late Mr. Paterson, of Dundee, raised some seedling varieties of great merit, and which are still cultivated in quantities for the market; but they will gradually have to succumb to newer and better sorts.

Storing Seed Potatoes.

The keeping and preparing Potatoes for setting is a great point, and the best results have been recorded of early kinds, where the tubers have been "greened" in the open air before being stored for the winter. If they are packed in shallow boxes, with the eye-ends upwards, a great quantity can be put together in a small space; and, being allowed to sprout slowly by keeping them in cool places safe from frost, the shoots become stiff and hardy at planting-out time. No hurry is then required in the spring months for planting them out, until the weather and soil are favourable for that operation. These hardy-sprouted tubers, when set whole, and their shoots appear above ground, will withstand the spring frosts better, and come in earlier, than those planted in the autumn or in the early spring months. Of course it is not possible for extensive growers of late varieties to adopt this plan; but their Potatoes intended for setting might be placed thinly on the floors of outbuildings or sheds, and frequently turned to keep them from sprouting too much. Temporary sheds might likewise be erected for this purpose, the walls being made with thick sods, and lined with dry Fern or straw, and the roof thatched with any waste materials to keep out the rain and frost. Doors should be made at each end, to be opened for ventilation in mild weather, to prevent the tubers from sprouting too much.

Planting and Manuring.

Some recommend autumn planting, and it may answer in light soils, if the precaution is taken to plant the sets deeper than they usually are, so as to be out of the reach of severe frosts. On strong undrained soils, however, I have often seen the sets rot in the ground, from grubs eating into them, and the crop suffered in consequence. Autumn-planted Potatoes, therefore, run more risks than the spring-planted, and they do not, as a rule, come in any earlier; so that the advantage of the system is not greater for warding off the disease. Very late planting in the spring is another panacea recommended by some enthusiastic growers of Potatoes, who say that, if they are not ripe enough in August and September, the disease will not attack them to cause any loss in the crop. Last year I planted some rows of Myatt's Prolific in the middle of June on purpose to see if they would escape; but, on lifting them in October, they showed more diseased tubers than any I have yet raised. Some more rows of late varieties were planted at the same time as the Prolifics, and were showing sturdy growth until the frosts, on the mornings of the 29th and 30th of September, blackened all their tops, and the tubers were so small that they were not worth the lifting. That the manures used for growing Potatoes have a great influence on the disease is now well known to all cultivators of them. For the late crops, perhaps, stable or farm-yard manure, if well decomposed when used, is as safe as any. When ten tons of this manure is applied per acre at planting-time to land in good condition, and a top-dressing of 3 cwts. of best guano mixed with the same quantity of wood or coal-ashes, put on in showery weather in April, it will make an excellent stimulant for forcing on the crop. The cost per acre for this manure will be about £4 13s., viz.: 10 tons best decomposed farm manure, at 6s. per ton, £3; 3 cwt. best guano, at 11s. per cwt., £1 13s.—total, £4 13s. Another good manure for strong soils, if they are rich in organic matter, is about

30 bushels of soot, and 12 cwt. of salt mixed together, and put into the drills at planting time; this quantity will do for an acre, and the cost will be about, for 30 bushels of soot, at 7d. per bushel, 17s. 6d. for 12 cwt. of salt, at 1s. 6d. per cwt., 18s.—total, £1 15s. 6d. Guano, if of the best quality, is highly stimulating, and, when used in the drills, should be mixed with wood, peat, or coal-ashes, at the rate of 4 cwt. of guano and 2 tons of ashes to manure an acre, at the cost of £3 4s., viz.: 4 cwt. best guano, at 11s. per cwt., £2 4s.; 2 tons best charcoal-dust or peat, at 10s. per ton, £1—total, £3 4s. If coal-ashes are used the manure will be cheaper. For light sandy soils salt is an excellent fertiliser, and it likewise forms a crust on the surface of the drills and keeps the high winds from levelling them. If used in the drills at the rate of 20 cwt. of salt and 12 bushels of soot per acre the cost will be about £1 17s., viz.: 20 cwt. of salt at 1s. 6d. per cwt., £1 10s.; 12 bushels of soot, at 7d. per bushel, 7s.—total, £1 17s. I have used the sulphates of soda and magnesia mixed with the nitrate of potash as a top-dressing in the following proportions, and at the cost of about £2 9s. 6d. per acre, viz.: 1 cwt. of the sulphate of soda, at 18s. per cwt., 18s.; 1 cwt. of the sulphate of magnesia, at 18s. per cwt., 18s.; $\frac{1}{2}$ cwt. of the nitrate of potash, at £1 7s. 0d. per cwt., 13s. 6d.—total, £2 9s. 6d.* When this mixture was put on the drills in showery weather in April or May it promoted the growth of an excellent crop of Potatoes, quite free from the disease, on very rich soil that formerly produced a very diseased crop. In growing the early and second early varieties in gardens or fields where the soil has frequently been heavily manured, and, therefore, still retains quantities of organic matter, simple manures such as charred rubbish, decayed tan, or sawdust, will grow good crops of Potatoes at little expense and free from the disease. I always, however, find that whenever coal-ashes is used by itself or mixed, it has a great tendency to make the tubers have rough scabby skins, it ought, therefore, not to be used unless in small quantities. A new manure, under the name of Phospho-Silicon, has lately been introduced by the Rev. H. Moule, and is said by him to be effectual in curing the disease. It will, no doubt, be extensively used this year in experiments by growers of Potatoes, and duly reported on by them. In years when the Potato crops show much of the disease great care must be taken in picking out the diseased tubers, and only storing those which are sound or least infected by it. This can be done best by placing them on the floors of sheds or outbuildings, where they can be frequently examined and picked over, and afterwards covered with litter to keep them from the air and frosts till stored. Where a great quantity has to be stored this can only be managed by pitting them in ridges in the open air. When this is done, I have found layers of quicklime or charcoal-dust and sifted coal-ashes, when put into the ridges amongst the tubers, to be effectual in keeping them sound. The diseased tubers do not infect the sound ones, but they rot and bring dampness and heating into the pits which the lime and charcoal dust dries up. The ridges must not be more than 3 or 4 feet wide at the base; nor more than about 3 feet 6 inches high, in order that heating may not be generated in them, should the tubers be put in damp at storing time. It is a bad practice to put too much straw on the top of the tubers in the ridges when earthing them up, as it rots and gives them a bad flavour.

Our future Potato crops.

As to the future of our Potato crops and the wearing-out theory, the question has often been mooted, whether we should not give over cultivating the noble tuber to the extent hitherto done, and find other substitutes for it. There is, however, no more reason in giving over growing the Potato plant than in not growing the cereals or any other crop of our food crops, for they are all subject to failures in bad seasons. After such a season of disease amongst Potatoes as we had last year, the same land has been planted again this year with sets taken, in many instances, from diseased tubers, and the result is one of the best crops ever lifted of the early and second early kinds. Unfortunately, owing to the wet weather prevailing in the latter portion of August, the late planted varieties have been infected by the disease in low situations, but the crops of them being good the loss will not be seriously felt as in some years. That the plant is wearing out from being more diseased than formerly, or from the exhaustion of the soil affecting its vitality, is not warranted by experience, for I have known gardens where it has been grown every year on the same plot, or border, for more than a quarter of a century, and yet produced good crops in favourable seasons. This, however, would not be good practice for extensive growers to follow, such as farmers, with plenty of land for a rotation of crops, and who could find fresh soil to plant their Potatoes in every year. Sub-soil-ploughing strong undrained soils, or digging

them deep, would be another help to ward off the disease, for it relieves such soils of their super-abundant moisture. Giving more space in the rows than what is usually done, or growing such low plants as Carrots or Kohl Rabbi, in alternate rows, between the Potatoes, would lessen the danger from the disease. Cottagers should only plant the early and second early kinds of Potatoes in their garden ground, leaving as much room between each row as to be able to plant in May and June Savoys, Broccoli, Brussels Sprouts, and Scotch-kale, the best and most profitable of all hardy vegetables for standing the severe frosts in winter. The Potatoes will gradually be lifted for use, and the last lot will be ripe enough to save for seed by the middle of July, when the vegetables can be all earthed up. There is a great risk in cottagers planting the late sorts of Potatoes in the rich soil of their gardens, for they are in general shaded much with fruit-trees, and in wet summers the disease runs riot, and destroys all their crops. The farmers in the neighbourhood are often willing to let cottagers and others plant a few rows of late Potatoes on their fallows for the sake of the manure they put on the land. This manure is generally made from horse-droppings and road-scrappings, mixed with house-ashes, and raises excellent crops of Wheat the year after. Owing to the present favourable season, and the good crops of early planted Potatoes, the outcry about the disease will subside for a time, as it has done in former years. Another wet summer, however, will again show it as virulent as ever, and we ought to be prepared to make the loss as little felt as possible. As I have before stated, this I am convinced can best be done by planting for the main crops, as early as the season will permit, the earliest-ripening varieties of good keeping kinds. Every year's experience, since 1845, whether the summers have been wet or dry, has only confirmed this practice in my case, and I believe many growers are now of opinion that the system is the safest. Should men of science and practice conjointly discover that the parasitic Fungus *Peronospora infestans* is the cause of the disease, then it will have to be found out how the rest-spores of the Fungus are preserved for continuing the life of the species in a new season. We may then be able to find a cure for it by steeping or dressing the sets intended for planting, or if in the soil, use manures likely to destroy its development. If the conditions, however, out of which it originates are atmospheric, of which there can be little doubt, we will then have to depend upon the seasons for the only cure.

Lord Cathcart's Prize.

In the competition for Lord Cathcart's prize on the Potato disease, none of the essayists were successful, and the judges' report says, "As regards the botanical part of the subject, it must be confessed that all the essayists appear to be in the arrear of the present state of scientific knowledge." From this it appears that none of the essayists were regarded by the judges as good botanists; but that botany will have much to do with the discovery of the cause of the disease is doubtful, and the present state of scientific knowledge has added as yet very little to our knowledge concerning it. The judges, however, recommend the council to apply the £100 prize to some competent mycologist, so as to induce him to undertake the life-history of the Potato Fungus, and if this is done, it is not likely to lead to any great result. The life histories of the mildews which attack the Pea and the Turnip crops in dry warm autumns, and the Vine in spring and summer, must be known to mycologists before this, but no applied cure prevents these mildews from regularly appearing in years when the weather is favourable for their development. Another recommendation of the judges to the council is to award valuable prizes for the best disease-proof early and late Potatoes. These prizes are not to be awarded till after a three years' trial of their resistance to the disease, and besides, they must have good cropping, keeping, and cooking qualities. From a quarter of a century's experience with early and second early varieties, I have found that none of them are disease-proof, being only so when ripened in July and beginning of August before the disease appears. As to the late sorts, it is only a few that have thick leathery red skins and strong woody haulm which resist the disease, and I believe as much is known about them already as will transpire after the three years' trial. New seedling varieties, however, of this section, with better cooking qualities, would be worthy of prizes.

Change of Seed.

The changing of Potatoes, for setting, from one description of soil to another has a marked effect on their cropping and other qualities. I have found that a good change is made by setting those grown on a peat or boggy soil on light sandy ones, and *vice versa*; and likewise in setting those grown on light soils on strong loamy ones. This year I planted a quantity of a red mealy variety, free from disease, and grown in Prussia. The crop turned out excellent, and when lifted in September, not a diseased tuber was found among them.

* The cost of these chemical manures will be less if purchased in larger quantities.

THE ARBORETUM.

HARDY TREES AND SHRUBS.

By GEORGE GORDON, A.L.S.

THE SYCAMORE, OR FALSE PLANE (*ACER PSEUDO-PLATANUS*).

THIS forms a large tree 60 feet high, usually clear of branches for a considerable height. It is common all over Europe, particularly in Switzerland, Germany, Austria, and Italy, and is well suited for planting near the seashore for shelter, as it grows quickly, and resists the spray better than most other trees. The leaves are large, smooth, and cordate at the base, with five acuminate unequally-toothed lobes, and long foot-stalks. The flowers are yellowish-green, and produced in long, dense, drooping catkin-like racemes in May and June. The keys or fruit are smooth, with rather spreading and ample wings. There are several varieties of the common Sycamore, of which the following are the most striking and distinct:—

1. THE PURPLE-LEAVED SYCAMORE (*Acer Pseudo-Platanus purpureum*).—The leaves of this variety are of a beautiful violet-purple on the under-side, and in summer and autumn, when they are slightly ruffled by the wind, give the tree the appearance of being alternately clothed in purple and pale green. It originated in the nursery of Mr. Saunders, of Jersey, in 1828.

2. THE WHITE VARIEGATED-LEAVED SYCAMORE (*Acer Pseudo-Platanus albo variegatum*).—The leaves of this variety are finely blotched and striped with white. It is the oldest and most common of the variegated Sycamores, and, although a handsome variety, is inferior to either of the following.

3. THE YELLOW VARIEGATED-LEAVED SYCAMORE OR CORSTORPHINE PLANE (*Acer Pseudo-Platanus flavo variegatum*).—This is a handsome variety, of Scotch origin, the leaves of which are amply blotched and striped with yellow, particularly in the case of full-grown trees.

4. THE NEW BELGIAN VARIEGATED SYCAMORE (*Acer Pseudo-Platanus Leopoldi*).—The leaves of this variety are almost wholly of a pale yellow colour, frequently more or less tinted with red, and, owing to their having, but very little green colour in them, they appear, at a short distance, about as ornamental as flowers. It is of Belgian origin, and is decidedly the most beautiful of all the variegated varieties of *Acer* in cultivation.

5. THE LONG-LEAVED SYCAMORE (*Acer Pseudo-Platanus longifolium*).—The leaves of this variety are deeply and acutely lobed, and are set on very long foot-stalks. It originated in the nursery of Messrs. Booth, of Hamburgh, and forms a very striking variety.

The Golden Osier or Willow.—The Golden-branched Willow (*Salix vitellina*) is a low deciduous tree, and its long taper-shoots are especially useful to gardeners for many purposes, especially for tying wall trees, espaliers, Raspberries, or, in fact, anything that requires a strong ligature. Although Willows of all kinds grow more luxuriantly in damp situations, such as the margins of ponds or streams, still I have frequently planted them in poor sandy soil, and they will, in fact, grow in any soil or situation in sufficient quantities for the gardener; and I should recommend every gardener to procure a few cuttings of the Golden variety, and plant in any corner where there is room, so as to secure a few bundles of pliable twigs

for tying purposes. In addition to its utility as stated above, the Yellow Willow has a very ornamental appearance when planted in groups in large shrubberies. Their masses of waving golden branches in winter, when the leaves are off, have a pretty appearance in the rear of masses of evergreens, especially when associated with masses of the Red Dog-wood (*Cornus sanguinea*), another low-growing deciduous shrub that might be advantageously used for giving life and colour to masses of dark-leaved shrubs in winter, in ornamental game coverts or large shrubberies. Referring again to the Golden Willow, after all the pliable twigs that are required for use have been taken off, the remainder, in the spring, just before growth commences, should be cut well back. This keeps them dwarf, and stimulates the further production of plenty of young clean shoots. Cuttings of strong shoots, about 15 inches long, planted firmly in the ground, about two-thirds of their length, will soon make good plants.—E. H.

Tan for Hedge-growing.—Whoever has travelled on the high road to Eutin—a road which passes through some of the most charming scenery in East Holstein—cannot fail to have been struck by the excellence of the hedges right and left. They were grown, many of them, according to the plan recommended by Mr. Bruhns (an inspector of highways), the peculiarity of his mode of culture being the employment of tan; i.e., tanner's spent bark. His usual method of proceeding is as follows:

He raises a bank of earth a little over 12 inches in height by 24 inches in width, and plants the young Thorns on the same at intervals of 12 inches. The variety selected for the purpose is *Crataegus monogyna*, the one-styled Hawthorn. Immediately after the planting, which takes place in spring, the whole surface of the bank is covered with tan. Mr. Bruhns' experience with this material having shown that its application is beneficial in two ways, firstly, in destroying (without injury to the Thorn sets) those worst enemies of a young hedge, the weeds; and, secondly, in causing the soil to remain constantly moist and open, and, therefore, in a state favourable to the growth of the plants. The development of the latter should be further encouraged in very dry summers by watering the tan from time to time, especially in the case of small strips of hedge, enclosures of gardens, &c., where this can be done without great expenditure of labour. In a year from the planting, all the shoots but two well-matching ones on each Thorn are cut close off; the remaining couple being bent so as to cross one another. The two continue in most instances

Leaf of *Acer Pseudo-Platanus*.

in the position given them without being tied; sometimes, however, the grower is compelled to make choice of somewhat unfavourably-situated shoots, which require to be twisted into the line of fence, and he then fastens them with bast. During the next twelve months the hedge needs no further attention beyond keeping it clear of weeds, and moving the tan occasionally to ensure the surface remaining light and open. In the following spring the pruning and training are repeated; all superfluous shoots and branches growing out of the line of fence being removed, and the hedge cut down to a uniform height of 2 feet. The young Thorns will continue to shoot up vigorously during the second year, and in the third spring from the planting, must be bent and cut down to 38 inches. If a higher fence than this be needed, say one of 4 feet or over, the plants will have made more than the necessary growth by the fourth spring, and can then be reduced to the size desired. By following the above instructions, a neat and impassable hedge is thus created within four years, the crossed branches having become firmly attached and fixed in the direction given them. Should the grower desire to raise his own young plants, he must bear in mind that under ordinary circumstances the seeds will not germinate the first season. To avoid loss of time he will find it a good plan to put them, in the autumn, in a barrel containing a mixture of earth and quicklime. Seed so prepared, and sown in the spring, will at once vegetate. Q.

ON THE DIFFUSION OF GASES IN LEAVES.

THE phenomena of thermo-diffusion (studied recently by M. Feddersen), which occur when a difference of temperature is maintained between the two sides of a porous partition separating two portions of gas, and those phenomena of simple diffusion, which M. Dufour has observed between masses of air which differ hygrometrically, may also be observed in plant-organisms, where the circumstances are evidently favourable to their production. The subject has lately been studied by M. Merget, and he has communicated to the Paris Academy an account of his experiments and results, which presents various points of interest. Aquatic plants show the phenomena most distinctly, and it was *Nelumbium speciosum* that M. Merget chose for his investigations. To Raffeneau-Delille we owe our knowledge of the fact that, if the central concavity of a leaf of *Nelumbium* be covered with water, bubbles of gas will, on exposure of the limb to the sun, be liberated from the moistened surfaces, either by the stomates or by openings made artificially. This observer found, also, that the liberation of gas may also be produced by wounds made on the petiole, that it ceases with complete immersion of the limb, and that, when it occurs, it is atmospheric air that is given off. He concluded that each leaf of *Nelumbium* is provided with a complete respiratory system, the velvety surface being absorbent, and the stomates exhalant. From numerous analyses, M. Merget has verified the assertion, that the gas issuing from the leaves is atmospheric air (with some quite unimportant variations). He infers, that the phenomenon is quite different from chlorophyllian respiration, and produced exclusively by the solar heat-rays. So he thought to reproduce it by substituting an obscure heat source for the action of the sun. This may be readily done (he says) by using a circular sheet-iron plate, heated somewhat under red heat. It is, then, simply the difference of temperature between the parts of the limb directly exposed to the heat-radiation, and those parts which are protected by the layer of water, that causes the escape of gas included in the latter; and, for this gas to escape, in spite of the hydrostatic pressure, there must necessarily be an impulsive action proceeding from the neighbouring heated air. Accepting this explanation as plausible, it follows that the water in the centre of the leaf having simply the effect of guarding the subjacent tissues from the calorific action, a replacement of this by water hot enough to render uniform the temperature of the limb should stop the emission of gas by the moistened surfaces. This was tested and found to be the case. And there was more than this merely negative evidence; for, in some instances, when bubbles, being slowly liberated in the cold water, appeared to be held by a sort of gaseous pedicel, which kept them in communication with the mass of interior air, it was found, that on gradually adding hot water, the bubbles progressively disappeared, as if absorbed by the tissues again. On uniformly heating, at all its points, the upper surface of a leaf of *Nelumbium*, the air of its passages would thus be put uniformly throughout in a state of tension. To demonstrate this increase of pressure, M. Merget, having cut off a leaf, connected its petioles, by means of a caoutchouc tube, with a water-manometer. Then, exposing the limb to calorific radiations of various nature and intensity, he obtained a descent in the manometer of 1 to 3 decimetres. On detaching the manometer, the air of the lacunæ was set in motion, and, the petiole section being immersed in water, bubbles escaped from it abundantly. Thus, some leaves exposed to the sun gave a quarter of a litre of air per minute; others, exposed to a bright charcoal fire, one litre per minute, which is hundreds or thousands of times the volume of the leaf per hour; and this proceeded several hours without interruption, sometimes entire days. To maintain this expenditure, there must evidently have entered by the limb each instant a volume of air equal to that which left by the petiole, and M. Merget assured himself that this entrance was by the stomates, for the closure of these immediately arrested the liberation of gas. Atmospheric air is not the only gas which may be thermodynamically diffused through the limb of a leaf of *Nelumbium*; the author got similar results with oxygen, nitrogen, hydrogen, carbonic acid, carbonous oxide, and protoxide of nitrogen. The phenomena are thus to be regarded as determined by conditions of a purely physical order. From other experiments which he made, M. Merget thinks he is warranted in affirming that all plants show this thermo-diffusive power that is so remarkably developed in *Nelumbium*. As the heating of the leaf in the ordinary state is far from being produced uniformly in the parts struck by the solar rays, the interior air, by virtue of the excess of tension it acquires, presses upon that of the cold parts, forcing it to escape by the corresponding epidermic stomates, while the exterior air flows in by the stomates of the solarised surfaces. There is thus a real circulatory gaseous current from those green parts, which respire, to those which do not respire, with a double circulative movement of inspiration by the former and of expiration by the latter. In the aquatic plants, this

respiratory circulation has greater extent and depth than in terrestrial plants; for, instead of being circumscribed in the narrow network of passages in the foliar parenchyma, it is prolonged into that of the entire lacunar system.

A new Sea-side Plant (*Medicago arborea*).—Attempts are being made at Brighton to find some shrubs sufficiently hardy and well adapted to bear the exposed spray and winds of the new Undercliff Road, but, as yet, only two (the *Euonymus* and *Tamarisk*) have been found to stand the variations of heat and cold of that spot. Some years back I suggested to Mr. Spary, of the Graperies, Brighton, that the *Medicago arborea*, being entirely a sea-side plant, though a southern one, would be likely to stand the climate of Brighton, and he, in consequence, procured some seeds and raised several plants, which are now grown to large shrubs, and which may be seen in his garden, green all the year round, and for the greater part of that time bearing pretty yellow flowers; it is a remarkably handsome and very bushy shrub, and, being a sea-side plant, and growing so luxuriantly near the sea, it would, in all probability, thrive on the Undercliff Road, not only as a standard, but particularly also if trained up against the cliff wall: it may be seen growing 8 ft. high against the southern aspect of Mr. Balchin's cottage in his garden at Hove, as also against the north wall opposite; at Florence it forms beautiful hedges close to the sea. I trust that this notice may induce the authorities of Brighton, who are expending large sums in planting all over the town, especially on the Undercliff, where nearly all the trees so lately planted are dead, to try the *Medicago* there, which, if it succeeds, as I verily believe it will, cannot fail to be an attractive object and a most desirable addition to the shrubs of Brighton.—*Science Gossip*. [Have any of our correspondents noticed this shrub growing near the sea at Brighton or elsewhere?—Ed.]

Beech Blight.—Let your correspondents, who complain of the destruction of their trees by Beech blight, try, as a remedy, a mixture of common lime with water, in the proportion of three or four handfuls of lime to a bucket of water. This should be applied thoroughly over all parts of the tree affected, and, if the matter has not been neglected too long, and the disease allowed too great a hold, a cure is, I think, certain on a second application at most. I have for some years noticed this blight on the Beech, not only all over the United Kingdom, as I believe I may say, but on the continent as well. It is the excrement of an insect, and seems to be deposited on the Beech tree at almost all stages of growth. I do not think it is infectious, as I have noticed a diseased tree standing amongst others, which were perfectly free from the blight. Doubtless, however, there is usually some defect in the constitution of the tree attacked, or it would not be selected. Want of proper drainage in the soil is, I think, often the cause. A very fine Weymouth Pine, near the house here, was attacked some years ago with this disease, or something similar to it. The branches were, I think, principally attacked, and the tree was at one time nearly dead. I had it thoroughly cleaned with the lime-water mixture, and it has been wonderfully healthy and making large growth ever since. Many of my Beech trees I have treated in the same way, and, no doubt, their lives have, in some instances, been saved in consequence.—G. F. M.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Introduction of the Wellingtonia.—An expression appeared in last week's GARDEN (see p. 120), which might lead some to suppose that this Conifer was introduced by Messrs. Lawson, whereas, as is well known, it was introduced by Messrs. Veitch, through their collector, Mr. William Lobb.

Weeping Elms.—Can you give me the names of one or two of the most ornamental of these?—R. [The Weeping Wych Elm and the Camperdown, *Ulmus suberosa pendula*, *rugosa pendula*, *glabra pendula*, and *microphylla pendula*, are all ornamental kinds.—Ed.]

Tamarix plumosa.—Of this plant, M. Carrière writes as follows in the *Revue Horticole*:—Nothing can be finer or more graceful than this species, which is still so rare, in spite of the readiness with which it can be propagated. Its numerous, slender branchlets, of a glaucous green hue, bear a certain resemblance to the curled plumes of the ostrich (or the white stork) whence its popular name of "Marabout." It flowers in August, about the same time as *T. indica*. The flowers, which are disposed in dense erect panicles, have an airy lightness, which adds much to the elegance of the foliage. Isolated on a lawn, or in a large park, *T. plumosa* forms a compact mass of the most pleasing appearance. It is quite as hardy as *T. indica*, and is propagated and treated in precisely the same manner.

Chimonanthus fragrans from Cuttings.—In THE GARDEN of January 3rd (p. 18), it is stated that this has never been struck from cuttings. I beg to say that a few years ago I raised two plants of it from cuttings. They were taken during the summer, when the leaves had arrived at full growth, planted in light soil in pots, and placed in the shade in a Vinery. They were kept in a cool greenhouse all winter, and next spring, they pushed forth fresh leaves; one I gave away, the other I planted against a south wall, and it is now about 3 feet high, and in bloom. I have also a plant of it raised from seed, which ripened here in the open air, about three years ago, but has not flowered up to the present.—MARY FREEMAN, Ryton on Dunsmore.

THE FRUIT GARDEN.

RASPBERRY CULTURE.

MR. TAYLOR says (see p. 123) that a plantation of Raspberries is only just coming into bearing at five years old, and that he should expect it to continue in good condition for twenty years at least. It has been too much the custom to look upon a plantation of Raspberries in the same light as one regards an orchard of fruit trees, viz., that it should be planted only once in a lifetime. I contend, however, that most of the permanent crops in a kitchen-garden, such as Raspberries, Globe Artichokes, Rhubarb, &c., would not only be much benefited by being more frequently transplanted, but that the operation would also liberate more land for the rotation of other crops, and I need not say how desirable it is to have a fresh piece of land for Potatoes, for instance. If good strong Raspberry canes are planted, they ought to bear a good crop the second year, and in the third year they will be at their best; but if weakly canes from an exhausted plantation have been used, then, I grant, several years must elapse before they will bear well; but this only illustrates one of the evils to be apprehended from the system of not making a new plantation till the old one fails. Of course, I don't desire to tie anyone down to any hard or fast line, as local circumstances may, and probably will, have great influence in determining how long a plantation shall remain on the same spot. I simply recorded my own practice, and, if anyone likes to follow it, I am sure that they won't regret it. In condemning late summer and autumn Raspberries, Mr. Taylor, I think, looks at the subject only from a market-gardener's point of view, while in a private garden a man's success or failure depends, more frequently, upon his ability to produce a steady and continuous supply, rather than a large quantity at any one time. Of course, under any circumstances, where Raspberries are grown largely, the largest quantity of fruit will be ripe for preserving in July; but it is quite as important, in many establishments, to provide a succession of fruit from that time onwards till October. I readily admit that, as the sun declines in power, Raspberries will be less sweet; yet, notwithstanding this, there is always an agreeable freshness and piquancy about the flavour of Raspberries which renders them especially useful and much sought after for tarts, puddings, ices, &c., and also for being eaten with cream and sugar, the same as Strawberries, whenever obtainable. I have never known Raspberry canes to be seriously injured by frost in winter; nor is it likely to happen if the young canes are strong and well matured, which they will be if managed according to the mode of culture I recommended. Spring frosts in May may sometimes injure the young growths; but, even then, any serious injury to the crop from such sources is not a common occurrence. I quite agree with Mr. Taylor that heavy clay-land is not the best land for Raspberries, although they may even be grown on such soils successfully. Burnt earth and old mortar-rubbish make a capital dressing for such land, and are especially suitable for Raspberries.

E. HOBDAV.

Barchard's Seedling Apple.—This, says the *Florist and Pomologist*, is neither a new nor very old variety. It was raised by Miss Barchard, of Putney, some forty or fifty years ago, and has been frequently brought under notice in one way or another, but has never yet taken that prominent position to which its merits so fully entitle it. Mr. Thompson mentions it in the Catalogue of Fruits of the Royal Horticultural Society. It was awarded a certificate by the Pomological Society some years ago, and now, at last, it has received the same honour from the Fruit Committee of the Royal Horticultural Society. We have specially to thank Mr. F. Dancer, of Little Sutton, Chiswick, for showing us the full merits of this thoroughly excellent Apple. Near Gunnersbury Station may be seen a group of some forty or fifty good-sized trees of this variety, which every autumn presents a most beautiful picture, laden as they are with bright, shining, rosy-cheeked fruit. The trees themselves are of a fine free style of growth, and form objects of quite an ornamental character. The fruit is of medium size, of the Nonesuch shape, flattened at each end. The eye is open, set in a deep plaited basin; the stalk is about an inch long, and rather deeply set. The skin is of a clear greenish-yellow on the shaded side, very much suffused and streaked with red and bright scarlet on the exposed parts, this high colouring giving it, especially when hanging on the tree, a

very beautiful appearance. The flesh is firm, of a pleasant sub-acid flavour, tolerably good for dessert, but more valued for cooking purposes. It is in season from October to Christmas, is an almost certain and most abundant cropper, and is greatly to be recommended as a standard orchard fruit.

Seedling Apple Lady Henniker.—This valuable addition to our list of Apples was deservedly awarded a first-class certificate at the autumn show of the Royal Horticultural Society last year. Its great merits will certainly commend it to a place in every collection, and it only requires to be brought before the public to become a leading standard variety. As a kitchen Apple, it is one of the very best and largest with which I am acquainted, and it keeps in good condition from October until March. As a dessert Apple, too, it is very valuable, and, being of a rich waxy-yellow, streaked with crimson, it has a fine appearance, especially under artificial light. It is a selected seedling from several hundreds raised about thirty years ago, at Thornton Hall, Suffolk, the seat of Lord Henniker. Mr. Jno. Perkins, the present gardener there, informs me that it has for years past been their most favourite Apple for culinary purposes. It has not, therefore, been hastily brought forward, but has rather, as it were, put itself forward by the best of all recommendations—its own merits.—J. GROOM, *Henham Gardens, Wangford.*

Woollen Refuse or Shoddy as Bottoming for Vine-Borders.—This is one of the best materials with which I am acquainted for covering rubble in the bottoms of Vine borders, especially when it can be had long in texture, and before the oil is pressed out of it. When such is the case, it is almost indestructible, and when pressed down by the superincumbent soil, it becomes like a piece of felt, preventing the smallest particle of soil from passing through it; besides, if the borders are watered with liquid-manure, it acts as a filter. On widening a Vine-border, the rubble bottom of which had been covered over with this material to a depth of 2 inches, I found the fibrous roots of the Vines so thickly interwoven with the woollen refuse, that they would of themselves have prevented any soil from passing through them. I used the same material for covering my Pine-pits and Melon-house (which is exactly such a house as that described by Mr. Simpson, the other day, in *THE GARDEN*), and I am surprised that it is not more extensively used than it is, especially in counties where it can be had so abundantly. I have known Heather or Ling used for bottoming borders. Any material that allows air and water to percolate freely through the soil to the rubble-bed beneath, is, in my opinion, better than slates; indeed, a small thin soft-burnt tile is preferable to them.—J. T.

Hybrid Apples.—The introduction of the Siberian Crab is destined to work a great revolution in the Apple kingdom, by crossing with the common Apple. The Crab seedling appears to hold well to its parental hardiness, be the cross what it may, and the tree an Apple in all its parts, with fruit enlarged without the tincture of Crab. It is but a small percentage of Crab seedlings that show tenderness from the cross, and in fruit they enlarge at a rapid ratio, with occasional bounds to an extreme at once, as in case of the Wealthy Apple from Crab seed—Apple in tree but hardy as a Crab—fruit large and unsurpassed in beauty and flavour. Similar results have attended the planting of seeds from Cherry Crab—a fair-sized, perfect Apple, without tincture of Crab; while on the other hand, we have grown Crab fruit from Duchess and Wealthy seed, and occasionally a perfect Crab tree from the seed of each. In appearance, we have perfect Blue Pearmain trees from Crab seed, not yet fruited, but enough of the hybrids have fruited to determine pretty closely what the fruit will be. The seedlings on which we most rely are not yet in bearing; only about thirty have borne, with near 2,000 to come in yet—the smallest being best, most favourably situated for a good cross, and of the results we have no fear. Our motto is:—Seeds from the most perfect tree, crossed with the very best in fruit—the most hardy preferred, if good in size and quality.—*Cultivator.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Chickasaw Plum.—The Chickasaw Plum, or *Prunus Chicasa* of botanists is a distinct species, growing wild in the South-Western States. It generally reaches a height of from 8 to 15 feet, although on the sandy plains it merely forms a dwarf round bush. The fruit is small, roundish, red, and of a pleasant flavour with a rather acid juice. We do not know of any first-class, or even really good, varieties from it; still, like most other species, we presume it is liable to sport into many forms, some of which may produce better fruit than the parent.—*Tribune.*

Dimorphism in the Apple.—The following communication on this subject from M. Chas. Baltet, of Trôyes, appears in the *Revue Horticole*:—"For the last three years a Boston Russet here, trained as a two-branched horizontal cordon, has borne, on one branch, fruit of the red and grey colour proper to that variety of Apple, while the fruit on the other branch are entirely green, without the least tinge of red. In winter, when the fruit is getting ripe, the skin of the latter changes to a golden-yellow, while those on the other branch retain their red colour, the grey ground changing to golden-yellow. The flavour of the red-skinned fruit is, also, somewhat more acid than that of the others."

GREEN'S WROUGHT-IRON BOILER.

THIS boiler has been tried by the Royal Horticultural Society, both at South Kensington and at Chiswick, and has given entire satisfaction. At Chiswick, it heats two ranges of plant-pits, containing 780 feet of 4-inch piping, with remarkably little fuel, and it requires no more attention than the old "Saddle" boiler. One of a large size fixed at South Kensington for heating the great conservatory, has attached to it 6,264 feet of 4-inch piping and 375 feet of 6-inch piping, all of which it heats most effectually. The quantity of fuel required is from nine to twelve sacks of coke every twenty-four hours, according to the weather. The principle on which these boilers are constructed will be seen at once by a glance at the accompanying sections. The fuel rests on the hollow water-tubes, which form the fire-bars, and these bars are connected with the water-space of the boiler by a double elbow-pipe at the back of it. The heat and smoke pass forward and play against the water-space at the back and on the shelves, which are now made bull-nose in shape, so that, where the greatest volume of water rests, the heat acts directly upon it, and passing between the shelves to the arch or water-space at the top of it, is almost completely exhausted before it enters the flue. The flow is from the top, and any number can be put on, while the returns come in on each side of the framework of the bars in front. The doors slide open from the centre or middle of the front to each hand, which is a great advantage. They are opposite the spaces between the shelves, so that the boilers can be easily cleaned. One of these

CROSS SECTION.

LONGITUDINAL SECTION.

FRONT ELEVATION.

Green's Patent Wrought-iron Boiler.

boilers is doing good work at the present time at Messrs. E. G. Henderson's, where the fuel used for it is small coal and clay mixed. An advantage belonging to these boilers is, they do not require setting in brickwork, and can be set to work at a mere nominal cost. They are made entirely of wrought-iron plates of a uniform thickness, well rivetted together; consequently, the expansion and contraction are regular and equal throughout, and hence their superiority over welded or cast-iron boilers, which vary in thickness, as well as in expansion and contraction. They require little room, and can be put in places where other boilers could not be fixed. The chimney may be made of cast-iron, and can be taken inside and up, either through the roof at once, or converted into a flue, according to the situation in which the boiler is fixed.

J. M.

Cowan's Lime-kiln Boiler.—With reference to Mr. Bennett's article on the "Gold Medal Boiler," published in your issue of the 27th of December, Mr. Bennett appears to have stated that the boiler used by him at present over the lime-kiln is the Gold Medal Boiler. This is a mistake, as the boiler in use there over the kiln is my own special invention, used by me in connection with my patent apparatus. I have written to Mr. Bennett on the subject, and he states the error to be yours. I therefore hope that you will kindly set the matter right, as my boiler is pronounced by all who have used it to be a very efficient one.—JOHN COWAN.

THE LIBRARY.

A MANUAL OF BOTANY.*

THE value of this manual is sufficiently attested by the fact that the whole of the second edition was sold in a little over two years after its publication. In the present edition the text has been thoroughly revised, several new wood-cuts have been added, the type has been enlarged, the size of the page somewhat increased, and much new matter has been introduced; yet, by judicious curtailments in some unimportant particulars, the bulk of the volume is somewhat less than in the previous editions. The work is divided into three books, the first of which treats very fully of the structure and morphology of plants; in the second book, the various systems of classification are detailed, and an arrangement is given of plants in their natural orders (based on the system of De Candolle). This part of the work is particularly valuable on account of the excellent notes appended to the descriptions of each order, and explaining the economic, or medicinal properties and uses of every important species. The third book gives an outline of the physiology of vegetation—a subject too extensive to be properly treated of in the concluding pages of an already tolerably large volume. In a future edition, however, Mr. Bentley may amplify this part of the work and make it the subject of a second volume, which might also include a treatise on descriptive botany and a glossary of botanical terms. Of the 1,138 wood-cuts in the present edition, we regret to observe that many

have lost their original clearness and sharpness of outline, and look somewhat "used up."

FOODS.†

THE main design of this work is to present to its readers a carefully executed comparative analysis of the nutritive and other special properties of the various solids and liquids which are every day called into requisition for the support or comfort of the human frame. The dyspeptic will find it, in this sense, a "Minister of the Interior," inasmuch as it points out very distinctly the precise proportions, in all kinds of food, of gluten, starch, albumen, essential oils, &c., any of which may have been his proper bane; and so, correlating himself with the deductions of Dr. Smith's experience, he may safely venture on the question of "what to eat, drink, and avoid." The work, throughout, is essentially analytical, and bears testimony to the careful investigation of the author, as well as to the love of his subject, which in any writer is, more or less, a guarantee of his faithfulness. Commencing with the higher order (as they are commonly considered) of articles of food, Dr. Smith successively tabulates the constituents of all the meats, fishes, and vegetables which, in various shapes and guises,

* "A Manual of Botany, including the Structure, Functions, Classification, Properties, and Uses of Plants." By Robert Bentley, F.L.S. Third Edition. London: J. & A. Churchill. 1873.

† "Foods." By Edward Smith, M.D., LL.B., F.R.S. Second Edition. London: Henry S. King & Co., 65, Cornhill; and 12, Paternoster Row. 1873.

make their daily appearance at the family table. Thence he passes on to an elaborate consideration of the good or evil effects of alcoholic liquids. As an example of the manner in which Dr. Smith handles his various subjects, we subjoin the following short extract:—

Potatoes.

"The relative value of Potatoes is determined in a general manner by their specific gravity, just as a similar estimation is made of an Apple or an Orange by weighing it in the hand, for, the heavier in relation to bulk is any given Potato, so is the greater amount of starch. If several Potatoes be thrown into a solution of salt, and water be added until some of them sink and others swim, the specific gravity of the saline solution will be that of the Potatoes as a whole. J. J. Pohl found the following relation between the specific gravity and the proportion of starch:—

Sp. Gr.	Starch in 100 parts.	Sp. Gr.	Starch in 100 parts.
1.090	16.38	1.107	20.45
1.093	17.11	1.110	21.32
1.099	18.43	1.123	24.14
1.101	18.98		

"The quantity of ash or saline materials present in 100 parts of the fresh Potato, varies with the kind, as shown by T. J. Herepath. Thus:—Fortyfold, 0.88; Prince's Beauty, 1.06; Maggie, 1.09; Axbridge Kidney, 1.27; White Apple, 1.30. The proportion of potash in the salts of Potato is very large, and does not vary much in the several specimens examined, the limits being 53.03 per cent. in the Fortyfold, and 55.73 per cent. in the Maggie. Potatoes are deficient in mineral matter, so that they are unfit to be a sole food, but that defect is supplied by the addition of hard water, milk, and other elements of food. There are 760 grains of carbon and twenty-four grains of nitrogen in 1 lb.; so that more than 2½ lbs. of Potato are required to equal 1 lb. of bread in carbon, and more than 3½ lbs. in nitrogen. Hence, when Potatoes are 1d. per lb., and bread 1½d. per lb., the former are two to three times dearer than the latter, but the former are valuable for their juices in addition to their nutritive elements. New and waxy are said to be less digestible than old and mealy Potatoes, but the time required for digestion may be regarded as nearly the same as for bread, viz., from two-and-a-half to three-and-a-half hours. Ten grains of Potato consumed in the body produce heat sufficient to raise 2.6 lbs. of water, 1° F., or to lift 1,977 lbs. 1 foot high. The water in which Potatoes have been boiled is not used as food, for it is not only nearly destitute of nutritive matter, but is said to contain substances which are deleterious to health. In my experiments, the effect of eating good Potatoes, whether new or old, was less than that of rice. In two experiments, 8 oz. increased the carbonic acid evolved in the respiration by 1.27 grains per minute, and the quantity inspired by 52 cubic inches per minute. The rate of pulsation and respiration was slightly lowered."

HEDGES.

APART from their general utility, there are few things that add more to the appearance of a garden than good hedges. With garden hedges there is generally a twofold object to be kept in view—their utility and their appearance. Numbers of plants are, and have been employed for garden hedges, such as Holly, Yew, Beech, Privet, Thorn, Laurel, Arbor-vitæ, Rose, &c.; or a mixture of some of these, such as Beech and Privet, Holly and Thorn. For general utility, however, combining strength, duration, adaptability to most soils, and price, Thorn has no equal; but, for appearance, nothing excels the Holly, its price only being a serious consideration where required in quantity, as, in planting for hedge purposes it is necessary to use the Hollies in a much older state than would be necessary in the case of most other plants. The common Yew makes a noble hedge, but it has the fault that in some soils it dies, if it is kept cut in to the size that some other plants will bear without injury, and, if it is required in quantity, it becomes expensive. In dry situations, such as when it is planted on the top of a dry bank, it also, sometimes, suffers severely in very dry summers. Another very important consideration is that the Yew is poisonous to cattle, consequently it should never be employed except where there is no likelihood of cattle coming near it.

Holly Hedges, and Preparation of the Ground for them.

The Holly, then, is the plant for a garden hedge where appearance and use are both essential objects. It is so far an accommodating plant, that it will grow on soils the most different in character—on such as are extremely open and sandy, and also on those of a much heavier nature—the first essential being that they are sufficiently dry; anything approaching stagnant water the Holly cannot bear; consequently, where the situation is too wet, draining must be the first operation. In draining, preparatory to the planting of any hedge, more than ordinary care should be taken that the work is so carried out that it will not only be effectual from the first, but so

constructed that there will be some likelihood of its continued efficiency. In the size of pipe used we must be ruled by the distance to be drained, and the volume of water to be carried off. In most situations a 4-inch pipe will be sufficient, and a depth of 3 feet to 3 feet 6 inches will be generally found to be the best. To prevent the roots of the hedge plants choking up the drain, over the pipes should be laid 6 inches of rubble. The Holly is a manure-loving plant, and there is nothing with which I am acquainted that will better repay a liberal application of good rotten farmyard dung. Previous to planting any hedge, the ground should always be thoroughly well dug 2 feet deep, if the soil is sufficient in depth to admit of such a depth. After this, 6 inches of manure, 3 feet wide, should be laid on, and well worked in, a foot deep. The size of the plants to be used will be regulated by the object in view; it is simply a question of cost. If the extent to be planted is limited, and immediate effect—such as shutting out anything of an objectionable nature—is desirable, the plants employed may be 6 feet or even more in height. For ordinary work 12 to 18 inches may be considered the most useful size, but whatever sized plants are used, care should be taken in the selection that they are such as have been periodically transplanted, so as to be in a condition to move well. This is of more importance than absolute size. The necessity for allowing no more time to elapse than is unavoidable betwixt their being taken up and re-planted is of importance with Hollies, as with all other evergreen plants; as also the desirability of keeping their roots from exposure. This will be obvious when we recollect that the roots of an evergreen plant are taxed by the evaporation continually going on through the leaves, even when no active growth is in progress.

When to Plant, and After-management.

The time for planting is of the greatest importance. If, in the circle of the year we can select a time when there is no growth going on—when the leaves and wood are matured, and of such consistency as to considerably reduce loss by evaporation, and also when the roots are in such a state as at once to commence growing after re-planting, and so repair the balance destroyed in the operation of removal—that, of all others, must be the time to remove all evergreen plants. It is in September and October that we find these necessary conditions to exist; hence these months are much to be preferred to all other times in the year for the removal of all evergreens, although some say Hollies should be planted in spring. At the time of planting, when about half the soil is filled in over the roots, give a thorough soaking with water, so as to moisten all the surrounding earth; after that they will not require more, for the autumn rains will, from that time, supply all that will be wanted. If the work is carried out in this way, the plants will commence growing at their wonted season in the spring, with losses of not more than one in fifty, as compared with spring-moved plants. In April put a mulching of two or three inches of dung over their roots, and keep them quite clear from weeds. They will, during this season, make a few inches of growth; but, if all goes well, the summer following they will push their leading shoots a foot or more; they will require little use of the shears or switching-hook (the latter being the better tool of the two), for two or three years, except shortening the leading shoots, and any side-branches that may push away too strongly; the great thing is to keep them quite free from weeds, and to give them every spring a good mulching of dung, until the hedge is as high as it is required to be. After four years' growth it should be kept in proper shape by means of the switch-hook. Round-topped, or, still worse, heavy square-topped hedges, as wide, or wider at top than at bottom, are wrong from every point of view; they are heavy, unmeaning-looking distortions, representative of a style of gardening happily all but extinct. No matter what plant is used for hedge purposes, the shape in which to keep it, whether for appearance or the well-being of the hedge, is that known as hog-maned, which, as is generally known, is the widest at the bottom, getting gradually narrower, very slightly rounded, until it comes almost to a point at the top. For most purposes, in a garden as a screen, or break, or for use as a fence, 4 feet wide at bottom, and 6 feet 6 inches or 7 feet will be found a useful height. The yearly cutting necessary to keep such a hedge within the required size should be done about the beginning of April; and, if ever allowed to get too large, necessitating a considerable reduction, it should be carried out about the same time; if done late in autumn, or in winter, if a very severe frost occurs, it sometimes kills the wood back several inches; but no hedge should be allowed to get larger than the object for which it is intended requires.

Yew, Beech, and other Hedge Plants.

The common Yew is also well adapted for hedge purposes, where it may grow naturally without a trace of the pruning-hook; it spreads horizontally, much more than Holly, covering more ground, but it is better adapted for a wide hedge than for forming a narrow

screen. If ever it is allowed to get too large, and has to be cut hard back into the strong wood, it is liable to die; consequently, wherever Yew is used it should never be allowed to increase much yearly. Where a high screen is required, or shelter hedges for nursery stock in exposed situations, Beech is often used, and is very effectual from its disposition, when kept cut, to retain its old leaves through the winter. This latter disposition is an objection near dressed ground in a private establishment, owing to the litter it makes in spring. The old variety of Privet used to be often mixed with Beech in planting; the Beech giving strength to the weak-growing Privet. For a screen fence in a garden, where small expense, combined with speedy effect is a consideration, nothing surpasses the new oval-leaved Privet. This is an exceedingly vigorous-growing plant, strong enough for a fence without mixing with Thorn, Beech, or any other plant to give it support. On good well-prepared soil, it is a most rapid grower, making shoots almost as thick as the little finger, 3 feet long. I have a screen fence of it, planted four years ago, now 6 feet 6 inches high, densely feathered down to the ground, and it is as large and perfect in every respect as can be desired. Arbor-vitæ, both the American and the Chinese varieties, are sometimes used for screen hedges; the latter is much the best, being neat in appearance. Where immediate effect is required, it can be had at once by the use of these plants, but where anything more than a mere screen is required they are useless, as their weak upright habit of growth renders them of no use as protecting fences; they can be pushed aside, and walked through at pleasure. The Irish Yew makes a nice screen, costs much more than the Arbor-vitæ, but it is superior in appearance. Where this plant is used, care should be taken to select those that have been confined to one leading shoot, as, if left to itself, it forms a number of leaders of equal strength, and, when the plant gets large, it is liable to be split in all directions by the wind or heavy snow-storms. Where a more compact hedge is wanted for a break not too high, the Rose is a most suitable plant, and not near so much used as it deserves to be. The blush and crimson Chinese make a beautiful light hedge, and are lovely when in flower. Very severe frosts are liable to kill them down to the ground, but they push up again from below the surface quickly, almost re-establishing themselves in a season. Any of the strong-growing perennials are even more suitable for this purpose than the Roses. I could not imagine a more beautiful sight than a hedge of Glory of Waltham laden with its magnificent crimson flowers.

Planting and Management of Thorn Hedges.

For orchards, vegetable ground, or anything connected with the garden, requiring a cattle-proof fence, there is nothing equal to Chinese Quick, and in such situations it is worth while to bestow a little extra labour on the preparation and planting, so as to obtain a fence that will be a protection in every sense of the word. With a thorough preparation of the ground, and good Quick, well planted at the proper season, and well cared for afterwards, in a few years a fence will be in existence more formidable to either biped or quadruped than any ordinary wall. Let us first consider the nature of the plant of which we are treating. First, it must have a dry bed in which to grow; it is perfectly useless to plant it where there is anything approaching stagnant water in the soil; consequently, if the land is not dry enough, it must be made so, either by an open ditch or covered drain. Next, it is a plant that will bear any reasonable quantity of manure. If the soil is shallow and wet, I should recommend a ditch to be formed on the outside of the hedge. It should be made 3 feet wide, sloped out to nothing, and 1 foot deep at the side next the hedge; the soil taken out goes to raise the bed on which the hedge is planted, elevating it in a way that precludes its suffering from stagnant water. The ground should be trenched 18 inches deep, and 4 feet wide, with 6 inches of rotten dung well worked into it; this work should be done in autumn, if possible, before the land gets saturated with rain; it will thus be in a much better state for planting than if deferred until late in the winter. Planting should never be delayed, as is often done, until the buds have begun to swell; the sooner after Christmas it is completed the better. In selecting Quick, mere size should never be the first consideration; on the contrary, choose robust stocky plants, that have been twice transplanted, and the last time not too long before the final planting. Large old Quicks, that have stood for years without being moved, are all very well to tempt the inexperienced planter; but he afterwards finds out that they are some time before they make much progress, smaller plants, in proper condition for planting, far outstripping them. For such situations as those under consideration, I should recommend a double row of Quick, 1 foot apart in the row, and a similar distance betwixt the rows. In planting, angle the plants thus The practice of heading down to about 6 inches from the collar, at the time of planting, is still carried out by some, but it is a bad practice; plants so treated make wretched growth the first year, and correspondingly little root progress, to enable them to make more than half the

growth they should do even the second year. Heading the plants down to within 6 inches of the ground is a most essential operation, but they should never be so treated until they have had a year's growth after planting, and then it should be done in the winter, before the buds begin to push, using a good sharp pruning-knife for the purpose, always cutting upwards, so as to leave the stools smooth and clean. This cutting back is to cause each plant to break a number of shoots, instead of running away with one leader, leaving the hedge thin at the bottom. To the non-initiated it often seems a pity to cut them back in this way, and appears a waste of time; but the omission is fatal to the hedge ever acquiring the first essential—a thick close bottom. When headed down as described, this double-row fence will break back so thickly as to be almost fowl-proof, and, by the autumn of the second year after planting, will be at least half a season's growth ahead of the fence that was beheaded at the time of planting. In the autumn of the second season after planting, any time after the leaves have fallen, the growth should be cut back to within a foot of where they were headed back to the previous winter, always using the switch-hook in preference to the shears. If all goes on well, the fence will each season make rapid progress, branching out and getting strong. Every autumn go over it with the hook, cutting back to within a foot of the preceding year's cutting, always preserving the hedge widest at the bottom, gradually tapering up to a point at the top. No other form of cutting will keep a fence full and thick at the bottom, which this does by counteracting the natural tendency of the plants to run too much to a head. Local circumstances will regulate the height. A 6-foot fence for such situations as those under consideration is a good height; but there is no objection to one even higher than this. But it must be borne in mind that, the higher the fence is allowed to grow, the wider it must be at the bottom; otherwise it will there get weak and thin. A hedge 7 feet high must not be under 4 feet 3 inches wide at the base. When full size has been attained, it must, at every pruning, be cut right back as near as possible to where the hook went at the preceding cutting; otherwise it will soon get too large, which would require its being cut back into the old wood, giving it for some time an unsightly appearance. I have, as yet, said nothing about the usual paling to protect the young growing fence from cattle. When it is situated where it will be liable to injury from this cause, the paling must be put up before the Quicks are planted. One of the principal things to be kept in view is to get the young hedge on so that it will be a sufficient fence before the paling is worn out and requires renewal. Neither have I alluded to the all-important matter of keeping the young Quicks perfectly free from weeds, especially during the first two years; but, where this is not attended to, it is useless to expect them to thrive. If, after the second year, the hedge does not make satisfactory progress, being at all weak, in spring, before growth commences, give it a good top-dressing of farm-yard manure; this, unless there is something wrong in the soil, through its being too wet, or other local cause, will push it on.

Renewing Worn-out Hedges.

We often hear it said that Quicks will not grow in the same soil from which an old hedge has been removed; and, if the old hedge has simply been grubbed up, and the young Quicks planted without further preparation, it will certainly not thrive any more than any other crop would under such conditions. No, when an old hedge is removed, it must be done thoroughly, not leaving quantities of old roots in the soil to decay and breed Fungus to attack the roots of the newly-planted fence. The ground must be properly trenched, working into it plenty of manure as far as the roots of the new Quicks are likely for some time to extend. Select, plant, and, above all, keep the young fence perfectly clean from weeds, and mulch the surface with a little manure every spring, until the hedge gets up. In short, give it similar attention, with a little more manure than would be considered necessary for any fence newly planted, where none other had previously existed; and there need be no misgivings as to the result. This re-planting exactly on ground previously occupied by old hedges more particularly applies to boundary fences, where there can be little or no deviation from the old line. Where divisional fences are worn out, it is often practicable to prepare for and plant the new fence on the opposite side of the ditch, or even further to deviate from the old line, which frequently presents other advantages, in addition to new soil for the Quicks. We frequently hear it said that this making new fences, with the railing required to protect them until grown to the required size, is an expensive job. True, it is; but where hedges that cannot be altogether dispensed with are worn out, there is no resource but either to keep on expending labour and material in a way that produces the most unsatisfactory results, or set to work and do the thing in the way that will be the cheapest and most satisfactory in the long run.

Mention was made in THE GARDEN last week of tan being employed for mulching newly-planted Quicks in Holstein. In the north of

England this is often done. It effectually prevents the growth of annual weeds without injuring the Thorns, unless put on too thickly; about 2 inches is the proper quantity to use, and a second application is necessary the second year.—*Field*.

THE HOUSEHOLD.

BREAD.

The ultimate chemical composition of English bread, made from good seconds flour, is, besides oxygen and hydrogen, per cent.:—C., 28.5; N., 1.29. The proximate elements in 100 parts are:—Water, 37; albuminous and allied substances, 8.1; starch, 47.4; sugar, 3.6; fat, 1.6; salts, 2.3. The quantity of nitrogen and carbon in 1 lb. of bread, baked in the ordinary English manner, is 92 and 1,968 grains. The time required for the digestion of bread is 3½ to 4 hours. Ten grains of dryish bread, when burnt in the body, produce sufficient heat to raise 5.52 lbs. of water 1° F., which is equal to lifting 4,263 lbs. 1 foot high. The effect of eating 4 oz. of white home-made wheaten bread was to give maxima of increase in the quantity of carbonic acid evolved of 1.48 grain and 2.4 grains per minute on different persons. The quantity of air inspired was increased by 60 cubic inches per minute. The influence was very enduring. The law of this country inflicts penalties for the adulteration of bread, and prescribes that when ordinary bread is sold over the counter it shall be sold by weight, so that a quarter loaf shall weigh 4 lbs, and half a quarter loaf 2 lbs.; and the price of the loaf varies only with the price of flour. This subject has always attracted the attention of Governments, so that in the reign of Edward IV. we find it stated that the Lord Mayor "did sharpe correction upon bakers for making bread otherwise than of floure, and light of weight, and caused divers of them to be put in the pillory." At a later period the assize of bread by the Court of Mayor and Aldermen of London prescribed the weight and price of bread, as shown in the following precept, copied from a bill of mortality, No. 28, London, Tuesday, the 27th day of June, 1775:—

"WILKES, Mayor.

"London, { The Assize of Bread, set forth this 13th day of June, 1775, by order of the Court of Mayor and Aldermen of the said city, to commence and take place on Thursday next, and to be observed and kept until the further order of the Lord Mayor of the said city, or the said Court of Mayor and Aldermen, by all persons who shall make, or bake for sale, any bread within the jurisdiction of the said Court of Mayor and Aldermen, that is to say,

	lb. oz. dr.	
The penny loaf, or two half-penny loaves, to weigh.....	{ Wheaten 0 8 11	
	{ Household ... 0 11 9	
The two-penny loaf	{ Wheaten 1 1 6	
	{ Household..... 1 7 3	
The three-penny loaf.....	{ Wheaten 1 10 1	
	{ Household..... 2 2 12	

"To be sold for—

	lb. oz. dr.	s. d. f.	
The peck loaf, to weigh }	17 6 0	{ Wheaten 2 8 0	
		{ Household 2 0 0	
The half-peck loaf ... }	8 11 0	{ Wheaten 1 4 0	
		{ Household 1 0 0	
The quartern loaf ... }	4 5 8	{ Wheaten 0 8 0	
		{ Household 0 6 0	

"NOTE.—All loaves, if complained of, must be weighed before a magistrate within twenty-four hours after baking, or exposing thereof to sale, and must be according to the respective weights in the above table. Sixteen drachms make an ounce, and sixteen ounces a pound.

"ITEM.—It is hereby ordered and appointed that no person within the jurisdiction aforesaid shall, after Wednesday next, until the further order of the Lord Mayor, or of the said Court of Mayor and Aldermen, make, or bake for sale, or sell, or expose to or for sale within the jurisdiction aforesaid, any half-quartern loaves. And the better to distinguish and ascertain the two sorts of bread hereby ordered to be made, one from the other, there is to be imprinted and marked on every loaf of bread which shall be made, sold, carried out, or exposed to or for sale within the jurisdiction aforesaid as wheaten bread, a large Roman W; and on every loaf of bread which shall be made, sold, carried out, or exposed to or for sale within the jurisdiction aforesaid, as household bread, a large Roman H. And the penalty for every omission is twenty shillings. R. I. X.

"The price of salt, set by order of the Court of Lord Mayor and Aldermen, dated the 21st of October, 1735, is five shillings the bushel, 56 lbs. to the bushel, and so in proportion for any lesser quantity; and whoever shall sell at a higher price, or shall refuse to sell at the price aforesaid, forfeits five pounds."—*Dr. Smith on Foods*.

WORK FOR THE WEEK.

PRIVATE GARDENS.

Conservatories.—Between forced plants and such as bloom naturally at this season, conservatories are now well furnished with flowers. In addition to Hyacinths and other bulbous plants, these also contain blooming plants of Camellias, Azaleas, Chinese Primroses, Cinerarias, Salvias, some Zonal Pelargoniums, Daphnes of different kinds, Cytisus, Zieria Smithii, several Acacias, Heaths, Epacrises, Boronia serrulata, Libonia floribunda, Tremandra verticillata, Correa cardinalis and Brilliant, Monochætum sericium multiflorum and ensiferum, Lachenalias, Roella ciliata, Oldenburgia Depiana, Pyrethrum uliginosum, Leucopogon lanceolatus, and Luculia gratissima. Amongst climbing plants, Hibbertias, Kennedyas, Hardenbergias, Brachysemas, &c., are now coming beautifully into flower. Amongst dwarf climbers, nothing is prettier at present than nice plants of Myrsiphyllum asparagoides, loaded as they are with a profusion of little reflexed white flowers, having orange-coloured conspicuous anthers. This is a plant that may be readily raised from seeds sown in a hot-bed, pricked or potted off singly when up, and kept growing in moderate heat or in a cool house; either will do, only when a little warmth is employed good plants are sooner obtained than by cool treatment. Pot such roots as remain of Primula cortusoides in a compost of good loam two parts and leaf-mould one part, with a little sand. Those previously potted and beginning to grow, keep on a shelf as near the glass as possible. Give a final shift to herbaceous Calceolarias, and also to some of the shrubby ones intended for conservatory decoration. Cinerarias required for late blooming should have plenty of root-room and water, and be kept in a cool, airy house. The least confinement of the roots is sure to cause the plants to flower prematurely. A few Balsams and Cockscombs for early flowering should be sown in a hot-bed, and pricked off before they become spindly. Of Amaranthus salicifolius a few seeds should likewise be sown for conservatory ornamentation, as well as for flower-garden decoration. To succulents starting into growth water should occasionally be given, so as to keep the soil moderately and uniformly moist. The general potting of greenhouse plants should now be proceeded with. Begin with those that have commenced to grow, and which are most forward, having the ball moderately dry, and the soil used in potting in a similar condition. Do not give water after potting to such plants as have been at rest or kept comparatively dry during the winter, until they show that they need it. From Cinerarias, Calceolarias, &c., water must not, however, be withheld. In potting, make the new soil as firm as the old, otherwise it only forms a channel for the water to run through without penetrating the old soil, thus greatly impairing the health of the plants.

Indoor Fruit and Forcing Department.—For Pines, prepare a good stock for potting, and lay it under cover for some time prior to using it. Water the plants but sparingly, avoiding too much drought, or, on the other hand, a soddened condition of the soil. For stock plants a night temperature of 70° and a bottom-heat of 80°; 10° lower temperature will be quite enough for succession plants, which should not be excited till the end of the month. No Vines should be allowed to carry any of last year's fruit till now, and, if any bunches are still hanging on them, they should be cut off at once, with pieces of the wood attached to them, inserted in bottles of water, and kept in the fruit-room; this allows the Vines to be properly pruned, and to be got in readiness for starting into growth at any time when required. Give some manure-water to pot Vines that are swelling fruit, and keep them in a brisk moist temperature; 65°, with a dry atmosphere and a little air, are necessary for such as are in bloom. Syringe daily Peaches and Nectarines that have set their fruit, and attend to disbudding and watering, whether the plants are in pots or borders. Keep Figs in pots in a bottom-heat of from 75° to 80°; if maintained by means of fermenting material so much the better. Syringe daily, and supply water moderately. Keep those for late work in sheds or turned on their sides under stages, quite dry. Prepare hot-beds for Cucumbers, placing a little mound of good soil in the middle of the bed over the manure, and letting it rise to within 6 inches of the glass; one mound under each light is sufficient; shift seedling Cucumbers into larger pots, and a day or two afterwards pinch out the top of the leading shoot. Maintain a night temperature of 70° both in pits and frames, both for Cucumbers and newly-planted-out Melons. Keep up a succession of Strawberry plants; early Peach-houses or Vineries will be good positions for the earliest batch; succession fruit-houses for the next earliest crop, and frames for a late supply. Mushroom-beds, if at a temperature of 60°, may now be spawned. Continue the forcing of Asparagus, Seakale, and salading. Sow some seeds of vegetables for very early crops on slight hot-beds.

Kitchen Garden.—Continue to get into moderate heat in suc-

cession, strong plants of Asparagus; let the bottom-heat be moderate and genial, in order to give it plenty of time to put forth strong robust buds and shoots. Regulate the interior of the frame or pit by methodical airing. If the Asparagus is intended to be of a good flavour and eatable, allow it to colour well, by means of sun and air. Cover the roots lightly at first, then put on three or four inches of well-decayed tan, leaf-mould, or light earth. Water early in the afternoon with tepid water, and shut up and keep the frames dark by litter and mats if intended to be bleached white. No glass need be used; shutters will do for cover, or it may be placed in a cellar or Mushroom-shed. Keep a sharp eye on Broccoli that is coming on, and protect against frost by doubling the leaves down. Put a wisp of short straw over the heads. Of Broad Beans plant this month a full general crop, such as Dwarf Gem, Marshall's Dwarf, Early Long-pod, Broad Windsor, or any other good variety. Surface-stir on fine days, and dredge with dry dust against severe frosty nights. Those raised in frames and houses may be hardened off and transplanted in warm borders. Draw some earth to those above ground. Surface-stir and make up all gaps and deficiencies amongst Cabbages. Make another planting from reserved transplanted beds, and sow a small quantity in pans or on a warm border. Prick out those sown last month into shallow boxes as soon as they can be handled. Place in shelter, harden off gradually, and prick on warm borders as soon as the season permits. For real usefulness, the small sweet kinds are the most profitable and best appreciated; large, coarse kinds being only fit for cattle. Sow some Red Cabbage towards the end of the month. Sow small portions of Cauliflowers in succession, prick out those up in boxes and pans, and surface-stir. Plant out now some of the strongest autumn-sown plants that have been nursed and hardened in pots or frames on to warm borders. Surface-stir, clear dead leaves, and harden off succession plants. Those nursed under hand-lights, encourage by surface-stirrings, drawing up all round a little earth in order to raise the glasses and form a basin in the centre for the application of manure-water. Early varieties of Carrots, such as Horn and Dutch, sow on well-prepared, healthy, warm borders, in drills; and drill Radishes thinly between them for the last time this season. Shelter with straw or evergreen boughs for a time. Choose dry weather for applying earth to bleach late crops of Celery. Sow a pinch in gentle heat, and prick out early, into shallow boxes or pans, that sown last month to grow on in succession in frames, for early spring use. Sow Capsicums and Chillies in strong heat, and prick off as soon as up, an inch apart, in pots. Chervil.—Sow curled sort in small quantities in warm corners. Chives.—Divide the roots, and transplant them, about 9 inches apart. Lettuce.—Make good all winter crop blanks, and plant out in succession strong plants. Prick off and protect with dry dust small seedlings. Sow in gentle heat, and put a pinch on a healthy warm border, of summer Cos and Cabbage kinds. Beware of birds and mice. Dill and Fennel.—Sow some seeds of these towards the end of the month. Onions.—Transplant the autumn-sown on well-prepared ground, a foot apart, row from row, and 6 inches in the row, in order to have every other one pulled for early use. Sow in a box or frame, on a slight heat, Spanish, Tripoli, or any favourite variety, in order to have strong plants ready to put out the end of March or beginning of April. Sow thickly on a warm border and protect with a little straw the two-bladed union, for early drawing and "bulbing;" what is left will be of a beautiful size, shape, and colour for pickling. Plant out Potato Onions on firm ground; if on loose soil they are apt to canker, mildew, and rot. This also holds good in the case of Shallots, which should now, also, be planted above ground, that is, just pressed into firm soil. Garlic, also, plant now. Remove all old-keeping Onions into the coldest, draughty, dry place that can be found, in order to subdue growth and prevent exhaustion. Potatoes now growing in pits, frames, or houses, under hoops, or other shelter, should have plenty of air to maintain sturdiness. Surface-stir those lately planted. Earth with moderately moist, lightish, healthy soil. Be careful about the application of water; never apply it overhead, but only to the soil. Never water early Potatoes in the afternoon and shut them up directly, except you wish to produce disease, if, by any accident, they are caught in a shower when exposed to the air, leave them night air on and a space back and front of the lights for the moisture to have room to evaporate without settling on the foliage. A full crop of Potatoes should now be planted. Let them consist of early and middle early kinds, which have a better chance of escaping disease than late sorts. Sow some Tomatoes on hot-beds, or propagate them by means of cuttings; prick out, pot off into stiffish poor soil, and harden off in due season, those intended for out-of-doors. Sow the best curled Parsley in drills, 1 foot apart. Weed out, from old beds or rows intended for seed, every plant that is not fully up to the mark as regards curled quality. Sow now some of the best varieties of Peas of second crop kinds, both dwarf and tall, such as Advancer, Auvergne, Green

Marrow, Climax, Harrison's Glory, Perfection, Napoleon, Nonpareil, Veitch's Perfection, Champion of England, the Prince, &c. Shelter with sticks and a few green boughs in the cold windward side, and dredge with dry dust, on dry evenings, against frost, those now up and growing. Peas should now be sown on open quarters, 10, 12, or 14 feet apart, thus inducing them to produce as much again as thickly-sown crops. Planted or sown between the rows may be drills of early Turnips, Spinach, and Radishes, spring-sown young Cabbage, Cauliflowers, early Potatoes, &c., all of which will be off and out of the way by midsummer, or sooner, rendering the ground available for Celery. After the Peas are cleared off, the space will be available for successions of Lettuce and Endive, young Coleworts, &c., all of which will be again off before the soil is required for earthing the Celery. Sow the first portion of Brussels Sprouts, Borecole, Buda Kale, after the middle of the month, in order to have some strong plants, fit to produce a heavy autumn and winter crop. Early varieties of Turnips, such as American Pink, Stone, Dutch, &c., should now be sown on well-prepared warm borders. Sow Spinach in single drills between Peas, and stir the surface soil about winter Spinach, which must be kept in a growing condition.

Specimen and Exhibition Plants.—Large Heaths, Chorozemas, Boronias, Dracophyllums, Genetyllises, Aphelandras, and similar plants should now be staked and tied into such shapes as it may be desired they should assume. A position near the glass is best, and especially one in which all sides of the plants may be subjected to an equal degree of light. In training plants of Dracophyllum, unless the long shoots are twined round the base of the plant, and only the points of last year's shoots allowed to grow upwards, a symmetrical or handsomely-grown specimen cannot be obtained. Many train the old wood of these plants over a trellis and allow the blooming points to project outwards a little, but the result of such a method is not satisfactory. From specimen Heaths, whose roots were reduced last summer when re-potted, no flowers can be expected during the ensuing summer, and any blossoms that do appear should be removed so as to promote free growth. Heaths, whose roots are so reduced, generally take two years to recover their former vigour, but, the second year after the operation, if they have been judiciously treated, a magnificent amount of bloom may be expected. Show and fancy Pelargoniums keep in a cool well-aired house and in close proximity to the glass. If the stages do not permit of them being near enough to the glass, raise them upon inverted pots, blocks of wood, bricks, &c. Although wirework for training purposes was refixed when the plants were cut back, no attempt should be made to tie down any of the shoots yet; on the contrary, a slow and stocky growth should be encouraged, which is the most productive of flowers; no fire-heat should, therefore, be employed for these plants in winter beyond what is necessary to expel frost. If required for early shows, a little fire-heat may be applied after February. Allamandas may be re-potted, cut well back, and allowed to break freely; they should be kept moderately dry for a time. Dipladenias will now be producing their young wood, which should be trained to fine string run across the rafters inside the stove. If the pots in which they grow are plunged, or even partially so, in a moderate bottom-heat, it greatly assists their growth; and, if the wood is produced early without check, and by free exposure to light, made firm, abundance of flowers will, doubtless, be the result. If not already done bring down the shoots of Clerodendron Balfourii and splendens, and train them around the trellises fixed on the pots. As Clerodendrons produce their flowers from the old wood, none of it should be removed at present; but, after they have done blooming, they may be pruned, re-potted, and encouraged by bottom-heat and a high temperature, to produce their young growths, which should be trained along the inside of the glass on threads, as recommended for Dipladenias, with the exception of the difference of season, viz., Dipladenias from the middle of January until they begin to come into bloom, and Clerodendrons from the time they have done blooming until they form and thoroughly mature their young shoots, which will be the blooming ones of next season. Stephanotises may now be unfastened from the cords on which they have been supported and trained around their trellises; if required early, raise the temperature of the house, or transfer the specimens to a warm moist stove. A too high temperature in winter is, however, more injurious than beneficial, as it deprives them of their proper rest; but it must not be allowed to fall under 55°.

THE *Journal of the Society of Arts* says: It may be new to most readers that a bronze halfpenny is exactly an inch broad, and therefore gives us a very convenient measure. Laid on an Ordnance map of the inch scale the halfpenny covers just 500 acres. Now, also, that the third of an ounce is a postal unit, it is well to remember, that a penny is precisely that weight.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but

THE ART ITSELF IS NATURE."—*Shakespeare.*

BIRDS IN GARDENS.

By T. BAINES, Southgate.

THOSE who recommend the indiscriminate destruction of small birds can never have taken the trouble to study the habits of the different species that inhabit our island—a difference, so far as the gardener is concerned, that is not always determinable by the individual species of bird, for some will attack particular crops in one part of the kingdom that escape injury in others. There is, also, a difference in the stage of growth in which a particular crop may be when it is attacked by some species of birds in different localities. Sparrows, for instance, in some parts of the country, begin their work of destruction upon Peas the moment they appear above ground, nipping the points of the shoots; but, if kept from them until the Peas get fairly above ground, no further molestation will be experienced until the crop is ready for gathering; in other places, they never cease their attacks from the time the Peas are up until they are removed from the ground. Here, with us, they keep at them all through the season, nipping out the leading points, and, as soon as the flowers are formed, picking them out from the leaves with which they are enclosed; and, if means were not taken to prevent them, we should never have a Pea to gather. In the Cheshire market-gardens, and in the neighbourhood of Manchester, they will frequently make an attack on the Onion crop as soon as it appears above ground, pulling the young plants up, simply through, to all appearance, a disposition to do mischief, for they leave the young plant, seed and all, lying on the ground entire, while in no other part of the country have I seen them molest Onions. Here, winter Lettuces are often attacked about the beginning of March, and, if not made unpalatable by a dressing of soot, they destroy the whole crop. Crocuses they never allow to open, as they attack the flowers as soon as they show colour, pulling the petals to pieces so as to get at the pollen, for which they seem to have a particular liking. Gooseberry and Currant buds suffer as much in this neighbourhood from sparrows as they do in some localities from bullfinches. Cotton, such as is used for dip-candlewicks, ravelled out singly, and strung loosely so as to be moved by the wind over anything they molest, I have always found sufficient to scarce them off; even after the Peas are sticked, I find it necessary to use this. Chaffinches and greenfinches take indiscriminately the seeds of all the Brassica family. At one time I used netting to protect these seeds until they were sufficiently large to be out of danger, but it is a troublesome job, as nothing you can do will deter them, and, if there is a possibility of getting under the net or through it, you generally have the mortification of seeing your young crop destroyed. I have, for a good many years, coated the whole of the seeds of this description with red lead, and never since have I lost a crop. I have heard, however, that some, who have tried this, have found it to be ineffectual, but I suspect that the lead was not properly applied. The seed should be damped, but not made too wet, and thoroughly coated with dry powdered lead, which should be allowed to dry on before the seed is sown, when it will stick so fast that, if any of the seed lies on the surface of the ground, the rain will not wash it off. In this matter of small birds, gardeners are placed in a somewhat difficult position. Taken as a class, I maintain that they are about the last who would be guilty of wanton cruelty; neither are they devoid of a correct knowledge as to the whole or partial uses of some species of the feathered race in the garden, as some writers have insinuated. If a gardener admits that he destroys sparrows and finches, or kills a few blackbirds or other songsters, when swarming by hundreds upon fruit crops, for the saving of which he is held responsible, he is denounced as a monster, who has not the common sense to distinguish between his friends and

his foes. Those who decry the destruction of all birds, on the score that every species does more good than harm in a garden, very much weaken their case by the misstatements they make. They tell us that the fruit-buds attacked by the birds contained the larvæ of insects, which would have destroyed the whole crop had it not been for the birds. I have frequently proved the fallacy of this, by netting the half of a tree and leaving the other half unprotected; the difference being that, in the case of bush Currants and Gooseberries so treated, the protected halves of the trees bore full crops, whilst, on the portions left unprotected, there was not half a dozen fruit. We are also told of the thousands of aphides that sparrows destroy, and of the condition in which our bush fruits would be were it not for them. I am aware that sparrows will sometimes eat a few aphides, and so will a dog eat grass; but I never heard of any one's hay-rick being smaller for the quantity of grass his dogs eat, no matter how many he kept; and the quantity of aphides that sparrows will eat stands in about the same proportion. If there is any time in which these birds will destroy insects, it is when feeding their young. I have frequently killed and opened the crops of young sparrows at different ages before they left the nest; but I never found a single aphid in them. Their food is generally made up of small green seeds, the young leaves of Peas, and soft broken corn that had unmistakably passed through the stomach of horses. I have also confined sparrows and finches in a room, leaving them small caterpillars and aphides, but nothing in the shape of corn or seed, and they never touched a single grub; and, at the end of twenty-four hours, the aphides remained on the Currant-leaves as they were put in. I removed these and substituted some corn, which they devoured as soon as left to themselves. Hard-billed birds will no more subsist upon insects, than soft-billed birds will live upon grain. The Act for the Preservation of Small Birds bore evidence of ignorance on the subject on the part of those who drew it up; they managed to leave unprotected some of the most harmless, as well as most useful, of all birds that we possess. The house sparrow and the finches, are all but an unmixed evil in gardens; all the small soft-billed birds should be encouraged as much as possible, the larger species—blackbirds and thrushes—notwithstanding the quantities of snails, and other pests, they destroy, require to be kept within reasonable limits, or the production of fruit, where it is required in quantities, without incurring expense in nets, and other protecting material, equal to the value of the fruit, is an impossibility. Those who advocate the protection of all small birds forget that kestrels, merlins, sparrow-hawks, jays, and magpies—Nature's instruments for maintaining the wanted balance in the smaller feathered tribes—are all but exterminated; hence, the necessity for reasonable reduction in their numbers by other means.

Mutilation of a Favourite Myrtle.—It is not often the judge of a small debt court has to assert a sentimental grievance. Less seldom does he allow any but purely commercial considerations to influence his decision. A case, however, came before Sheriff Hallard, of Edinburgh, a day or two ago, in which he allowed costs to one of the parties to a suit by way of *solatium* for wounded feelings. Nearly fifty years ago a sprig of Myrtle selected from a bridal bouquet was planted in the garden of a house in Duncan Street, Newington. In time, the house and "pertinents thereto belonging," became the property of the bride's daughter, by whom they were let to a clergyman named Wemyss. Before entering into possession, Mr. Wemyss was strictly enjoined not to harm the Myrtle, now become a stately plant. But the reverend gentleman, finding it interfered with other plants in the conservatory, which had been erected for its own special protection, ruthlessly pruned and mutilated it. Thereupon he had to answer an action against him for £10. In court it was proved by a competent person that the intrinsic worth of the tree was £2 10s., and the sheriff was thus called on to decide between the sentimental and botanical side of the dispute. This difficult task was performed with satisfaction to all concerned, except, perhaps, to the defendant. Declaring his opinion that, "in the rough alembic of lawyers, feelings which went in at one side came out at the other in pounds, shillings, and pence," he allowed the plaintiff £5 5s., with £2 2s. as costs and the ordinary court expenses. We are happy to learn from a local journal that the Myrtle itself has not been "irretrievably damaged." There is now hope that the reverend woodman will spare the tree for the future.

NOTES OF THE WEEK.

— MR. MARNOCK has been consulted by the corporation of Sheffield as to the laying out of the park given to that town by the late Miss Harrison. Mr. Marnock, it will be remembered by many, formed the Botanic Gardens in Sheffield many years ago, and it is, like the garden in the Regent's Park, very tastefully laid out.

— THERE are now in bloom in Mr. Barr's bulb grounds *Galanthus plicatus* and *G. Imperati*, the latter a great advance on *plicatus*. It has the same broad foliage as that *Snowdrop*, but the flowers are twice as large as those of *plicatus*. It may, therefore, be imagined what a gain it will prove for our gardens.

— FOR the last five or six years, the Society of Industrial Sciences at Lyons have been carefully investigating the capabilities of the common Broom (*Sarothamnus scoparius*) as a textile plant. From a recent report, we learn that the fibre makes an excellent coarse cloth, suitable for domestic purposes, and especially as a packing material, and that a more elaborate preparation of it yields a material not inferior to the best Hemp in strength and fineness.

— MESSRS. SUTTON & SONS, of Reading, have just issued a "Geological Map of England and Wales, whereby a farmer, or landowner, may be enabled to ascertain the geological strata in which his farm is situate." The map, of which we have received a copy, appears to be very carefully projected, and is presented to purchasers of Messrs. Suttons' "Farmer's Year Book and Grazier's Manual." It will, also, doubtless, prove useful to gardeners.

— THE recently appointed Committee on Planting and Decorating the Grounds for the Great Centennial Exhibition, at Philadelphia, is composed of the following well-known and perfectly competent members:—Wm. Saunders, R. M. Copeland, Frederick Law Olmsted, Josiah Hoopes, and Charles U. Miller. From what we saw of the work of some of these gentlemen in American parks and public gardens, we look forward to something very good, indeed, at Philadelphia in 1876.

— As an instance of "dichroism," or diversity of colour in the flowers of the same plant, M. Carrière mentions a case which has recently come under his observation. For some years past he has grown some specimens of *Gynierium elegans*, of the variety which bears broad loose panicles, and which he has characterised by the popular name of "Chapeau chinois," or the "Chinaman's Hat." Hitherto, these have always borne their customary bright yellow silken panicles; but, last year, M. Carrière was surprised to observe that one of the plants bore two panicles, one of which was of the usual yellow colour, while the other was rose-coloured. M. Carrière's long experience does not supply him with a solution of this anomaly, an explanation of which he asks for by a laconic "Why?"

— SPEAKING of the Royal Horticultural Gardens, at South Kensington, the London Correspondent of the *Manchester Guardian* says the ticket-holders are nursing their wrath at the prospect of another year's overflow into their sacred precincts of the visitors of the International Exhibition, which has now taken root as a London perennial. The gardens, as such, are a very dismal failure, it must be confessed. The *coup d'œil* is that of a cemetery vainly trying to look cheerful. Stained brickwork, masonry, and stucco-tazzas reign supreme; turf, shrubs, and flowers are at the most genial season quite subordinate features; but it is a safe and convenient place for the subscribers' children, with their *bonnes* and governesses. To still the contention, some say, "Try a friendly Chancery suit." Others say, "Look at the great Alabama case; try arbitration." So the matter stands.

— At a meeting, the other day, of the Leeds Town Council, Mr. Alderman Shepherd moved—"That the council award the premiums for designs for laying out Roundhay Park estate as follows:—1st prize, 200 guineas, Mr. G. Corson, architect, Leeds; 2nd, 100 guineas, Messrs. G. Hornblower & Son, Liverpool; 3rd, 50 guineas, Messrs. Perkin & Sons, Leeds." Mr. Alderman Kelsall seconded the motion, which was adopted. Mr. Alderman Shepherd then moved the confirmation of the minutes of the corporate property committee. Mr. Smith, however, objected to their confirmation. He declared that the purchase of the park was a mistake, and that a great deal too much money had already been spent upon it. He was satisfied that if the purchase of the park estate were proposed now—when the people had come to their senses—it would not be agreed to. As much money had been thrown away on the park as would buy four recreation grounds in various parts of the borough.—(A voice: Ten.)—Mr. Scarr also opposed the confirmation of the proceedings of the committee, on the ground that he disapproved altogether of the principle of obtaining prize plans for the laying out of the park. After some further discussion, the resolution was carried. It was stated in the course of the discussion that to carry out Mr. Corson's plan would render necessary an expenditure of £30,699 for roads and paths inside the park, and

£36,829 for roads and sewerage works outside the park, a total of £67,258.

— IN the month of January, 1873, the value of Potatoes imported was £282,303, and in the same month this year only £83,329.

— ON the night of the 10th-11th of February, the thermometer at Berne fell to 8 degrees below zero of Fahrenheit.

— WE are to have a Japanese garden at Alexandra Park. Some Japanese workmen are already employed in erecting the houses.

— MR. BURBIDGE's book on cool Orchids has just been published by Mr. Hardwicke; it is likely to prove very useful to cultivators of this beautiful class of plants, and is embellished by four coloured plates and a number of useful wood engravings.

— UPWARDS of 3,000 dozen of Broccoli are weekly consigned from Cornwall to the London markets for sale, and, during the last four months, it is computed that 50,000 dozen heads of Cornish Broccoli have been received, sold, and consumed in the metropolis as Cauliflower.

— THE *Irish Gardeners' Record*, which seems growing in interest and prosperity, appears in a much better dress this week than usual, and it is printed from new and excellent type. A country so well adapted for gardening as Ireland is can scarcely fail to benefit by a journal specially devoted to this and allied subjects.

— AT the approaching great International Horticultural Exhibition, which will be held at Florence from the 11th to the 25th of next May, a novelty will be introduced in the offering of six prizes for the most artistic and faithful representations of flowers, fruits, and plants, executed in (1) pencil-drawing, (2) photographs, (3) water-colours, (4) chromolithographs, (5) painting in distemper, and (6) oil-painting.

— UNDER the name of "*Jaquinia smaragdina*," M. André describes, in a recent number of the *Illustration Horticole*, a plant grown in M. Linden's nursery at Brussels, with blackish-green foliage, and large, handsome, emerald-green, rosaceous flowers. M. André speaks of it as a most effective plant, possessing a more modest beauty than even that of the Violet ("*une beauté plus modeste encore que celle de la Violette*").

— WE have received from Mr. Wortham, of Cannes, a photograph of *Chamarops excelsa*, which shows how well the climate of that part of France suits this Palm tree. It is about twenty years of age; its height to the extreme ends of the leaves is 12 feet 10 inches; circumference of trunk, 2 feet 8 inches; and the number of seeds which it produces annually is about 25,000. This Palm grows out of doors in this country, even as far north as York, but we have never heard of its bearing seeds in England.

— AT a sale of Orchids, which took place at Stevens' the other day, lots of the rare and beautiful *Dendrobium Jamesianum*, each consisting of two strong plants, fetched from 20s. to 50s. per lot. *Cœlogyne Reichenbachiana*, described as decidedly the best of the *Pleione* group of that genus, realised from 10s. to 20s. a plant, while lots of three and four bulbs of *Odontoglossum Roezlii* fetched from two to five guineas each. Altogether the sale, which was a somewhat miscellaneous one, realised about £700 for 502 lots.

— M. GODRON, Professor of Botany at Nancy, has recently published a pamphlet "On the Origin of our Cultivated Pears and their numerous varieties," in which he contends that they are derived, not, as has been commonly supposed, from the European wild Pear (*Pirus communis*), but, through long-continued hybridisation, from an original Asiatic type, introduced into Europe at a remote period. M. Godron's arguments in support of this view are very ingenious, but are given at such length that we must leave our readers to form their own deductions from a perusal of his interesting treatise.

— THE current number of the *Revue Horticole* contains a coloured plate of the fruit and foliage of a new kind of *Diospyros*, which M. Carrière has named "*D. Mazeli*." It appears to be quite distinct from *D. costata*, which attracted so much attention two or three years since. The fruit is about as large as a medium-sized Apple, of a depressed spherical shape, and, when fully ripe, of a fine deep orange colour. The interior is filled with a very soft pulp, the flavour of which is said to resemble that of Apricot marmalade. The plant was received, amongst others, from Japan, in 1866, by M. Mazel, of Anduze (Gard), after whom it has been named.

— M. H. J. VAN HULLE, writes to us as follows:—"On the night of the 12th-13th inst., the neighbourhood of Gand was visited by a sharp frost of—10° Cent. (= 13° Fahr.). This will prove most fortunate for our fruit-crops; for, as the Peaches and Apricots on south walls were commencing to open their buds, and even those of the Pear trees were beginning to swell, we should have had little chance of fruit this year, had not this timely frost supervened. In consequence of the seasonable check which it has given to vegetation, we have now some hope of a good harvest; at present, at least, appearances are most favourable in every way."

THE FLOWER GARDEN.

HARDY KINDS OF HIBISCUS.

THE genus *Hibiscus*—one of the richest and most varied in species of the whole vegetable kingdom—has contributed some of the finest ornaments of our hothouses, conservatories, and gardens. The greater number of the species are natives of tropical regions, a few only being found in temperate latitudes, and, consequently, few are available for open-air culture in this country. One of the finest of these, *H. speciosus*, is the subject of our illustration. This plant is a native of South Carolina, whence it was introduced in 1778 by J. Fothergill. It is an herbaceous perennial, growing from 2 to 8 or 9 feet high, with numerous branches, and smooth, palmate, five-parted leaves, the divisions of which are long, narrow, and pointed. The flowers, which appear in August and September, are very large, spreading, and of a fine scarlet colour, and, under favourable conditions, are produced in such abundance that the plant is quite covered with them, and presents a splendid appearance. The following is the mode of treatment pursued by M. Dommage, of Montrouge, whose garden some time since contained remarkably fine specimens of this plant:—During the winter he kept the plants in a temperate house, and, in February, transferred them to a warm house, in which they remained until June. By this means vegetation was vigorously pushed on. About the middle of June, he planted them out in the open air, in a warm and sheltered position. By this course of treatment, M. Dommage obtained specimens over 9 feet high, with a dense bushy habit, and producing flowers in great profusion for two months. The soil proper for this species is a compost of free loam and heath-soil. The plants should be kept dry during the winter, but require a copious supply of water during the season of growth.

In addition to the foregoing species, we may here mention a few other hardy kinds of *Hibiscus*, viz., *H. militaris*; 3 to 4 feet high; flowers, purplish-rose, with a darker centre. Native of Louisiana, Pennsylvania, and Carolina. *H. Moscheutos*; 3 to 5 feet high; flowers, light rose-colour, sometimes nearly white, with a crimson centre, as large as those of the common Hollyhock. New York to Carolina, in swamps and salt marshes. *H. palustris*; 3 to 5 feet high; flowers, large, purple, on long axillary stalks. This species has often been confounded with *H. Moscheutos*, but is quite distinct. Canada to Virginia. *H. roseus*; 4 to 6 ft. high; flowers, showy rose-colour, 4 inches across. A very handsome plant. France, on the banks of the Adour. We shall conclude our list with the dwarf annual, *H.*

Trionum, also known as the Bladder Ketmia. This plant grows from 6 to 18 inches high, and bears (from June to September) cream-coloured flowers with a dark purple centre; the calyx is membranaceous, inflated or bladdery, and full of nerves. Italy, Carniola, and New Zealand. All the species here mentioned may be propagated either from seed or by division. W. M.

NEW VARIETIES OF CANNA.

In a recent number of the *Journal de la Société centrale d'Horticulture de France*, M. Nardy, of Hyères, describes the following as the best of the new varieties of *Canna* raised since 1867:—

Compactum (Nardy).—Stems, numerous, from 4 feet 10 inches to 6 feet high; leaves, broad, light green; flowers, numerous, yellow dotted with red.

Daniel Hooibrenk (J. Sisley).—Stem, about 6 feet high; leaves, lance-shaped, green; flowers, numerous, large, salmon-coloured.

Edward Morren (J. Sisley).—Stems, about 5 feet high; leaves, lance-shaped, green; flowers, in numerous spikes, large, yellow dotted with bright nasturtium red.

Gloire de Lyon (Crozy).—Stems, numerous, about 6½ feet high; leaves, lance-shaped, purple; flowers, large, salmon-coloured.

Gaboniensis (Crozy).—Stems, very numerous, from 6 to 6½ feet high; leaves, lance-shaped, glaucous green; flowers, very numerous, rosy-carmine.

Henry Vilmorin (Huber & Co., Hyères).—Stems, numerous and strong, from 4 feet 10 inches to 6½ feet high; leaves, broad, deep green, very firm; flowers, large, of a nasturtium orange-colour. One of the most ornamental varieties in foliage.

Jacques Plantier (Nardy).—Stems, from 5½ to 6½ feet high; leaves, lance-shaped, purplish-green; flowers, unusually large, salmon-coloured.

Jean Bart (Denis).—Stems, thick, from 4 feet 10 inches to 6 feet high; leaves, lance-shaped, bronzy-green; flowers, very large, of a wine-red colour.

Jean Sisley (Huber & Co., Hyères).—Stems, numerous and thick, over 9½ feet high; leaves, large, light green; flowers, bright red.

Jean Vandael (J. Sisley).

—Stems, about 4 feet 10 inches high; leaves, lance-shaped, green; flowers, numerous, large, of a wine-red colour.

Madame Cellier (Chrétien).—Stems, about 4 feet 10 inches high; leaves, lance-shaped, light green; flowers in numerous spikes, large, cherry-red. A seedling of *C. Bihorelii*.

Madame Schmitt (Nardy).—Stems, numerous, from 6 to 6½ feet high; leaves, lance-shaped, green; flowers, large, numerous, cherry-red.

Prince Imperial (Chrétien).—Stems, numerous, about 3 feet 3 inches high; leaves, numerous, light green; flowers in many spikes, of a bright red colour. A seedling of *C. Bihorelii*.

Tricolor (Henderson).—Stems, numerous, from 2 feet 4 inches to 2 feet 8 inches high; leaves, numerous, green, striped with white and a little rose-colour; flowers, bright red.

A Hardy Hibiscus (*Hibiscus speciosus*).

Pancratium maritimum.—In the "Life of Mrs. Somerville," p. 308, it is stated that "at Viareggio the loose sand is drifted by the wind into low hillocks, and bound together by coarse Grass, thickly coated with silex. Among this and other plants a lovely Amaryllis, the *Pancratium maritimum*, with a sweet and powerful perfume, springs up. We often tried to get the bulb, but it lay too deep under the sand." Is *P. maritimum* the same as *P. fragrans*?—ALPHA. [*Pancratium maritimum* and *illyricum* are the only kinds found in the south of Europe, and they are tolerably distinct and hardy when planted in a warm border. The *Pancratium fragrans* of Loddige's "Botanical Cabinet," plate 834, is a tender West Indian kind, and the same as *Hymenocallis fragrans* of Herbert's *Amaryllidaceæ*. All of them are very fragrant, particularly in the evening.—ED.]

The best races of China Asters.—I have grown a complete collection of Asters to ascertain the merits of recent introductions, and have discarded the Humboldt, the Shakespeare, and the Bismarck Sections, as having no fixed character, and, therefore, worthless for English gardens. For large beds, the Hamburg Prize, *Pæony Perfection*, the *Victoria*, the *Cockade*, and the *Hedgehog*, are the most desirable. For medium-sized beds, ribbons, &c., the *Dwarf Chrysanthemum*, the *Dwarf Victoria*, and the *Schiller Dwarf Pyramidal* are the finest, being compact, and of even growth, bearing their flowers conspicuously above the foliage. To cut for bouquets, the *Imbriqué Pompon*, and the *Dwarf Bouquet Elegantissima*, are of the most exquisite colours, and perfect models in shape, ranging from the most miniature to the size of a *Pompon Chrysanthemum*. For a continuous succession of bloom, seed should be sown at intervals, from the beginning of March to the end of May; the first sowings under glass, the latter sowings may be made where the plants are intended to flower.—P. BARR.

Zauschneria Californica.—This, though now seldom seen in our flower gardens, is, nevertheless, worth attention under certain circumstances. The year before last with us it was too leafy and late in coming into flower; but having been left in the ground through the winter, it pushed freely in the spring, and threw up ground shoots or suckers all round. It soon covered the bed in which it was planted, and was in full flower early in August. Though unsuited for early bloom, and the colour (an orange-scarlet) not so striking as that of many other bedding plants, still those who appreciate variety of habit as well as colour, will find a distinctness of character in a bed of this plant, when in good condition, that must recommend it to their favourable notice. Its position in the flower garden would seem to be some intermediate place between beds which, having stronger colours, are better adapted for contrast, and more effective at a distance, or, perhaps, as a detached bed, which comes in for a close inspection, and to show off the flowers to the best advantage. Gales of wind, which play sad havoc with many other plants in gardens, leave this unharmed.—E., *Thetford*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Dwarf Ageratums.—These are splendid bedding plants, blooming continuously till destroyed by frost. Cultivated in pots, all the varieties are useful under glass. To cut for furnishing vases, the flowers are most valuable, the blue changing to a rich mauve by candle light. The *Tom Thumb* and *Imperial Dwarf* varieties are most valuable additions to our bedding plants.—P. B.

Saxifraga Burseriana.—I have a charming little Saxifrage, one of the prettiest with which I am acquainted, belonging to the *Juniperina* section, and which is now covered with large pure white flowers. It is *S. Burseriana*. I see it spoken of as being in bloom with Mr. Atkins, who had it from here last season. It comes from Switzerland.—T. S. WARE, *Hale Farm, Tottenham*.

Plants in Bloom.—I have in flower a curious little Cape bulb, viz., *Hesaea spiralis* (white), *Primula erosa*, *Primula verticillata*, *Ruta albiflora*, *Schizostylis coccinea* in a frame, as well as abundance of *Cyclamens*. *C. coum album* is now exceedingly pretty. Out-of-doors there are but few things in flower; among the most notable are *Crocus biflorus*, *C. Aucheri*, *Primula altaica*, *Hepaticas*, *Sisyrinchium grandiflorum*, and one or two of the *Megaseas*.—A. J. PERRY.

Opuntia Rafinesquiana.—In a recent number of the *Illustration Horticole*, M. E. André disputes the claim of this plant to be considered a distinct species, and further reduces eighteen hitherto-received species and sub-species of North American *Opuntias* to mere varieties of *O. vulgaris*, resulting from differences of soil, climate, altitude, &c. As a corroboration of his opinion, he states that, some time since, M. Verlot planted, in the garden of the Muséum, a specimen of *O. vulgaris* by the side of one of *O. Rafinesquiana*, and that the former has since lost its tropical aspect, and assumed, in a marked degree, the hardy northern appearance, the almost creeping habit, and the wrinkled joints of the latter.

Calochortus Gunnisonii.—The genus *Calochortus* comprises, as is well known, some of the gayest bulbs of the Californian flora, and all the species have, from their earliest introduction, been highly prized. The *C. Gunnisonii* appears to be closely allied to *C. venustus* and *C. Nuttallii*, and has, in fact, been considered as synonymous with the latter species. Further examination of flowering specimens is necessary to determine these points. The flowers when fully expanded are from 2 to 3 inches across. The plant grows in Utah, where the bulbs are said to occur at a depth of from 6 to 10 inches. Seedlings are not difficult to raise, but as they do not attain any size the first season of their growth, the amateur must be cautioned against allowing the soil of the pot containing them to become dust dry after the annual growth is completed, and the foliage withered, which would result in the destruction of the bulbils. On the other hand, an excess of moisture is equally to be avoided.—T.

THE INDOOR GARDEN.

ADIANTUM FORMOSUM.

THIS, when well-grown, is one of the most distinct, and, as its specific name implies, beautiful of Ferns. It grows well in a warm greenhouse and is quite at home in a close Wardian case, but, if large specimens of it are required for exhibition, they may be quickly obtained by keeping them either in an ordinary plant-stove or tropical Fernery, where the atmosphere is warm and charged with humidity. Good strong plants of this species produce fronds from 2 to 2½ feet in length, and about a third more in breadth. The fronds are of a fresh green colour and are well adapted either for grouping along with choice exotics in bouquets and wreaths, or for using along with flowers in the drawing-room vase. Our illustration, taken from an original sketch, shows the general habit of the plant and the form of its drooping fronds. Like all Maiden-hair Ferns, it grows rapidly in a fresh open fibrous compost of turfy peat, sand, and about one-fifth of good fibrous loam—that from an

Adiantum formosum.

upland pasture or from the face of sandstone rocks being best. The pot in which it is grown must be well drained, and the plant requires liberal supplies of tepid water at the root during the summer months.

B.

TREE-FERNS.

(Continued from p. 9.)

Alsophila.

THE species of this genus, to which I shall allude in the following remarks, are all extremely beautiful. They belong to the *Cyatheaceæ*, and, indeed, are very nearly allied to the genus *Cyathea*, the chief point of distinction being that the sori in *Cyathea* are enclosed in a scaly cup-shaped involucre, while those of *Alsophila* are quite naked; the species belonging to *Alsophila* are widely distributed over the tropical and temperate regions of the globe, although no member of the genus belongs to our European flora. As a genus, *Alsophila* is characterised by its arborescent stems, by its large bi-tripinnatifid fronds, simple or forked free veins, and naked sori, which characters, apart from the arborescent growth, leave few distinguishing points between *Alsophila* and *Polypodium*, to which genus, indeed, early authors usually assigned it. The species from the East Indies (few of which, however, are, unfortunately, in cultivation) and also those from South America and the West Indian Islands have mostly slender stems, which are developed somewhat rapidly, and are, more or less profusely, armed with stout sharp spines; whilst those from more temperate

regions have usually much stouter stems, which they build up much more slowly, and have the spines reduced to mere small rough points. In a cultural point of view, the tropical kinds require an abundant supply of both heat and moisture, and although I strongly advocate the use of the syringe for moistening their stems, I consider the less it is brought into play on the fronds the better. As a compost for these plants, in a young state, I prefer using two-parts peat, one-part loam, and one of sand; but as they attain size, or, for re-potting old plants, peat and loam in equal parts will be found preferable. The drainage must always be in good working order, and over-potting must be avoided. It is my firm opinion that there are many sheltered glens throughout the country where several of the Australian kinds would thrive admirably in the open air, and I would strongly urge upon the fortunate possessors of such spots, the advisability of trying the experiment.

TEMPERATE HOUSE SPECIES.

A. AUSTRALIS.—This species, at one time thought to be rare, would seem to be found, at times, in tolerable abundance. When mature, its stems are said to attain a height of some 20 and even 30 feet, and to measure from 2 to 3 feet in circumference; the beautiful head of fronds which crowns its summit, extending from 10 to 13 feet from the centre. In this country, the stems rise from 3 to 10 feet in height; they are of various degrees of stoutness, and are easily recognised by the bases of the old fronds which clothe them, and which are thickly studded with short obtuse prickles; the fronds are somewhat ovate-lanceolate in outline, bipinnate; pinnules, linear-lanceolate and deeply pinnatifid, deep green on the upper side, paler below, the base of the stipes and crown of the plant being clothed with large dark chestnut-brown chaffy scales. Native of New South Wales, Tasmania, and other places.

A. EXCELSA.—Although a well-known plant in our Ferneries, this species would appear to be little understood, for, in very many instances, I find it grown under the name of *A. australis*, from which, however, it wholly differs. Others, again, call it *A. Cooperi*, whilst we have even seen the name of *Cyathea excelsa* made to do duty as one of its synonyms. The plant in question is a rapid grower, and forms a stem very quickly, for which reason it is not so well adapted, as some others, for those with whom space is an object, although few species, either in a young or mature state, can surpass it in beauty of outline. The fronds are broad and spreading, bipinnate; the stipes pale-coloured, slightly muricate, and, together with the crown of the plant, densely clothed with large light-coloured chaffy scales, intermixed with wool, which at once distinguish it from the previously-described species; indeed, in the absence of stems, these chaffy scales or hairs, which, almost invariably, are to be found clothing the crowns or base of the stipes of Tree-Ferns, form excellent characters by which to determine species, and should always accompany specimens intended for the herbarium. In Norfolk Island, *A. excelsa* is said to attain a height of from 40 to 50 and even 80 feet.

A. COOPERI.—In the form of herbarium specimens, this is, undoubtedly, difficult to separate from *A. excelsa*, but, in the shape of living plants, the two are distinct enough. *A. Cooperi*, as far as is known to me, produces a somewhat slender stem, and does not develop it so rapidly as *A. excelsa*; the fronds are bipinnate, the segments being pinnatifid, bright green on the upper side, inclining to glaucous beneath; the crown and stipes being clothed with dark brown chaffy scales, intermixed with hairs. It is a native of Queensland.

A. LEICHARDTIANA.—Amongst Tree-Ferns this is truly a gem. Its stem is very slender, attaining a height of 20 feet, or even more, the fronds forming a beautiful arched crown of plume-like leaves upon the apex; they are from 5 to 10 or 12 feet in length, bipinnate; the pinnules being deeply pinnatifid, and bright green in colour; the base of the stipes and the main rachis are furnished with numerous dark brown spines. It is a remarkable fact that, although this species is so thoroughly different from all others, it has no fewer than three names, having been called *A. Macarthuri*, by Sir W. Hooker; *A. Moorei*, by Mr. John Smith; and *A. Leichardtiana*, by Dr., now Baron, Müller, director of the Botanic Gardens, Melbourne. This beautiful species is a native of Queensland.

A. CAPENSIS.—This species is frequently included in the genus *Hemitelia*, being placed there on account of the scales,

which are scattered over the under-side of the pinnæ, presenting, somewhat, the appearance of the half-cup-shaped indusium peculiar to those plants. I have not been able, after repeated examinations, to convince myself that these scales have anything in common with an involucre, and so, in this enumeration, I retain it in the genus *Alsophila*. The stem attains a height of from 6 to 10 or 12 feet, is somewhat slender, hard, and black-looking; the fronds are tripinnate, from 3 to 4 or 5 feet in length, with the edges of the segments serrate; they are ovate-lanceolate in outline, and deep green in colour. A remarkable feature in this species is the production of abortive pinnæ upon the lower base of the stipes; these are short, much divided, and linear, and, as seen growing upon the plant, have the appearance of an epiphytal Filmy Fern, in a barren state; indeed, they were described by Kaulfuss under the name of *Trichomanes* (?) *cormophyllum*. It is a handsome plant; but, nevertheless, it is not found as a common inmate of our Ferneries. It is a native of mountain ravines in the country about the Cape of Good Hope.

STOVE SPECIES.

A. GLAUCA.—In this fine species we have one of the few East Indian Tree-Ferns which, at present, exist in our Fern-houses. The stem attains a considerable height, and bears a splendid crown of large arching fronds, which vary from 6 to 12 feet in length; they are bipinnate and coriaceous in texture; pinnules, deeply pinnatifid, the upper surface being bright shining green, the under-side glaucous; stipes and main rachis, muricate, the stipes and crown of the plant being furnished with a profusion of large white chaffy scales. Native of Penang, Java, and the Philippines.

A. GIGANTEA.—This would appear to be both widely distributed and extremely variable. When favourably situated and fully developed, it is said to attain a height of upwards of 50 feet. The fronds are bi-tripinnate, but the pinnæ and pinnules are extremely variable upon different plants, both in length and breadth. They are thin in texture and bright green in colour. This species is extremely rare in cultivation. Native of Nepaul, Sylhet, Java, Ceylon, Penang, &c.

A. ARMATA.—A slender-stemmed species of great beauty, and, also, of great rarity. It produces tripinnate fronds, which vary from 3 to 6 or 8 feet in length, are light green in colour, coriaceous in texture, and sparingly clothed on the under-side with fulvous spreading hairs. The stipes are profusely armed with short, stout, light-coloured spines, whilst the crown of the plant, and the stipes as well, are clothed with large white and fulvous-coloured chaffy scales. Native of Jamaica, and various parts of South America.

A. PROCERA.—I have never seen large stems of this species, but, nevertheless, it is very handsome, even in a young state. The stipes appear to be sparingly furnished with short spines; the fronds are bipinnate, the pinnules being broad and scarcely pinnatifid, and very rich green in colour; the crown and base of the stipes are clothed with brown chaffy scales. I have found this species, which is a native of various parts of Brazil, far more common in German gardens than in this country.

A. RADENS.—A fine species, but little known in cultivation. Its fronds are some 6 or 8 feet in length, and bipinnate; pinnæ from 12 to 18 inches in length; pinnules, pinnatifid; segments, oblong, obtuse, and bright green; stipes and main rachis, aculeate, and very pale. Native of Brazil.

A. INFESTA.—This is a widely-distributed Fern, and, like all plants circumstanced in that way, it varies considerably in appearance in different localities; all forms of it, however, are extremely beautiful. The fronds are bipinnate; pinnules, pinnatifid, broad, and membranaceous in texture, and deep green in colour; the crown of the plant is clothed with chaffy scales, whilst the base of the stipes is armed with some sharp spines. It seems to be common in various provinces of South Brazil, Peru, British Guiana, and some of the West Indian Islands, but I have never seen it recorded from Mexico.

A. ASPERA.—This magnificent species has an extremely slender stem, which, nevertheless, attains the height of some 20 feet, or even more. It bears a magnificent crown of broad bipinnate coriaceous fronds, the pinnæ of which frequently measure from 20 to 30 inches in length, and are rich deep green in colour; the base of the stipes is armed with short stout spines, whilst the main and partial rachis are clothed

with long rough hairs. It is common in several of the West Indian Islands.

A. BEYRICHIANA.—This species I have seen thrive well in a conservatory during the summer months, but it is not wise to risk it in such a position during winter. Its stem is slender, and it bears a fine crown of long arching fronds; the crown of the plant and base of the stipes are clothed with long brown or cinnamon-coloured chaffy scales, the latter being also armed with spines; the fronds are ample, bipinnate, dark green on the upper side, but paler beneath. It is frequently placed amongst the *Cyatheas*, but I have never been able to discover any involucre, the presence of which only would entitle it to a place in that genus. Native of Brazil.

A. PALEOLATA.—Of this species I am only acquainted with young plants, but these bid fair to produce grand specimens. In general appearance, it would seem to approach *A. ferox*, but this latter plant would seem to be involved in some mystery, judging from the different forms which I have seen bearing that name. The fronds of *A. paleolata* are bipinnate, clothed on both sides with downy hairs, more dense beneath than above. The stipes are aculeate, and the rachis somewhat hispid; pinnæ serrate, and deep green. It is a Brazilian plant, somewhat scarce in English gardens.

A. SURINAMENSIS.—This species has only come under my notice in a young state, or, perhaps, it would be better to say that the stems of such plants as I have seen of it were young, and I have not seen them imported in a large state. The stem is slender, and bears a beautiful crown of fronds, which are bipinnate, with the pinnules pinnatifid, and deep green. The crown of the plant is furnished with large brown chaffy scales; the stipes are aculeate, whilst the costæ and main rachis are slightly pubescent below. Native of Guiana and Martinique.

A. VILLOSA.—This is an extremely rare and beautiful species, with the size of the full-grown stem of which I am unacquainted. The stipes are unarmed; fronds tripinnate, the pinnæ having a peculiar habit of pointing forward instead of spreading horizontally; they are dark green on the upper side and smooth, but below they are clothed with dull-coloured woolly hairs. Owing to its beauty and distinctiveness, this species should receive more extended cultivation than it has hitherto been accorded. It is a native of Brazil, Caraccas, and elsewhere.

A. FEROX.—The stem of this is slender, and, being clothed with the somewhat persistent bases of the aculeate stipes, it presents a formidable appearance. The fronds are broad and ample, bipinnate, the segments being finely and elegantly divided, which gives it a beautiful feathery appearance; they are dull deep green above, and slightly paler below, where they are furnished with a few bullate scales. It is a very handsome Brazilian Tree-Fern, and one which deserves a place in every stove Fernery. With the above enumeration, I shall leave this genus for the present, not because of paucity of material, but because several have recently come to us with new names, the value of which I am anxious to prove.

Lophosoria.

L. PRUNIATA.—There would seem, according to the majority of authors, to be no reasons for separating this plant from the genus *Alsophila*; nevertheless, I cannot help entirely concurring with Mr. J. Smith, when he says, "Setting aside the arborescent character of the stem, this genus is more naturally related to the *Desmopodium* section of *Phegopteris* than to *Alsophila*." This, however, in a cultural point of view, will not affect us. It has an erect stout stem, like an *Alsophila* or *Cibotium*, with the fructification of a *Polypodium*. The largest stems which have come under my notice were between 3 and 4 feet in height, the crown and base of the stipes being densely clothed with tawny hairs; the fronds are from 3 to 5 feet long, three times divided; the pinnules deeply toothed at the edges, deep bright green on the upper side, but silvery-white beneath. It is a truly beautiful stove species, deserving the attention of all lovers of Ferns. It is a native of various parts of South America and elsewhere.

Trichopteris.

T. EXCELSA.—With some, this plant is retained in the genus *Alsophila*; but, to me, it seems to have so many points of distinction, that I must, perforce, adopt the system of those

who separate it from that genus. It is a beautiful plant, rising upon a rather slender stem, the base of the stipes and crown of the plant being enveloped with large dark reddish-brown chaffy scales. As a point of distinction, I may here observe that the stipes are articulated with the axis, and the pinnules are articulated with the rachis. It is important not to neglect to water this species, for its pinnæ never recover from drought, like those which are sessile, but fall out at the joint, and leave only bare sticks in place of beautiful foliage. The fronds are bipinnate; from 3 to 6 feet in length; pinnules lanceolate, entire, and about 2 inches long; they are coriaceous in texture, smooth, and dark shining green on the upper side, slightly paler below, where the peculiar bearded sori form a continuous line midway between the costæ and margin. This rare and handsome species requires stove temperature. It may, perhaps, be better known to some of our readers by the name of *Alsophila Tænitis*. Native of various parts of Brazil. G.

Epiphyllums as Basket Plants.—These are excellent plants either for large or small baskets. When large wire baskets are employed these plants may, if grafted near the base of the stock, be planted between the meshes of the wire, where they grow and bloom freely, and, even when out of flower, the shoots are always fresh and green. They may, likewise, be planted and tastefully intermixed with other flowering plants in such baskets, and, in this way, owing to their pendent habit, greatly relieve any prevailing stiffness. Chatsworth conservatory is famous for its suspending baskets furnished with *Epiphyllums*, and with which their whole surface and base are decorated, and when, as at Chatsworth, they have the advantage of a little artificial heat, they bloom from the end of October till after Christmas. At Dalhousie, I observed, the other day, an ingenious method of exhibiting these plants to advantage. Mr. Dickson, the gardener there, having some nice plants with well furnished drooping heads, grafted from 8 to 12 inches high, and growing in 48-sized pots, wished to use them as basket plants in the conservatory. As he had no baskets, however, he tied some Moss neatly around the pots, so as to entirely hide them, and, with some wire, suspended them as required. The effect is excellent, and, as the plants were grown in a cool greenhouse, they did not begin flowering till Christmas, and even now (February 13) they are as thickly laden with beautiful fresh blossoms as one might expect them to be in December.—W. F.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Pitcher Plants (*Sarracenia flava*).—Those who have seen the fine specimens of this very curious plant at our great shows, may be interested to learn that in North Carolina and Virginia, it sometimes grows in immense quantities in the wet ditches on each side of the railway track.—R.

Odontoglossum Pescatorei.—A small plant of this beautiful Orchid has just flowered at Drumlanrig, bearing fifty-five flowers on a spike, and, in addition to this, it bore a smaller spike from the apex at the pseudo-bulb. This plant was grown in a four-inch pot, and is a grand illustration of the profuse-flowering character of this fine winter-blooming *Odontoglossum*, one of the best we have in cultivation.—B. W. F.

Tuberose.—When is the time to buy and plant Tuberose; and do they require much heat?—G. [Obtain good strong bulbs now, and plant them in light sandy soil. A warm greenhouse or Vinery suits them as regards temperature. They grow freely in Southern Europe and America planted out in warm moist soils. Much of your success depends on the bulbs you purchase being sound and thoroughly well ripened.—Ed.]

Bouvardia Culture.—Are Bouvardias grown in cool-houses or hothouses?—G. [Bouvardias are generally grown in slightly heated pits or frames, the lights being removed during the summer months, except in dull wet weather. In some warm soils and sheltered situations they will succeed planted out-of-doors like bedding-plants. They like a light sandy compost, one-third of which should be well-rotted manure. During winter they should have a temperature of 55°.—Ed.]

Mulching Pots and Tubs with Sphagnum.—In the Royal Botanic Gardens, Edinburgh, Mr. McNab mulches the soil in the large tubs and pots containing Palms, Ferns, and other plants, with common Sphagnum, and he considers this to be of material benefit to the plants, especially in the case of such as are newly-potted. The mulching prevents hasty evaporation in bright sunny weather, and thus saves a great deal of watering; it also assists in maintaining the soil in such a condition as to enable water to readily percolate equably throughout the whole mass. The stems of delicate or newly-shifted Tree-Ferns, too, are likewise wrapped in Sphagnum in order to encourage fresh roots.—W.

Rope-refuse for Mulching and Hot-beds.—This material, usually called "pob" may be obtained in large quantities from rope manufactories. In the Lawson Nurseries it is used for hot-beds. After being soaked with water, fermentation soon commences, and, when once warm, it retains its heat for at least twelve months. Owing to its chaffy character, it could not, of itself, be built into a hot-bed above ground, but in pits, and indoors it forms a good substitute for tan and becomes a valuable fertiliser when soaked with liquid-manure, or mixed with dung, and, in this respect, it is more useful than tan, which in any form but that of ashes, is valueless as manure. "Pob" is also used as a mulching for plants both in and out-of-doors, and for this purpose, it is quite as valuable as Cocoa-nut fibre.—F.

THE DATE PALM IN EGYPT.

(PHŒNIX DACTYLIFERA.)

AMONG the numerous kinds of Palms to be found in tropical and semi-tropical countries, the Date Palm is one of the most useful to the swarthy Arabs of Northern Africa and to the bronzed children of Southern Europe. To the inhabitants of the Arabian and African deserts it is second only to bread. Although the Date Palm is found in cultivation more or less from Southern Europe to Hong Kong, probably in no country is it to be met with in greater abundance than in Egypt, a country from which hundreds of tons of Dates are annually exported in a dry and pressed state. There are two varieties of the Date Palm in Egypt, one having a large brownish-red fruit, and the other a golden-yellow one. The former is chiefly used when fresh gathered, and that variety is not so much in cultivation as the yellow kind. In travelling in Egypt, when the tops of the Date Palm come into view it is always the signal that a village or town is at hand. In the neighbourhood of Alexandria, there are some splendid groves of the Date Palm, which also surround every town and village in the Nile Delta, where it is extensively cultivated. The district of Fiumee, which is about 100 miles above Cairo, is, however, most celebrated for its Dates, and likewise for its Grapes. It is watered by an immense canal cut from the Nile, and known by the name of "Bahr el Yussef" (Joseph's River), which has been the means of bringing into cultivation a large and fertile district which otherwise would have been a desert.

The Date Palms of Egypt are very sturdy in their growth, rarely rising higher than from 40 to 50 feet. One solitary Palm, however, growing near the Pacha's palace at Abdeen, in Cairo, measures about 80 feet in height, and has a thin and graceful stem; this has probably arisen from its growing in a shaded court, but as seen from the front entrance of the palace it has a most picturesque appearance, backed up, as its feathery foliage is, by the minarets and towers of the neighbouring mosques. Every wealthy Arab has a garden adjoining his residence, containing Roses and Myrtles, Date Palms, Figs, Vines, Peaches, Apricots, Plums, and Pomegranates, all mingled together in a kind of wild disorder. Such is the bountiful nature of the soil and climate of Egypt that, if irrigation is only attended to, crops of every kind are produced in quantities that would astonish English cultivators. The Arab loves his garden, and it is only in it that he and his family throw off that stiff dignity for which they are so celebrated—roaming about in careless freedom, and sitting on mats under the trees eating whatever fruit may please their fancy.

The Date Palm is a great source of revenue to the Egyptian Government, each individual tree being heavily taxed. Like the Cocoa Nut Palm, every portion of it is applied to some useful purpose. When the lower fronds ripen and become useless to the tree, they are cut off, converted into bedsteads or couches for the poorer classes, or are made into baskets and bird-cages; and the net-like fibre that occurs at the base of the fronds, termed by the Arabs "lif," is made into coarse rope cables for the Nile boats. The usual mode of propagating the Date Palm is by means of suckers severed from the foot of the older trees. In forming plantations, it is necessary to plant a certain number of male plants, other-

wise the fruit-bearing Palm would be sterile; one male for every ten female trees is generally found to be sufficient. In cases in which the male plants have died, it is not unusual to cut male flower-spathes, and to tie them to the fruit-bearing trees, fertilisation being simply left to the action of the winds. Few sights are more pleasing than a Date Palm grove while in flower—i.e., when the bursting spathes display the half-green and golden colouring of the inflorescence. One Date Palm often produces a bushel of Dates.

PETER WALLACE.

A POISONED LAND.

WARRINGTON is a busy centre surrounded by a belt of spoiled or partially wasted land. One cannot leave the town without having to go through one of these scathed and blighted districts that fill one with melancholy. There is the river, once a source of fertility and beauty, some hundred years ago abounding with salmon, and even twenty years ago furnishing a constant supply of some kinds of delicate fish, but now a great disgusting ditch. The river is innocent and pure compared with Sankey Brook, and the Sankey Canal, whose fetor

poisons for some half-mile on either side, and whose poison has turned that once smiling valley, through which they flow, into a dismal swamp. It is questionable whether there be a tiny water-course, within miles of the town, that is not polluted and spoiled; ceasing to be the source of beauty, fertility, and health that nature intended, and becoming instead a loathsome eyesore. Then, how miserable it is to see healthy vegetation disappearing all around. The fine trees in Arpley Meadows, that delighted every lover of the beautiful, are one by one dying, and, if still surviving in a few instances, they only look unspeakably wretched. If, in this melancholy zone around us, fruit trees anywhere are left, they are become fruitless and useless, wrecks of what they were a few years ago. The very hedgerows look wasted and melancholy beyond description, the ghosts of their former selves. And no wonder vegetation cannot endure the injurious influences that are poured into the air around us, for, if anyone has been unfortunate enough to have to cross the trail of one of the worst of the destroyers, especially at night, his smarting eyes and burning throat testify to something very deadly, being sent abroad and sometimes the evil thing is much more potent even than this.

Such is the picture drawn by the *Warrington Guardian* of the country around. Now, it would be great folly and injustice to cast the blame of all we decry on this or that offender, or plume ourselves that we had nothing to do with it. Every man who burns a fire, unless he also consumes his smoke, contributes in a degree, though, perhaps an infinitesimally small one, to the ruin and desolation we are deploring. But we mainly owe this terrible state of things to the manufactures that have enriched us. And is this necessary? Is the destructive and deforming influence inseparable from our manufacturing processes? Science on all hands declares that these hurtful results are not only needless and wasteful. Science declares that the man who poisons the fields and the trees with his smoke, in just the same proportion wastes his own fuel; that the man who sends acids up his chimney to fall in a scorching blight on every living thing around, also at the same time wastes chemical products it would pay him far better to condense and utilise.

A PEASANT at Lauzerte (Tarn-et-Garonne) is said to have recently discovered a Grey Truffle, as large as a Pumpkin. The weight of this treasure was not, however, proportioned to its size, for deep in its fragrant recesses was found the ancestral home of a family of field-mice.

The Date Palm.

GARDEN DESTROYERS.

THE WOODLOUSE.

(ONISCUS ASELLUS.)

THE little creature figured in the accompanying cut (known in many districts by the name of "Slater," probably from being found in numbers under slates and in similar localities) is not an insect. It looks like one, but it crosses the border and belongs to the class of Crustaceans, of which lobsters and crabs are the most honoured members. Its proper function is that of a scavenger, but, as the human scavenger sometimes exceeds his duty in sweeping up things which are not yet past use or which may be of value, so the Oniscus does not content itself with feeding on the detritus and decaying vegetable matters, which it is its proper business to consume, but, when it finds its way into a hothouse, takes a fancy to costly living plants, more especially Orchids, and occasionally does them a good deal of harm. In the open border they also attack herbaceous plants. It is no uncommon thing to see some of these which spread themselves over the ground, and so furnish a fine shelter to insects, grow sickly and, on examination, it will then be found that there is a crowd of young Onisci beneath, which have been eating the collar or neck of the plant just above the ground until they have nearly entirely removed the outer ring, and so destroyed the plant. When they get into an Orchid-house it is difficult to dislodge them, for they establish themselves among, and make galleries through, the Sphagnum in the baskets, or where the Orchids are growing. The gardener may be surprised at seeing his plants bitten and fading. He may turn over every bit of slate, tile, broken pot, wood, bark, or anything else that might serve as a hiding-place, and see nothing—and unless he watch during the night, and catch the culprits at work (for they are nocturnal animals)—never find out that it is these Onisci that have done the mischief, and that their hiding place is about the plant itself. There are several species—some grey, others nearly black, all paler beneath. Their life is longer than that of most insects, as they live, and seem to increase in size, for several years. They have the faculty of rolling themselves up like a Pea, in the same manner as the hedgehog, whence their French name "cloporte," as we should say "one who closes the port or door." No wholesale mode of destroying them is known. They must be cut off in detail, and the same sort of contrivances which are had recourse to to entrap earwigs and surface larvæ must be used against them. Scooped out Potatoes placed like little domes, up into which they can creep, and little heaps of decaying plants, turfs, &c., may be left, and the under-side examined every morning, and by degrees, with care and attention, they may be thus thinned out until the garden is freed from them.

A. M.

THE RED-BELTED CLEARWING.

(SESIA MYOPAEFORMIS.)

THE caterpillars of the Sesiæ, the most interesting family amongst British moths, are viewed, perhaps, with greater satisfaction by the entomologist than by the gardener; but, being, with one or two exceptions, far from numerous in their occurrence, they seldom do any very material injury to the gardener, whilst their occasional discovery gives to the naturalist very considerable satisfaction. Many also confine themselves to forest trees, only feeding in the Oak (*Quercus robur*), Elm (*Ulmus campestris*), and one species has been known to do much damage amongst the Osiers (*Salix viminalis*). Perhaps the commonest and most mischievous in the gardens is the Currant Clearwing (*Sesia tipuliformis*), which eats away into the stems of Currant trees, causing them to die off when attacked. The Sesiæ may be said, with truth, to be the most beautiful of the moths, their wings being of such a transparent appearance and such a delicate gauzy texture, their bodies of such frail construction and their movements so capricious and lively, dancing, as they do, in the air in the broad daylight, and exhibiting their graceful evolutions in the brightest sunshine. The caterpillars cannot be said to have quite such a charming appearance, those which are known being for the most part dirty white and maggot-like.

The Red-belted Clearwing (*Sesia myopaeformis*), of which I am now treating, is of a dirty white or yellowish colour, with a few light hairs, and four black spots arranged in a square on each segment; the second, third, and fourth segments are darker than the remainder of the body; the head is brown, with a brown plate behind it, and the hind part of the thirteenth segment is brown also. The moth appears on the wing during the summer months, and has rather the appearance of a bee, a fly, or a gnat, than of a moth; so much so, that anyone unacquainted with its characteristics would be much surprised to find that it belonged to the latter sub-order of insects, the clear wasp-like wings being so totally different from those soft mealy-looking ones which most people expect to see in a moth; the body is black, with a red ring round it, from which it takes its name. The caterpillar feeds on the solid wood of Pear and Apple trees, sometimes a great number being found in close proximity, and has been observed principally in the southern parts of England; the specimen before me was sent from Sheerness.

OWEN WILSON.

BLACKBIRDS.

My thanks are due to your correspondents for their advice, and the means they recommend for ridding my garden of these pests. "J. T.'s" advice to hang up a hat would, I fear, prove of no use here, the blackbirds being far too bold and knowing to be scared by that means. Like him I am also robbed of my Peas to a great extent by the titmouse, but I do not find its depredations extend to other vegetables or fruit. Three years ago I tried "J. L. H. S.'s" plan of having hawks in my garden. They were kestrels, and greedily devoured any small dead birds thrown to them, but were quite useless for driving away the live ones, their wings being necessarily clipped. I have also tried, and with some success, the following plan to protect my Strawberries:—Parallel with a border in which they grow I strained a long wire to two posts, one at each end of the bed, driven into the gravel walk; upon this wire was a running ring and a short string and collar, to which a cat was attached; he could thus walk the length of the wire, and though he spent much time asleep in a box provided as a refuge from rain, his presence certainly kept the birds away from the Strawberries. Of course this plan could only be adopted on an open walk, and not among bushes. Mr. Tillery's baited rat-traps I shall certainly try if I can discover his particular kind, with which I am unacquainted. "R.'s" quotation from Mr. Tennyson is very pretty, still I do not agree with him that the blackbird is a glorious singer. He is as inferior in note to the thrush as he exceeds him in numbers and mischief, and I only regret the Laureat's poem was not addressed to the latter bird instead of to the most voracious, and, as far as my experience goes, the worst of the many pests of the garden.

BAD SHOT.

The Water Rat (*Arvicola amphibius*) in Gardens.—One day in August last I noticed a large heap of freshly turned-up earth among growing Potatoes in our garden, and thinking a mole to be the cause, a trap was procured, and next morning the culprit was secured. At the first glance I took it to be a common brown rat, but looking at it more closely found it was a water rat or vole and the man from whom the trap was procured declared that these aquatics burrow quite as much as the mole itself. This I do not dispute, seeing the effect of its industry around, but what I consider very strange, is the fact of this lover of water being located in a walled-in garden at a great distance from its more congenial haunts. In Letter 28 of White's "Selborne," a somewhat similar instance is related, the rev. gentleman being apparently as much puzzled as myself to account for such a deviation from regular habits. In that case, the animal was turned up by the plough in a chalky field at a distance from water, and was snugly ensconced in an "hibernaculum," well provisioned with Potatoes.—*Science Gossip*.

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

Pitcher Plants and Ants.—The pitchers of these plants entrap ants and drown them in the liquid. The large pitchers on Mr. Baines's well-grown plants contain myriads of dead ants. The fringe of down-pointing spines round the lid prevents their escape.—R.

Mealy Bug and the Chelsea Blight Composition.—The mealy bug having attacked our Vines, when they were at rest, after being pruned, and without being scraped, they were well dressed with the "Chelsea Blight Composition," care being taken that it did not touch the eyes, and also that it was well rubbed in all crevices. It was used pure as it came in the bottle. This was done three years ago and we have not seen a bug since. The Vines were not harmed in any way from the dressing.—JOHN TAYLOR.

THE KITCHEN GARDEN.

CAULIFLOWERS.

ACCORDING to nurserymen's catalogues, there are a great many kinds of Cauliflower, all of which are highly eulogised; nevertheless, old and tried kinds should not be discarded. Indeed, the Walcheren is, perhaps, the best of all for general purposes, and some even confine their supply throughout the season to the produce of this one kind. Of late years, however, Veitch's new Solid Late is a true solid white-curded sort, and a valuable and good improvement on the Walcheren for a late supply. The Early Cauliflower, or Early London White, as it is sometimes called, is another good sort, and the one generally used for the earliest spring crop. Large Asiatic is a stronger-growing variety of the Early London, producing a fine large, compact curd, and, if sown at the same time as the Early London, it will form a fine succession to it. Snow's Winter White is an excellent kind, and pretty hardy. In the market-gardens round London this is the kind used for affording a supply from the latter end of October till January. Severe frost, however, will prove detrimental to it as well as to other kinds; but, as a rule, it is the hardiest and most suitable for late work, and its quality is first-rate. With these four sorts, rightly treated, no garden should be without a good supply of Cauliflowers from April to Christmas.

Sowing and Transplanting.

Some sow the winter crop, to be protected under hand-lights and in frames, broadcast, in 4 feet beds, about the 20th or 25th of August in the south of England, and in the northern districts from the 1st to the 12th, according to the inclemency, or otherwise, of the locality; if a cold one, sow early, but if a warm one, sow late. Sowing in the open ground is generally preferred, and the 25th of August is the best time, as a rule, for warm parts of England, and the 12th for Scotland. The soil for the seed-beds should be a good friable well-worked loam, which, if manured for the previous crop, should not be again manured for the seedling Cauliflowers. In case of failure, a few seeds may be sown a week afterwards. As soon as the plants have fairly come up, thin them out to 3 inches apart, and with a short-handled 2-inch hoe loosen the surface soil; this will promote a nice stocky habit in the plants. As soon as there is any likelihood of severe weather, a cold frame should be prepared for them, and a layer of sweet, open, and well-pulverised soil should be placed therein, about 8 or 10 inches from the sashes. Into this the plants should be transplanted, 6 inches apart if space can be spared; if not, at the very least, they should be 4 inches apart each way. For a few days after being transferred to their new quarters, the sashes should be kept on, and a little shading placed over them. This, however, should be discontinued as soon as possible; and the plants, as soon as they take to the soil, should be well exposed, the sashes being entirely removed from off them throughout the day, and also at night, unless the weather is very frosty or unsettled. It is sometimes necessary to cover the sashes over with litter, in order to exclude hard frosts; this covering should be removed every morning, and the sashes tilted up a little. Mildew frequently finds its way amongst the plants, but it may easily be extirpated by scattering dry wood-ashes amongst them occasionally. I have found that they winter best in frames, if the surface of the soil therein is covered over with a thin coating of finely-sifted old lime-rubbish. In February, the plants should be transplanted to the open ground, by lifting them carefully with a good ball, and placing them out in clumps of three (C^o), 9 inches from plant to plant, and 2 feet clump from clump, under a hand-light, in a well-manured, deeply-worked, thoroughly-drained, and not too stiff soil. These clumps should be in rows about 4 feet apart, so as to have plenty of room to cover the lights with litter at night and in cold weather. In order to have Cauliflowers in April, it is necessary to place a good layer of litter around the base of the hand-lights, so as to keep the soil moderately warm, and to exclude the cold and piercing winds of early spring. Air is freely admitted by moving the upper half of these portable protections. In the evenings of February and the earlier parts of March, the litter should also be shaken over the whole,

and removed in the morning. The plants will soon become rather tall for their quarters; then a brick can be placed below each of the four corners of the hand-lights, and a little earth drawn around, which, along with the litter, will make the base air-proof. Occasional applications of manure-water in the latter end of March and in April will greatly improve their condition.

Under Hand-lights and Matted Hoops.

Another way of wintering Cauliflowers, is to sow at the time previously recommended, but, instead of pricking off into frames, the young plants are placed, at once, under hand-lights. In this instance, nine, instead of three, are left, and as they become too close, some are lifted and planted out under other lights, until only three or four remain under each cover. Planted thus, they require much the same care as the others, a constant watch, and protection with litter, and a little manure-water in spring, being necessary. In some places they are, also, planted out from the seed-bed in the end of October to other beds, keeping the plants 4 inches apart each way. In these beds they are protected in winter by means of mats supported by hoops, and, in very severe weather, some litter is also shaken over the mats. This is an unwise practice, however, for, should the weather be severe for any considerable length of time, they must be kept dark, consequently they become weak and spindly, and are apt to suffer in a proportionate degree.

Sowing in Frames and Potting.

Where time and convenience can be commanded, the following is a certain method by which success may be attained:—viz., sow the seed in a frame in October, the frame being very gently heated by means of half-decayed leaves and decomposed frame linings mixed together and formed into a basis, 18 or 20 inches deep, for the frame. As soon as the plants come up and have attained a little strength, they should be thinned out and either transplanted into another similarly-prepared frame, 4 inches by 6 inches apart, or potted singly. In potting, use 3-inch pots and good loamy soil and sand; plunge the pots near the glass in frames, until severe frosty weather has arrived, when they could be taken and placed near the glass in Vineries or Peach-houses at rest, but from which frost is excluded, or they may be left in the frames and protected with litter. In the latter end of January shift them into larger pots, using a richer compost than before, and by the end of February, or 1st of March they will be fine plants for planting out in threes under hand-lights, or to shift into larger pots to be placed in late Vineries or Peach-houses, or under any old spare lights in turfpits. I have found the Seakale pots—as soon as out of use—turned upside down, and filled with good rich soil, famous for getting in the first early Cauliflowers under shelter.

Wintering on Warm Borders.

Cauliflowers are not quite so tender as is sometimes thought, and good produce may be had by wintering the plants out-of-doors. This is by no means confined to the southern and warmer districts of England and Ireland, but is successfully practised in Scotland. For this purpose, sow at the usual time, and prepare a S.E., S., or S.W. wall border, say about 2 feet wide from the base of the wall. Into this, prick off the plants about 4 inches apart each way in October, and allow them to remain there till February or March. If they are well sheltered, they do not require any care or protection, further than to keep them clear of the tree-leaves that will naturally collect amongst them, which, if allowed to remain, will bleach and weaken them—but, if convenient, a few sprigs of Broom or Spruce stuck in front of them will be of material benefit to them. In spring, they may be planted out like those already referred to, but for planting out in rich sheltered borders, and unprotected, they are much more suitable than any of those more carefully wintered. The practicability of this method may be understood from the fact that it is almost the only one practised along the coast of the Moray Firth and for four miles inward.

Distance apart, and Intermediate Crops.

When there is room, Cauliflowers reared under hand-lights should have at least 3 feet clump from clump, and 4 feet row from row. The lines planted out without the assistance of

bell-glasses or hand-lights, and from which the second crop is obtained, should be 3 feet apart, and 2 feet plant from plant. Some may think such a large space extravagant, but it is not so. In the case of the first, the room is required in winter and in February for conveniently attending to the protecting material, and on the 1st of March two lines of Lettuces can be planted along the central space, and a plant or two between each clump. These Lettuces will be fit for use before the Cauliflowers are, and so can be removed, thus allowing the Cauliflowers greater room for perfecting themselves. A pinch of Cauliflower seed should be sown every fortnight from the 1st of January until the first week in July, for planting out in succession throughout the summer, on the dampest coldest aspects, between the rows of late high-growing Peas, that is, planted in lines 10 or 12 feet apart, purposely to afford partial shade for summer Cauliflowers, or a few rows of Turnips, or for Celery to succeed summer Spinach, all of which are fond of such a position during the hot summer months. The Cauliflowers sown in June and July, and planted out in succession as fast as the plants are large enough, afford a good autumn and winter supply. I always took care to have a large portion coming in on borders in the months of November and December, in order to pull up just as they were beginning to form their flower-heads, and hung them up with their leaves and roots entire in bunches, each containing from four to six heads, to the rafters and beams of thatched sheds, and this I have found an invaluable practice for affording a good supply up to March. Those sown on gentle heat close to the glass in the middle of October, and pricked off, as fast as they could be handled, into small pots, and plunged immediately close to the glass, either in frames or pits, and shifted on as they grew, some into Seakale pots, or large flower-pots as before advised, will produce fine flower-heads about the end of March. Others planted out under hand-glasses in February, in good rich soil, with slight protection when the weather requires it, and an occasional supply of tepid manure-water, will produce fine flower-heads in April. Thus we may never be a month without this useful vegetable. Cauliflowers sown in August and September should be sown in an exposed situation, on poor, but well pulverized, soil, and when fit, they should be pricked into the same sort of soil, and, the same should be attended to as regards pricking them into frames, or they are too apt to get too large and soft, and, when subject to winter checks, they will start prematurely, and prove useless when planted out.

JAMES BARNES.

Duration of the Germinating Power of Seeds.—A correspondent of the *Revue Horticole*, in sending the following notes to that journal, states that they were communicated to him by a friend who had ample opportunities for making trustworthy observations on the subject. The figures indicate the number of years in each case, in which the seeds may be depended upon as preserving their vitality or power of growth; although, in most cases, they must not be considered a minimum of limitation. They represent the periods of time after which the various seeds mentioned have been found perfectly good, and may be of some use as a guide to those who are uncertain whether to throw away or sow old packets of seeds:—Seed of Artichoke (Globe) lasts good for 5 years; Asparagus, 4; Basella, 3; Basil, 6; Beans (garden), 6; Beans (French), 2 to 3; Beet, 5; Burnet, 2; Cabbage, 5; Cardoon, 7; Carrot, 4; Cauliflower, 5; Celery, 7; Chervil, 2; Chicory, 8; Corn-Salad, 4; Cress (garden), 5; Cress (Water), 4; Cucumber, 5; Dandelion, 1; Egg-plant, 7; Endive, 8; Fennel, 6; Gourds, 5; Leeks, 2; Lettuce, 5; Maize, 2; Melon, 5; Mustard, 5; Nasturtium, 5; Onions, 2 to 3; Onions (Welsh), 2; Orache, 1; Parsnip, 1; Parsley, 3; Peas, 4 to 5; Pepper (long), 4; Potatoes, 3; Purslane, 8; Radish, 5; Rampion, 5; Rhubarb, 3; Salsify, 2; Savory, 3; Scorzonera, 2; Sorrel, 2; Spinach, 5; Spinach (New Zealand), 5; Strawberry, 8; Thyme, 2 to 3; Tomato, 5; and Turnip, 5.

Peas and Lettuces.—Would you kindly inform me what kind of Pea the London growers use for their best, or early, general crop; also, what White Cos Lettuce they grow?—A SMALL GROWER. [The London market-gardeners grow two sorts of Cos Lettuces, the Green Paris Cos, and the London White Cos, the latter being a select variety of the White Paris Cos. Both kinds are used for a first crop, but after May, the London White Cos is depended on solely till winter sets in. Market-gardeners always save their own seeds, and if one of them is short of seed of any particular variety, he gets it from his neighbours. As to Peas, Mr. Myatt, of Deptford, grows Beck's Little Gem for his first crop, sown in lines 2 ft. apart, and Alpha for his second, in lines 2½ ft. apart. To neither sort does he apply any stakes; of the two, he considers the latter the best.—ED.]

THE ARBORETUM.

THE WEEPING OAK AT KING'S ACRE.

MR. CRANSTON'S nurseries at King's Acre, famous throughout the land for their large stock of superbly-grown Roses, contain also many objects of much interest to lovers of trees and plants. Among the trees, perhaps, the most striking is a fine specimen of the Weeping Oak—that is to say, of the weeping form of the common Oak. Being much struck by the appearance of the tree, when at Hereford last summer, Mr. Cranston had a photograph taken of it at our request, and from this the accompanying illustration has been engraved. It will be seen that it is a noble tree of its kind, and that its branches are gracefully pendulous. It was planted by the present Mr. Cranston's grandfather, when the nursery was established, in the year 1785. It was grafted about 3 feet from the ground, and, though scarcely perceptible in our illustration, there is a slight increase in the size of the trunk, at the point of union between the graft and the stock. It bears quantities of Acorns every year, but none of the seedlings raised from them has shown the least disposition to droop. The height of the tree in question is 64 feet, and the distance between the ground and the lowest branches is 18 feet. The girth of the trunk, at 4 feet from the ground, is 8 feet, and the width through the branches 58 feet. We may add that the aspect of this tree reminded us of that of some of the Oaks of the plains and foothills of California, belonging to species not yet to be seen in our grounds. These trees, like Mr. Cranston's Oak, show no sign of the pendulous tendency at the top, but weep, in a very picturesque manner, from the outer parts of the lower branchlets. This peculiarity of form among our weeping trees is a precious one, inasmuch as the contrast between the rigid upper portion of the tree and the pendulous outer and lower parts forms a very striking and attractive feature, quite distinct from the aspects usually presented by any other kind of weeping trees.

W. R.

ARBORICULTURAL NOTES FROM PERTH.

By JAMES M'NAB.

THE nursery grounds of Messrs. Dickson & Turnbull, at Perth, have long been well known to cultivators. They were established in the year 1766, and from them have emanated many new and useful plants. Amongst flowering plants may be mentioned the first set of double Scotch Roses, which were so much in fashion about forty years ago, but which are now, I regret to find, scarcely ever asked for. The original stools of these Roses still exist, and are capable of producing many thousand plants again should they ever be required. These Roses were admirably adapted for the climate of Scotland, and if they were again taken in hand by our southern friends, and received a little of the attention paid to other garden varieties by hybridisation, a new breed might be procured suitable for this country. The original superb scarlet-flowering Thorn was likewise raised in this nursery. This establishment was also the seed-bed of the first Swedish Turnips ever sent to Britain, seeds of which were sent by Linnæus to this firm about the year 1772, and now this hardy vegetable is spread over all the temperate quarters of the globe. Mr. Robert Brown, one of the early partners of the firm (formerly Dickson & Brown), was the first discoverer in Scotland of *Menziesia cærulea*, specimens of which still exist in this establishment, being sub-divisions of the original plants found by Mr. Brown on the Sow of Athole, in Perthshire. For many years the bog, or dwarf American plants, indeed, all kinds requiring peat soil, have been cultivated in this establishment with success, and few nurseries in the kingdom contain a greater variety of these interesting plants. The various species of *Ammyrsine*, *Andromeda*, *Azalea*, *Bryanthus*, *Cassiope*, *Fothergilla*, *Gaultheria*, *Ledum*, *Daboecia*, *Menziesia*, *Rhodora*, *Vaccinium*; also hardy Heaths and dwarf *Rhododendrons*, with numerous others, are cultivated here to an extent which is not often seen. These choice plants have not been receiving of late years that attention from cultivators which they did in former times; nevertheless, none are more attractive than

THE WEEPING OAK IN THE KING'S ACRE NURSERIES, HEREFORD.

they are for rock-garden or for ornamental-clump cultivation, few even surpassing them for general interest.

Conifers.

The Perth Nurseries have long been noted for their extensive collection of Coniferous plants. They contain no fewer than 300 species and varieties of all the leading sorts. The variegated forms now constitute one of the chief features of this establishment, and, during the winter months, give an effect to Coniferous collections such as they would not otherwise possess. The variety among variegated Yews is of itself remarkable, to say nothing of the gold and silver colouring of some of the species of the genera *Cupressus*, *Biota*, *Chamaecyparis*, *Juniperus*, *Retinospora*, *Sciadopitys*, *Thuja*, and *Wellingtonia*. Here, also, is a large collection of *Podocarpus Koraiana* or *japonica*, all stem-pruned, which makes them assume the character of gigantic Irish Yews. By the pruning treatment, this *Podocarpus* forms an admirable plant, hardy, and well worthy of being cultivated in ornamental grounds. One of the great advantages belonging to the Perth Nursery is its collection of specimen Conifers, the different kinds of which, being arranged side by side, afford great assistance to purchasers, who can see at a glance matured specimens from which to select what they require. The ornamental forest-tree department is also well represented, no fewer than 470 species and varieties being cultivated in stock. The varieties of Ash, Beech, Birch, Elm, Hornbeam, Plane, Lime, Maple, Oak, Poplar, Walnut, and Chestnut are now very numerous; the Oaks, both evergreen and deciduous, particularly so. No fewer than sixty-six species and varieties of this genus alone are under cultivation. Of late years the rage for Coniferæ has rather had a tendency to retard the planting of what are commonly called evergreen and deciduous hard-wood forest trees, but I trust the time is not far distant when a return to these well-known hardy and majestic forest ornaments must again take place. With a few exceptions, including the well-known species of *Abies*, *Cedrus*, *Picea*, and *Pinus*, most of the recently-introduced Coniferæ are very well up to a certain size, but when they become of tree growth, unless in partially sheltered situations and particular soils, they are often disfigured by wind and snow. Besides, after many years' trial how few of the new Conifers do we find assuming a proper tree growth, so as to take the place of, or even cope with, the old kinds now existing, and thoroughly free from the attacks of insects-pests, which, in one shape or another, have proved very detrimental to many Coniferous trees throughout the country. The spread of these, I fear, will rather increase than diminish—depending on the mildness or severity of the winter months. Many of the Conifers are mere shrubs, and, as such, they are beautiful, and for this quality they should be more widely cultivated; but a general feeling seems to prevail amongst their admirers that they must become forest trees, and for this end they are extensively planted. Perhaps the most attractive of the recently-introduced Conifers, and one which may in time be likely to assume a proper tree growth, is the *Cedrus atlantica*, or African Cedar. It is a kind which I strongly recommend to be grown as ancestral trees. For avenue purposes, no evergreen tree of recent introduction, as far as has yet been tested, seems better adapted to the climate of Scotland, provided that it is carefully attended to during its early growth by stem pruning, so as to secure straight stems and proper leaders, I have never seen it injured by judicious and timely pruning. The *Taxodium sempervirens* is another Conifer of comparatively recent introduction, and one which may be planted for avenue purposes in many sheltered situations in Scotland, but, like the African Cedar, must be early stem-pruned and branch-pointed. It, however, is, perhaps, better adapted for the climate of England, where it grows well, but is frequently unshapely, from the want of pruning. The Douglas Fir, in some districts of the country, is beginning to prove itself a useful tree, but whether these trees were produced by cuttings from original specimens, or raised from imported seed, remains to be proved. The first trees raised from British-ripened seed have certainly not turned out in every quarter as was expected. The *Picea Nordmanniana* may, in time, afford useful timber, but, like other trees I have mentioned, it must be prepared for this end at an early stage of its growth. As generally seen in nursery establish-

ments, the spread of its branches is often considerably more than the height, and, when they once get into this condition, it is difficult to get them out of it, without a very free use of the knife, which, at an advanced state of their growth, may do more harm than good. With early branch-pointing or pruning, the *Picea Nordmanniana* suffers no injury, and starts admirably into a tree habit after the operation. I am also much impressed by the Lawson Cypress—*Cupressus Lawsoniana*. Judging from the time it has been in the country, and its appearance in certain soils and situations, I feel satisfied that it is a Conifer likely, some day or other, to become a useful timber tree, but not if left in a bush form, as it is generally seen in cultivation. If stem-pruned at an early stage of its growth, it takes on an upright habit; on this account many trees may be grown on a limited space. In its natural condition it attains to the height of 100 feet, and the timber is said to be good. An upright form of this Cypress, and one which originated in the Perth nursery, is likely to become a useful tree if planted in suitable soil. It has naturally only one stem, instead of ten or twenty, which is not unusual in the ordinary unpruned bush-formed specimens. The Lawson Cypress is, without exception, one of the hardiest of the recently-introduced Conifers, and will succeed in any soil or situation. It stands the smoke, and is, therefore, well adapted for town gardens. It can be increased to any extent by cuttings or seeds, of which many are now produced in Britain. When propagated by cuttings, a portion of the bare cutting stalk should be kept above the surface of the soil, which enables them to take on an upright habit immediately after being rooted. I also find that the *Wellingtonia*, in very exposed places, when early stem-pruned, say at three or four years old, assumes a compact tree form, stands the wind well, and is less liable to have dead or brown points than those specimens which have been planted in sheltered situations without any pruning whatever.

Ornamental Deciduous Trees.

Although I have a strong feeling for growing Coniferæ, it is doubtful if there are many of the recently-introduced species that will ever take the place of the ornamental evergreen and deciduous forest trees which are frequently to be seen throughout the country, and which, I regret to say, are not increasing to the extent they are justly entitled to, standing, as they do, all weathers, wind and snow, and remaining as monuments to their planters. Many of these old ornamental hard-wood trees are of great interest, and I confess that I have infinitely more pleasure in looking at them, than on any Coniferous tree in this country, excepting, however, the Scotch and Silver Fir; also, the majestic Cedars of Lebanon, as seen in many English parks. In the Perth nurseries, two well-balanced specimens of the Lucombe Oak exist, one 8 feet in circumference, and the other 8 feet 9 inches, and averaging about 70 feet in height. A large purple Beech is also a noble specimen; it stands about 60 feet high, with a stem 10 feet in circumference. A large Tulip-tree, in a neighbouring garden, is 8 feet 6 inches in circumference. Surely such specimens as these, which stand every blast with impunity, ought to be planted in preference to many of the Coniferous trees. They become stately with age, and we know that they will make trees, and ultimately prove an ornament to the landscape, and a credit to their planters; while, with many of the Coniferæ, we are planting only in hopes that they may, perhaps, succeed. After all that has been done for the Coniferæ, we find that it is only in some exceptional places that they can ever assume their true tree character, and these exceptional places cannot be got on every property. Spots for deciduous trees are everywhere to be met with, and I should like to see them again taking the place which they held before the great Coniferæ fever set in about twenty-five or thirty years ago. The finest specimen of a Coniferous tree, in the Perth Nurseries, is the *Abies Douglasii*, which was planted on the 28th of June, 1838. The circumference of the stem is now 6 feet; spread of branches, 36 feet; and the height about 65 feet. It is certainly a beautiful tree, but I have great doubts if it will go on improving for many years longer, and, even if it does, it never will have the appearance, nor yet the duration of the noble Lucombe Oaks, just alluded to. It is absolutely neces-

sary that all fine or exceptional trees should be attended to, by having fresh soil occasionally laid on the surface of the ground over their roots. The ground under such trees is often hard, by being much trodden on by visitors. The two Lucombe Oaks, at Perth, are apparently of the same age, and were probably planted at the same time, and by the same hands. One specimen is 9 inches more in circumference than the other, and the difference is evidently owing to the harder nature of the surface ground round the smaller tree. The surface-dressing of the ground over the roots of exceptional trees is a most important subject, and one which ought to be more generally attended to all over the country than it now is. Weeping and pyramidal ornamental forest trees are also extensively cultivated here. Nearly all the genera furnish us with weeping or pendent varieties, as well as variegated forms. Variegated varieties ought to be more grown than they now are, for they are equally hardy with the typical sorts; and the landscape effect produced by these varieties against the green sorts is, as yet, comparatively little known and practised.

Tree Knowledge, especially as to Soils, wanted.

One of the great drawbacks to the more general planting of ornamental hard-wood forest trees rests very much with the nurserymen themselves. In very few firms, with the exception of the ordinary or old-established ones, which are generally very well managed, are collections of both new and old sorts carried out with the same spirit as they were in the days of Loudon. It requires nurserymen to be thoroughly read up in the subject of new and rare trees, and their nature, as regards soil and climate, to induce gentlemen to invest in them. There are many landed proprietors throughout the country anxious to take an interest in the preservation of arboricultural subjects, apart from Coniferæ, but, unless assisted by the practical and sound advice of nurserymen, they feel unwilling to enter into them to any extent. About half a century ago, such arboricultural knowledge, with reference to deciduous trees, was much more diffused over the country than it now is. Good practical instruction on all the new and rare Coniferæ, and ornamental flowering trees, is everywhere to be found, but sound advice on deciduous forest trees is a rarer article now than in the olden times. Hamburgh used to be the great school for all the new arboricultural products, and now such establishments are freely scattered over the continent of Europe. Although large establishments exist in Britain for ornamental forest trees, they lack the zeal of some of our continental neighbours. There are large tracts of country in Great Britain yet to be planted, and, by a little effort on the part of nurserymen, many gentlemen might be induced to invest largely in certain kinds, instead of taking one or two on trial, which may get injured by accident, and are then set down as unworthy of cultivation. In some districts of Scotland, certain species of forest trees succeed well, which in others (having soil and situation apparently similar) are comparatively scarce, such as the Cedar of Lebanon, Silver Fir, Norway Maple, Plane-tree, Walnuts, Chestnuts, &c. On some estates Chestnut-trees are seen of giant form, and of centuries standing, while on others they are unworthy of observation; whether from soil or climate, or both, requires to be proved. Soil and situation have much to do in the planting and grouping of many of our rare trees, and this information can only be obtained from nurserymen who have paid strict attention to such matters, and even with them it is sometimes impossible to get a judicious off-hand answer as to what ought to be planted, even when furnished with information as to exposure, elevation, and the general nature of the soil. A conference amongst nurserymen, from various parts of the country, would be of great service in communicating such information, each possessing, in some parts of his nursery, soils suitable for certain species of trees, but often quite different from each other. Such a conference would have a tendency to bring about a more widely-spread cultivation of many species of forest trees, different from those now under general culture. It is well known that certain kinds will not succeed on all soils and situations; many species, therefore, may be set down as unworthy of cultivation. By some it may be said that the *Picea cephalonica* and *P. Pinsapo*, are not worth growing; in many places they are not, but, if

planted in a limestone district, they become highly ornamental trees. The same remark holds good with the *Abies Menziesii*, *A. Albertiana*, and *A. excelsa*, when grown in any soil, save that naturally of a peaty description. The effect of soils on the growth of certain trees, shrubs, and plants, is of more importance than we are generally aware of. What is in the soil in the neighbourhood of Aberdeen which causes the fruit of the Strawberry to be carried with safety to the Glasgow markets, while that grown nearer the city is often destroyed in the course of transit? It is not from any nicety in packing, but from some quality which the fruit itself must derive from the soil, and we find this to be the case, also, with many trees. In certain soils the timber of one species of forest tree is found to be more durable than in others. These are points which a conference of nurserymen and foresters can alone bring out. Much has been done for the analysis of soils for agricultural purposes, but its full influence has not been brought to bear on all horticultural products, and much is still wanted in the science of arboriculture. It is well-known that certain plants, in a state of nature, are only found in peat soils, more or less mixed with sand, and any attempt to cultivate them in other mixtures fails; leaf-mould and sand does, however, suit some of the peat plants. Who would ever think of planting Cape Heaths or *Epacris* in leaf-mould, or manured loam, although other species of plants thrive freely in such mixtures? This fact, alone, shows that there is something in the composition of certain soils only suitable for the roots of a certain class of plants. In most nursery establishments, it is the common practice to have a piece of ground made up entirely with peat earth, to accommodate a large section of plants which naturally grow in such soils, and these are procured from all the temperate quarters of the globe. Many of the so-called American, or peat plants, are frequently planted in other soils and mixtures. If they do live, they rarely ever assume the vigorous form and colour of those grown in the natural peat, or in sandy loam, mixed with one-half its bulk of peat. If lime happens to be accidentally put into the soil where *Rhododendrons* or other plants are placed, they are certain to sicken and die. It is, perhaps, not generally known, although several amateur cultivators have experienced it to their cost, that, when laying in a stock of peat turf, they not unfrequently mix with it some fresh lime, in order to decompose it more rapidly, and render it fit for immediate use, as is occasionally done for the surface-dressing of land. When peat is so mixed up, and placed into beds for *Rhododendrons*, *Azaleas*, *Kalmias*, *Heaths*, &c., the plants are certain to become yellow, and ultimately die out. This fact shows that certain forms of vegetation will not succeed in soils where others freely thrive, because composed of certain ingredients unsuited for their constitution. It is remarkable, however, that there is no class of plants, whether evergreen or deciduous trees and shrubs, Alpine or herbaceous plants, epiphytal or terrestrial, from all climates, and procured from all soils, that refuse to grow in earth having a certain proportion of peat in its composition. An occasional visit to country nurseries is often conducive of much good. I first visited the Perth establishment nearly forty years ago, and I still find that, at the present day, it maintains its pre-eminence as a nursery. It was here that I first interested myself in the dwarf American plants, and I am glad to find that it still maintains its superiority in that special department.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Cotoneaster thymifolia as a Standard.—This, though a creeping rock-shrub, makes a good standard. In the Lawson Nurseries I observed, the other day, several nice examples in this way grafted from 3 to 6 feet high on *C. affinis*, which makes a suitable stock, either for this or for other kinds of *Cotoneaster*.—W. F.

Trees for Lawns.—The following is a select list of twelve small hardy trees for lawns of limited extent, by G. Ellwanger, of the celebrated Mount Hope Nurseries, Rochester, U.S.A.:—Imperial cut-leaved Alder, cut-leaved Beech, large double-flowering Cherry, Californian Buckeye, white-leaved Linden, *Magnolia Soulangiana*, Wier's cut-leaved Maple, Oak-leaved Mountain Ash, Paul's Double Scarlet Thorn, *Virgilia lutea*, cut-leaved Birch, and Kilmarnock Willow.

Chimonanthus fragrans.—This useful wall shrub is now flowering freely in many gardens around London. Its blossoms are not showy, but they emit a delicious fragrance like that of Cloves. The plant itself is deciduous and blooms before the foliage appears. It may interest some to know that there are at least two forms of it, one bearing flowers nearly twice the size of the other. This is known as *C. fragrans grandiflorus*, and will be found much handsomer than the common form, and equally odorous.—B.

THE GARDEN IN THE HOUSE.

PRINTING FERN-FRONDS.

I HAVE read with very great interest the directions on Fern-leaf printing, as given at page 124, and, as the process which I have practised with good results is somewhat similar, perhaps a few remarks may not be out of place. The materials I use are—A grainer's comb, a common tooth-brush, a cake of lamp-black, an old plate to mix it on, and a few sheets of blotting-paper. Almost any kind of card-board answers admirably to begin to print on, and it may be cut into any shape the operator thinks proper, and can then be made into very pretty work-baskets, &c., edged with blue, green, or pink ribbon, according to taste, these being most useful for small presents, for Christmas-trees, and bazaars. All leaves or fronds for printing should be carefully pressed between blotting-paper, or, what will answer equally as well, in an old book. The fronds about to be printed should be carefully and neatly pinned to the card-board, as has been recommended. Having your lamp-black or ink already mixed, dip your tooth-brush into the ink, holding the comb in the left hand, then draw your brush over your comb till shaded according to taste. The brush should be shaken almost dry before using, for the smaller the spots the more delicate the tints which will be obtained. When the prints become dry, replace the Ferns between blotting-paper till required again. After being used a few times, they become brittle, and are then of little use for printing purposes. By following these directions, with a little practice, it is almost impossible to fail. Varieties of the following make beautiful prints:—*Adiantum*, *Asplenium*, *Athyrium*, *Davallia*, *Lastrea*, *Lomaria*, *Polypodium*, *Polystichum*, and many others. I send you a specimen done by the above process to show you of what this system of Fern-printing is capable.

THOS. BEAUCHAMP.

[The specimen sent was a beautiful portrait of *Adiantum formosum*, and other foliage in pure white on a delicately-tinted ground.—ED.]

The Creeping Myrtle (*Myrsiphyllum asparagoides*).—Mr. J. Vick, than whom there is no better authority, gives the following directions for the household culture of this plant, now so much used in floral decorations, for twining in the hair, and for trimming party dresses:—"With a little care it can be grown successfully as a house plant. The seeds should be sown in a box or in pots in the house, and should be kept moist till the young plants appear. The seed being rather slow to germinate, you must not think it bad if it does not make its appearance in two weeks. The young plants should be potted off into 3-inch pots as soon as they are 3 or 4 inches high. Once a year the bulbs should be allowed to dry off and rest. They will start into growth again in about six weeks. The plant does not require the full sun, but will grow well in a partially-shaded situation. It can be trained on a small thread across the window or around pictures. It is a climber, and will attach itself to a string in just about the right condition to use for wreaths, &c., or, when required for lighter work, the branches which become entangled can be separated." This plant, perhaps the most universally employed of all by the American florists, and generally most tastefully used, seems to make slow progress with us. It is of easy culture in the greenhouse.—DELTA.

Griselinia macrophylla as a Window Plant.—This is an evergreen shrub, of only moderate growth, and one which has thick, bright green, succulent-like leaves, wherein consists its chief beauty. It is partial to a good loamy soil and some decayed manure, but almost any good soil will suit it, and it has no objection to peat or leaf-soil. It requires no special care nor more warmth than that afforded by a dwelling-house window, and, if hardily nursed, will bear a slight frost with impunity. It is one of the best window plants that can be grown. In a cottage near Glasgow, the other day, I saw two plants of it in a 6-in. pot; the owner had obtained them three years ago, and, since he first possessed them, he has not re-potted or top-dressed them, but has kept them within a window in a room where gas is nightly burned. During the summer time he occasionally places them out of doors to get the rain or a "wash," as he terms it, and sometimes he lays them on their sides and pours water over them through a watering-pot rose, an operation which answers as well as syringing. He waters them when they are dry, giving more in late spring and summer than he does in winter. They are not very subject to the attacks of insects, damp, or any diseases, and dust can easily be sponged off their leaves. These plants, although well attended to, have been grown under circumstances by no means favourable for the past three years, yet they retain their leaves and colour well, and are bright and cheerful in appearance.—F.

THE FRUIT GARDEN.

CORDON PEAR WALL AT HOLME LACY.

WHEN at Holme Lacy last summer, we were pleasantly surprised to see a wall covered with Pear-trees, trained as single cordons, and in the finest bearing condition. We learnt from Sir H. Scudamore Stanhope that he had taken some interest in their mode of culture some years ago in France, and made several experiments, this plantation of winter Pears being one of them. He has kindly furnished us with the photograph from which our sketch was engraved, and the following account of the trees:—

"Allow me to furnish you with an illustration of my Cordon Pear wall, one-half of which, planted in December, 1861, bore fruit in 1864; another half, planted in March, 1865, bore fruit in 1868. From the time these trees began fruit-bearing up to the present date, they have been, and are now, perfectly healthy, and have yielded large crops every year, with the exception of two or three trees, perhaps, which may miss bearing each year; as to the superiority of the fruit, in size, appearance, and flavour, over fruit grown in my garden on pyramids and espaliers, there can be no question. In hot summers it was found necessary to mulch, and even to water them, owing to the Quince stock, on which all are grafted, having more fibres and rooting nearer the surface than the Pear stock. They are trained on a south wall, which, however, is somewhat shaded by large Oaks, and, although this circumstance renders the wall unfavourable for Peaches, I do not consider it has been against these Quince-grafted Pears, as, but for the shade, they would probably have suffered more in hot summers than they have done. I do not, therefore, think a south wall, by any means, a necessity, for the successful culture of cordon Pears in the south and west of England. As to the pruning, my late gardener writes as follows:—"My experience in pinching has never been what I was led to expect; never, but in one solitary instance, have I found the fruit-bud to be the result of that practice, and even that one being so far from home, so to speak, would have to be cut off in order to keep the spur short. But that was not all, for I have found that what was once a decided fruit-bud would lengthen and grow into wood before the growing season closed." I myself certainly think that the pinching cannot be carried out in our climate to the same extent as in France. The result with us was to produce too many wood-shoots. Whether this is the result of a richer soil and a moister climate or not, I cannot say. The merit of the successful results of the cordon-wall is due to my late gardener, Mr. Wells, now at Osborne Park Nurseries, Potter's Bar. The following are the weights of some of the cordon-grown Pears, produced by trees which have always been allowed to bear freely, viz.:—*Glou Morceau*, 13½ oz.; *Beurré Bosc*, 12½ oz.; *Beurré Superfin*, 14 oz.; *Van Mons*, 15 oz.; *Easter Beurré*, 16 oz.; *Beurré Diel*, 15 oz.; *Zéphirin Grégoire*, 11½ oz.; *Triomphe de Jodoigne*, 14 oz.; *Joséphine de Malines*, 11 oz.; *Doyenné d'Alençon*, 13¾ oz.; *Duchesse d'Hiver*, 18½ oz.; *Bergamotte d'Esperen*, 11½ oz.; *Conseiller de la Cour*, 14 oz.; and fruit from *Doyenné Boussoch*, *Beurré Hardy*, *Madame Millet*, *Williams's Bon Chrétien*, *Figue d'Alençon*, and *Beurré Sterckmans* have weighed equal to these, as have also *Duchesse d'Angoulême*, and many others."

Among the many interesting features of Holme Lacy, there is none more worthy of being seen by gardeners and fruit-growers than this wall of Pear trees, of the beauty of which our engraving gives but a very imperfect notion.

RASPBERRY CULTURE.

I DO not agree with Mr. Hobday when he says (see p. 149) that Raspberries are at their best in the third year of their growth. They may certainly produce good fruit then, but, nevertheless, it does not follow that they will not produce a much heavier crop when they are three or four times as large. The second year, if one good cane has been planted, we may expect from two to three canes, but oftener two than three. These will bear a good crop, but not equal to that obtainable from three to four canes in the third year, or from six good canes in the fifth year. To allow all the young canes to remain the first two or three years tends to induce premature exhaus-

tion. What does it matter how many years the plants have been in the same position if we get sound well-ripened canes that produce fruit as good as that from plants of three or four years' standing? Raspberries cannot be compared, as regards treatment, with many other fruit trees, because they produce young wood every year; without it they will bear no fruit, and, as long as we can get it good, it is all we desire. I have in my eye a plantation of Raspberries, of from twenty to thirty years' standing, that cannot be easily beaten now. I thoroughly appreciate rotation, but for its sake, alone, I would not destroy a good standing crop. Late Raspberries are at times, in dry autumns, highly appreciated, and are very useful; but servants, as well as employers, look more to an early crop than a late one. I have sent late Raspberries to table often, and have well nigh as often found them, some days afterwards, thrown away in a mouldy state. Have late Raspberries by all means; but do not encourage the plants that bear the principal crop to produce them. Mr. Hobday must have a good climate not to have seen Rasp-

A CURIOUS FACT IN POT-VINE CULTURE.

WE have a Vinery here 60 feet by 13 feet, lean-to, with a partition in the middle for growing pot-Vines, and it may be thought strange that we force both ends at the same time, but the reason is that Grapes in May are in such demand with us that one house cannot supply us with them. The varieties chiefly consist of Black Hamburgs and Sweetwater, with a few other sorts for trial. The Vines stand in two rows, plunged in leaves in a bed in the middle of the house, and I am happy to say are looking well. But here comes the singular part of the matter. In consequence of the fire being at one end, of course that compartment is always from $2\frac{1}{2}$ to 3 degrees higher in temperature than the other, and, strange as it may appear, the Grapes in the coldest end are ready for the scissors while those in the hottest end are barely in flower. Both myself and my foreman stand and look at each other in reference to the matter in amazement, but can form no idea as to the cause of such an anomaly. Moreover, we grow French Beans along the front, and with the same results, those in the cold end beating the

Cordon Fruit-wall at Holme Lacy, Herefordshire.

berries killed by frost. I had a row of a new sort killed two years ago, and I have seen whole quarters destroyed in different places. I will give Mr. Hobday a nut to crack. Some years ago, when under a good practical gardener, we planted some four or five rows of Raspberries, I think 6 feet by 3 feet. They grew immensely for the first two or three years, producing canes like Bamboos, with an eye in a foot, little wood being in the canes, but plenty of pith. They were not killed whilst I was there; but, if a hard winter had occurred, there would have been no hope for them. Strange to say, these canes bore but little fruit; the gardener came to the conclusion that another row planted between them would have the desired effect, and, sure enough, as soon as they got established, the others began to bear prodigiously. That was in the fourth or fifth year after being planted. The gardener good-naturedly told me that fruitfulness in this case was brought about by the planting the other rows between them. Though young, my ideas were different; and, after exchanging opinions, he confessed that I had the better of him. What was the reason?

J. TAYLOR.

others by fully a week. This leads me to say a few words on bottom-heat for pot-Vines. Many fancy that bottom-heat makes them break with more regularity than they otherwise would do, and also sooner than those to which it has not been given. Never was a greater mistake, as the following fact will show. We grow a dozen Vines for the table; these were placed on the curbstone in the house just adverted to, and they broke equally strong and early as those subjected to bottom-heat, while in former years they swelled off their fruit equally well.

"Say, why is this, and wherefore, and what shall we do?"—Hamlet.
Burghley, Stamford.

R. GILBERT.

Peaches Shedding their Buds.—What is the cause of buds falling off Peach trees in the Peach-house?—G. [Drought at the root, and irregular temperature often cause Peach trees to shed their flower-buds.—Ed.]

Shading Vineries.—Do you advise shading the glass in Vineries where sunshine is very powerful? They are glazed with 21 oz. glass.—G. [No; that is if provision has been made, which, in all such cases, there should be, for ample ventilation.—Ed.]

THE DAISY, ITS HISTORY, POETRY, AND BOTANY.*

By the Rev. H. N. ELLACOMBE.

I do not apologise for the lowness and humbleness of my subject, but, with "no delay of preface" (Milton), I take you at once to it. In speaking of the Daisy, I mean to confine myself to the Daisy, commonly so called, merely reminding you that there are also the Great or Ox-eye, or Moon Daisy (*Chrysanthemum leucanthemum*), the Michaelmas Daisy (Aster), and the Blue Daisy of the South of Europe (*Globularia*). The name has been also given to a few other plants, but none of them are true Daisies. I begin with its name. Of this there can be little doubt; it is the "Day's-eye," the bright little eye that only opens by day, and goes to sleep at night. This, whether the true derivation or not, is no modern fancy. It is, at least, as old as Chaucer, and probably much older. Here are Chaucer's well-known words—

Well, by reason, men it call may,
The Daisie, or else the Eye of the Day,
The Empresse, and floure of floures all.

There is, however, another derivation. Dr. Prior says "Skinner derives it from daïs or canopy, and Gavin Douglas seems to have understood it in the sense of a small canopy in the line—

The Daisie did unbraid her crounall small.

"Had we not the A. S. dæges-æye, we could hardly refuse to admit that this last is a far more obvious and probable explanation of the word than the pretty poetical thought conveyed in Day's-eye." This was Dr. Prior's opinion in his first edition of his valuable "Popular names of British Plants," but it is withdrawn in his second edition, and he now is content with the Day's-eye derivation. Dr. Prior has kindly informed me that he rejected it because he can find no old authority for Skinner's derivation, and because it is doubtful whether the Daisy in Gavin Douglas's line does not mean a Marigold, and not what we call a Daisy. The other derivation, however, seemed worth a passing notice. Its other English names are Dog-daisy, to distinguish it from the large Ox-eyed Daisy, Banwort, "because it helpeth bones to knyt agayne" (Turner); Bruisewort, for the same reason; herb Margaret from its French name; and in the north Bairnwort, from its associations with childhood. As to its other names, the plant seems to have been unknown to the Greeks, and has no Greek name, but is fortunate in having as pretty a name in Latin as it has in English. Its modern botanical name is *Bellis*, and it has had the name from the time of Pliny. *Bellis* must certainly come from *bellus* (pretty), and so it is at once stamped as the pretty one even by botanists—though another derivation has been given to the name, of which I will speak soon. The French call it *Marguerite*, no doubt for its pearly look, or *Pasquerette*, to mark it as the spring flower. As Pliny is the first that mentions the plant, his account is worth quoting. "As touching a Daisy," he says (I quote from Holland's translation, 1601), "A yellow cup it bath also, and the same is crowned, as it were, with a garland, consisting of five and fifty little leaves, set round about it in manner of fine pales. These be flowers of the medow, and most of such are of no use at all, no marvile, therefore, if they be namelesse; howbeit, some give them one tearme and some another."—Book xxi., cap. 8. And, again, "There is a hearbe growing commonly in medows, called the Daisie, with a white floure, and partly inclining to red, which, if it is joined with Mugwort in an ointment, is thought to make the medicine farre more effectual for the King's evil."—Book xxvi., cap. 5.

We have no less than three legends of the origin of the flower. In one legend, not older, I believe, than the fourteenth century (the legend is given at full length by Chaucer in his "Legende of Goode Women"), Alceste was turned into a Daisy. Another legend records that "this plant is called *Bellis*, because it owes its origin to Belides, a grand-daughter to Danaus, and one of the nymphs called Dryads, that presided over the meadows and pastures in ancient times. Belides is said to have encouraged the suit of Ephigeus, but whilst dancing on the Grass with this rural deity she attracted the admiration of Vertumnus, who, just as he was about to seize her in his embrace, saw her transformed into the humble plant that now bears her name." This legend I have only seen in Phillips's "Flora Historica." I need scarcely tell you that neither Belides or Ephigeus are classical names—they are mediæval inventions. The next legend is a Celtic one; I find it recorded both by Lady Wilkinson and Mrs. Lankester. I should like to know its origin, but with that grand contempt for giving authorities which lady-authors too often show, neither of these ladies tells us whence she got the legend. The legend tells that "the virgins of Morven, to soothe grief of Malvina, who had lost her infant son, sang to her, 'We have seen, O! Malvina, we have seen the infant you regret, reclining on a light mist; it approached us, and shed on our fields a harvest of new flowers. Look, O! Malvina.' Among these flowers we distinguish one with a

golden disk surrounded by silver leaves; a sweet tinge of crimson adorns its delicate rays; waved by a gentle wind, we might call it a little infant playing in a green meadow; and the flower of thy bosom has given a new flower to the hills of Cromla." Since that day the daughters of Morven have consecrated the Daisy to infancy. "It is," said they, "the flower of innocence, the flower of the newborn." Besides these legends, the Daisy is also connected with the legendary history of S. Margaret. The legend is given by Chaucer, but I will tell it to you in the words of a more modern poet:—

There is a double flouret, white and rede,
That our lasses call Herb Margaret
In honour of Cortona's penitent;
Whose contrite soul with red remorse was rent,
While on her penitence kind Heaven did throwe
The white of puritie surpassing snowe;
So white and rede in this fair floure entwine,
Which maids are wont to scatter on her shrine.
("Catholic Florist," Feb. 22, S. Margaret's Day.)

Yet, in spite of the general association of Daisies with S. Margaret, Mrs. Jameson says that she has seen one, and only one, picture of S. Margaret with Daisies.

The poetry or poetical history of the Daisy is very curious. It begins with Chaucer, whose love of the flower might almost be called an idolatry. But, as it begins with Chaucer, so it almost ends with him. Spenser, Shakespeare, and Milton scarcely mention it. It holds almost no place in the poetry of the seventeenth and eighteenth centuries; but, at last in the nineteenth century, it has the good luck to be uprooted by Burns's plough, and he at once sings its dirge and its beanties; and then the flower at once becomes a celebrity. Wordsworth sings of it in many a beautiful verse; and I think it is scarcely too much to say that since his time not an English poet has failed to pay his homage to the humble beauty of the Daisy. I do not purpose to take you through all these poets—time and knowledge would fail me to introduce you to them all. I shall but select some of those which I consider best worth selection. I begin, of course, with Chaucer, and even with him I must content myself with a selection:—

Of all the floures in the mede,
Then love I most those floures white and redde;
Such that men callen Daisies in our town.
To them I have so great affection,
As I said erst when comen is the Maye,
That in my bedde there dawneth me no daie,
That I n'am up and walking in the mede
To see this floure against the sunne sprede.
When it upriseth early by the morrow,
That blessed sight softeneth all my sorrow.
So glad am I, when that I have presence
Of it, to done it all reverence—
As she that is of all floures the floure,
Fulfilled of all virtue and honoure;
And ever ylike fair and fresh of hue,
And ever I love it, and ever ylike new,
And ever shall, till that mine heart die,
All swear I not, of this I will not lye.
There loved no wight hotter in his life,
And when that it is eve, I run blithe,
As soon as ever the sun gaineth west,
To see this floure, how it will go to rest.
For fear of night, so hateth she darkness,
Her cheer is plainly spread in the brightness
Of the sunne, for there it will uncloze;
Alas, that I ne had English rhyme or prose
Suffisaunt this floure to praise aright.

I could give you several other quotations from Chaucer, but I will content myself with this, for I think unbounded admiration of a flower can scarcely go further than the lines I have read to you.

Stephen Hawes, who lived in the time of Henry VII., wrote a poem called the "Temple of glass." In that temple he tells us—

I saw depycted upon a wall,
From est to west, fol many a fayre image
Of sturdy lovers.

And among these lovers

And Alder next was the freshe quene,
I mean Alceste, the noble true wife,
And for Admete howe she lost her life,
And for her trouthe, if I shall not lye,
How she was turned into a Daysye.

We next come to Spencer. In the "Muiopotmos," he gives a list of flowers that the butterfly frequents, with most descriptive epithets to each flower most happily chosen. Among the flowers are

The Roses raining in the pride of May,
Sharp Isole good for greene woundes' remedies,
Faire Marigolds, and bees-alluring Thyme,
Sweet Marjoram, and Daisies decking prime.

* Read at a meeting of the Bath Naturalists' Field Club.

By "decking prime" he means they are the ornament of the morning. Again he introduces the Daisy in a stanza of much beauty, that commences the June eclogue of the shepherd's calendar.

Lo! Colin here the place whose pleasant syte
From other shades hath weand my wandering minde.
Tell me, what wants me here to work delyte?
The simple ayre, the gentle warbling winde,
So calm, so cool, as no where else I finde,
The Grassie ground with daintie Daisies dight;
The Bramble bush, where byrdes of every kinde,
To the waters' fall their tunes attemper dight.

From Spencer we come to Shakespeare, and, when we remember the vast acquaintance with flowers of every kind that he shows, and especially when we remember how often he almost seems to go out of his way to tell of the simple wild flowers of England, it is surprising that the Daisy is almost passed over entirely by him. Here are the passages in which he names the flowers. First, in the poem of the "Rape of Lucrece," he has a very pretty picture of Lucrece as she lay asleep—

Without the bed her other faire hand was
On the green coverlet, whose perfect white
Showed like an April Daisy on the Grass.

In "Love's Labour Lost," is the song of Spring, beginning—

When Daisies pied, and Violets blue,
And lady-smocks all silver-white,
And Cuckoo buds of yellow hue
Do paint the meadows with delight.

In "Hamlet," Daisies are twice mentioned in connection with Ophelia in her madness. "There's a Daisy!" she said, as she distributed her flowers; but she made no comment on the Daisy as she did on her other flowers. And, in the description of her death, the queen tells us that—

Fantastick garlands she did make
Of Crow-flowers, Nettles, Daisies, and Long Purples.

And in "Cymbeline" the General Lucius gives directions for the burial of Cloten—

Let us
Find out the prettiest Daisied plot we can,
And make him with our pikes and partisans
A grave.

These are the only four places in which the Daisy is mentioned in Shakespeare's plays, and it is a little startling to find that of these four the first is in a song for very absurd clowns, and the second and third are in the hands of the poor mad princess. I hope that you will not use Shakespeare's authority against me, that to talk of Daisies is fit only for clowns and madmen. I am not so much surprised to find that Milton barely mentions the Daisy. His knowledge of plants was very small compared to Shakespeare's, and seems to have been, for the most part, derived from books. His descriptions of plants all savour more of the study than the open air. I only know of two places in which he mentions the Daisy. In the "l'Allegro" he speaks of "Meadows trim with Daisies pied," and, in another place, he speaks of "Daisies trim." But I am surprised to find the Daisy overlooked by two such poets as Robert Herrick and George Herbert. Herrick sang of flowers most sweetly; few, if any, English poets have sung of them more sweetly, but he has little to say of the Daisy. He has one poem, indeed, addressed specially to a Daisy, but he simply uses the little flower, and not very successfully, as a peg on which to hang the praises of his mistress. He uses it more happily in describing the pleasures of a country life—

Come live with me and thou shalt see
The pleasures I'll prepare for thee,
What sweets the country can afford,
Shall bless thy bed and bless thy board.
Thou shalt eat
The paste of Filberts for thy bread,
With cream of Cowslips buttered;
Thy feasting tables shall be hills,
With Daisies spread and Daffodils.

And again—

Young men and maids meet,
To exercise their dancing feet,
Tripping the comely country round,
With Daffodils and Daisies crowned.

George Herbert had a deep love for flowers, and a still deeper love for finding good Christian lessons in the commonest things about him. He delights in being able to say

Yet can I mark how herbs below
Grow green and gay.

But I believe he never mentions the Daisy. I must not, and I need not, dwell on the other poets of the seventeenth century. In most of them a casual allusion to the Daisy may be found, but little more.

Nor need I dwell at all on the poets of the eighteenth century. In the so-called Augustan age of poetry, the Daisy could not hope to attract any attention. It was the correct thing if they had to speak of the country to speak of the "Daisied" or "Daisy-spangled" meads, but they could not condescend to any nearer approach to the little flower. If they had, they would have found that they had chosen their epithet very badly. I never yet saw a "Daisy-spangled" meadow. The flowers may be there, but the long Grasses effectually hide them. And so I come *per saltum* to the end of the eighteenth century, and at once to Burns, who brought the Daisy into notice. He thus regrets the uprooting of the Daisy by his plough.

Wee, modest, crimson-tippèd flower,
Thou'st met me in an evil hour;
For I must crush amongst the stour
Thy slender stem.
To spare thee now is past my power,
Thou bonny gem.

Cold blew the bitter, biting north,
Upon thy humble birth,
Yet cheerfully thou ventarest forth
Amid the storm,
Scarce reared above the Parent-earth
Thy tender form.

The flaunting flowers our gardens yield
High sheltering woods and walks must shield;
But thou, between the random field
Of clod or stone,
Adorn'st the rugged stubble field,
Unseen, alone.

There, in thy scanty mantle clad,
Thy snowy bosom sunward spread,
Thou lift'st thy unassuming head
In humble guise;
But now the share uptears thy bed,
And low thou lies!

With Burns we may well join Clare, another peasant poet from Northamptonshire, whose poems are not so much known as they deserve to be. His allusions to wild flowers always mark his real observation of them, and his allusions to the Daisy are frequent; thus:—

Smiling on the sunny plain
The lovely Daisies blow,
Unconscious of the careless feet
That lay their beauties low.

Again, alluding to his own obscurity—

Green turf's allowed forgotten heap
Is all that I shall have,
Save that the little Daisies creep
To deck my humble grave.

Again, in his description of evening, he does not omit to notice the closing of the Daisy at sunset—

Now the blue fog creeps along,
And the birds forget their song;
Flowers now sleep within their hoods,
Daisies button into buds.

And so we come to Wordsworth, whose love of the Daisy almost equalled Chaucer's. His allusions and addresses to the Daisy are numerous, but I have only space for a small selection. First, are two stanzas from a long poem specially to the Daisy—

When soothed awhile by milder airs,
Thee Winter in the garland wears,
That thinly shades his few gray hairs,
Spring cannot shun thee.
While summer fields are thine by right,
And autumn, melancholy wight,
Doth in thy crimson head delight
When rains are on thee.

Child of the year that round dost run
Thy course, bold lover of the sun,
And cheerful when thy day's begun
As morning leveret.
Thy long-lost praise thou shalt regain,
Dear shalt thou be to future men,
As in old time, thou not in vain
Art nature's favourite.

The other poem from Wordsworth that I shall read to you is one that has received the highest praise from all readers, and by Ruskin (no mean critic, and certainly not always given to praises) is described as "two delicious stanzas, followed by one of heavenly imagination." The poem is "An Address to the Daisy"—

A nun demure—of holy port;
A sprightly maiden—of love's court,
In thy simplicity the sport
Of all temptations.

A queen in crown of rubies drest,
A starveling in a scanty vest,
Are all, as seems to suit thee best,
Thy appellations.

I see thee glittering from afar,
And then thou art a pretty star,
Not quite so fair as many are
In heaven above thee.
Yet like a star with glittering crest,
Self-poised in air thou seem'st to rest;
Let peace come never to his rest
Who shall reprove thee.

Sweet flower, for by that name at last,
When all my reveries are past,
I call thee, and to that cleave fast.

Sweet silent creature,
That breath'st with me in sun and air;
Do thou, as thou art wont, repair
My heart with gladness, and a share
Of thy meek nature.

With these beautiful lines I might well conclude my notices of the poetical history of the Daisy, but, to bring it down more closely to our own times, I will remind you of a poem by Tennyson, entitled "The Daisy." It is a pleasant description of a southern tour brought to his memory by finding a dried Daisy in a book. He says:—

We took our last adieu,
And up the snowy Splügen drew,
But ere we reached the highest summit,
I plucked a Daisy, I gave it you,
It told of England then to me,
And now it tells of Italy.

Thus I have picked several pretty flowers of poetry for you from the time of Chaucer to our own. I could have made the posy fifty-fold larger, but I could, probably, have found none more beautiful, nor more curious, than these few.

I now come to the botany of the Daisy. The Daisy belongs to the immense family of the Compositæ, a family which contains one-tenth of the flowering plants of the world, and of which nearly 10,000 species are recorded. In England the order is very familiar, as it contains three of our commonest kinds, the Daisy, the Dandelion, and the Groundsel. It may give some idea of the large range of the family when we find that there are some 600 recorded species of the Groundsel alone, of which eleven are in England. I shall not weary you with a strictly scientific description of the Daisy, but I will give you instead Rousseau's well-known description. It is fairly accurate, though not strictly scientific (in Lindley's "Lady's Botany," Vol. I., p. 199). But Rousseau does not mention one point which I wish to describe to you, as I know few points in botany more beautiful than the arrangement by which the flower is fertilised. In the centre of each little flower is the style surrounded closely by the anthers. The end of the style is divided, but, as long as it remains below among the anthers, the two lips are closed. The anthers are covered, more or less, with pollen; the style has its outside surface bristling with stiff hairs. In this condition it would be impossible for the pollen to reach the interior (stigmatic) surfaces of the divided style, but the style rises, and as it rises, it brushes off the pollen from the anthers around it. Its lips are closed till it has risen well above the whole flower, and left the anthers below; then it opens, showing its broad stigmatic surface to receive pollen from other flowers, and distribute the pollen it has brushed off, not to itself (which it could not do), but to other flowers around it. By this provision no flower fertilises itself, and those of you who are acquainted with Darwin's writings will know how necessary this provision is in perpetuating flowers. The Daisy not only produces double flowers, but also the curious proliferous flower called Hen and Chickens, or Chidding Daisies, or Jackanapes on Horseback. These are botanically very interesting flowers, and though I, on another occasion, drew your attention to the peculiarity, I cannot pass it over in a paper specially devoted to the Daisy. The botanical interest is this:—It is a well-known fact in botany, that all the parts of a plant—root, stem, flowers, and their parts; thorns, fruits, and even the seeds, are only different forms of leaves, and are all interchangeable, and the Hen and Chickens Daisy is a good proof of it. Underneath the flower-head of the Daisy is a green cushion, composed of bracts; in the Hen and Chickens Daisy, some of these bracts assume the form of flowers, and are the chickens. If the plant is neglected, or does not like its soil, the chickens again become bracts. The only other point in the botany of the Daisy that occurs to me is its geographical range. The old books are not far wrong when they say "it groweth everywhere." It does not, however, grow in the tropics. In Europe it is everywhere, from Iceland to the extreme south, though not abundant in the south-easterly parts. It is found in North America very sparingly, and not at all in the United States. It is also by no means fastidious in its choice of position—by the river-side, or on

the mountain-top, it seems equally at home, though it somewhat varies according to its situation, but its most chosen habitat seems to be a well-kept lawn. There it luxuriates, and defies the scythe and the mowing machine. It has been asserted that it disappears when the ground is fed by sheep, and again appears when the sheep are removed, but this requires confirmation. Yet it does not lend itself readily to gardening purposes. It is one of those

Flowers worthy of Paradise, which not nice art
In beds and curious knots, but Nature's boon
Pour'd forth profuse on hill and dale, and plain,
Both where the morning sun first warmly smote
The open field, and where the unpierc'd shade
Imbrown'd the noontide bowers.—"Par. Lost," iv., 240.

Under cultivation it becomes capricious; the sorts degenerate and require much care to keep them true. As to its time of flowering, it is commonly considered a spring and summer flower; but I think one of its chief charms is that there is scarcely a day in the whole year in which you might not find a Daisy in flower.

I have now gone through something of the history, poetry, and botany of the Daisy, but there are still some few points which I could not well range under either of these three heads, yet which must not be passed over. In painting, the Daisy was a favourite with the early Italian and Flemish painters, its bright star coming in very effectively in their foregrounds. Some of you will recollect that it is largely used in the foreground of Van Eyck's grand picture of the "Adoration of the Lamb," now at S. Bavon's, in Ghent. In sculpture it was not so much used, its small size making it unfit for that purpose. Yet you will sometimes see it, both in the stone and wood carvings of our old churches. In heraldry it is not unknown. A family named Daisy bear three Daisies on their coat of arms. In an old picture of Chaucer, a Daisy takes the place in the corner usually allotted to the coat of arms in mediæval paintings. It was assumed as an heraldic cognisance by St. Louis of France in honour of his wife Margaret; by the good Margaret of Valois, Queen of Navarre; by Margaret of Anjou, the unfortunate wife of our King Henry VI.; while our Margaret, Countess of Richmond, mother of our Henry VII., and dear to Oxford and Cambridge as the foundress of the Margaret Professorships, and of Christ College in Cambridge, bore three Daisies on a green turf.

In medicine, I am afraid, the Daisy has so lost its virtues that it has no place in the modern pharmacopœia; but in old days it was not so. Gerard says, "the Daisies do mitigate all kinds of paines, especially in the joints, and gout proceeding from a hot or dry humoure, if they be stamped with new butter, unsalted, and applied upon the pained place." Nor was this all. In those days, doctors prescribed according to the so-called "doctrine of signatures," i.e., it was supposed that Nature had shown, by special marks, for what special disease each plant was useful. Thus, a heart-shaped plant was sure to cure heart-disease; a bright-eyed flower was good for the eyes; a foot-shaped flower, or a leaf badly formed, at once proclaimed its fitness for the gout; and so the little low-growing Daisy must have its uses, and here they are. "It is said that the roots thereof being boyled in milk, and given to little puppies, will not suffer them to grow great" (Cole's "Adam in Eden"). It is said that "for pleasant dreams Dazy roots should be put under the pillow."

On the English language, the Daisy has had little influence, though some have derived "lackadaisy" and "lackadaisical" from the Daisy, but there is, certainly, no connection between the words. Daisy, however, was (and, perhaps, still is) a provincial adjective in the eastern counties. A writer in *Notes and Queries* (2nd Series, ix. 261) says that:—Samuel Parkis, in a letter to George Chalmers, dated Feb. 16, 1799, notices the following provincialisms: "Daisy: remarkable, extraordinary excellent, as 'She's a Daisy lass to work,' i.e., 'She is a good working girl.' 'I'm a Daisy body for pudding,' i.e., 'I eat a great deal of pudding.'"

And I must not leave the Daisy without noticing one special charm, that it is peculiarly the flower of childhood. The Daisy is one of the few flowers of which the child may pick any quantity without fear of scolding from the surliest gardener. It is to the child the herald of spring, when it can set its little foot on six at once, and it readily lends itself to the delightful manufacture of Daisy chains.

In the spring and play-time of the year,
The little ones, a sportive team,
Gather king-cups in the yellow mead,
And prank their hair with Daisies.—*Cowper*.

It is then the special flower of childhood, but we cannot entirely give it up to our children. And I have tried to show you that the humble Daisy has been the delight of many noble minds, and may be a fit subject of study even for those children of a larger growth who form the Bath Field Club.

THE SELF-SOWN OAK WOODS OF SUSSEX.*

By R. W. CLUTTON.

In this paper I propose to inquire into the following matters connected with the growth and management of self-sown Oak woods. Oak will grow in almost any description of clay, from the poorest and stiffest to a good deep loam. As the Oak, in its earliest stages of growth, has a long tap-root, a deep soil, free to a certain depth from rock, is necessary to its rapid development. Oak will grow with considerable luxuriance in a gravelly soil, but, on arriving at a size fit to be called timber, it becomes what is termed shaky, and it will be found on felling to be little more than a bundle of laths, utterly unsuitable for the uses to which Oak timber is generally put.

The Position of Oak Woods as Affecting their Growth.

There is no tree grown in England more sensitive of exposure to wind than the Oak, and the best and fastest growing woods are those in sheltered positions, well inland. There is a tract of country in the south-east of Sussex, lying between Battle and Hailsham, the soil of which is well adapted to the growth of Oak, but which, from its nearness to the sea—about ten miles as the crow flies—fails to produce, except in very deep narrow gills, other than short stumpy trees with bushy boughs, evidently thrown out as a protection against the south-west wind. These trees produce knotty and unsaleable timber. About thirty or thirty-five years ago, the planting in St. Leonard's Forest was begun with Larch and Oak, the proportion being about five of Larch to one of Oak. Since the Larch were seven or eight years old, they have been gradually thinned out, and, though in no case have they thoroughly disappeared, the land is fairly planted with straight-grown silver-rinded Tellars, which bid fair, in due time, to become a fine Oak forest. This land is ordinary forest land.

Effect of the Periodical Cutting of Underwood.

The periodical cutting of underwood affects the growth of trees, as it affords the only opportunity of thinning woods; thus the thinnings are at longer intervals than, perhaps, is best for the growth of Oak timber. The custom in the Wealds of Surrey, Sussex, and Kent, is, to cut the underwood at intervals of from eight to twelve years. Underwood is usually sold by auction in November, and in the following spring the Oak trees are inspected, and such thinning as is required is then done. If the timber only was considered, a shorter interval of, say, five or six years, would be better, but as the underwood is an important portion of the profits, it is impossible to make the most of it until it becomes large enough for conversion into Hop-poles, hoops, &c. As to the age at which the timber causes injury to underwood, supposing there is a full plant of Tellars at any given fall, for the next two cuttings (say, for twenty years), there will be little difference found in the value of the underwood, which averages from £8 to £10 per acre. The next three cuttings will be reduced, on an average, about one-half, and, afterwards, the periodical cutting will be sold for a very small sum, viz., £1 to £1 10s. per acre, which will not pay for rates, fencing, and ditching.

Pruning Oak Woods.

Not only is pruning unnecessary—for, if thinning is done gradually, allowing the Oak trees to draw each other up to such height as may be required, the lower branches will of themselves drop off—but it is actually injurious, as every timber merchant or village carpenter knows. And the boughing of Oak trees materially affects the value of the timber when felled, though the tree, when pruned, may be only twenty or thirty years, and, when cut, 150 years old. When the boughs are thrown off by nature, as they are most perfectly under careful management, the bark gradually closes over the part from which the bough dropped, and it becomes impossible to define the former position of the bough, nor would any sign of it be found when the tree is cut; but, should the tree be pruned, an unsound knot, or a sore in the tree, is at once formed, allowing the water to penetrate the trunk where the branch was cut off. This will rot, and a black dead piece of wood will be found in the centre of the tree when it is cut. The bark will, no doubt, usually close over the wound made; but this will take some years, and, before it is closed, the mischief will be done; and, in old trees, it not unfrequently happens that the perfect closing over the wound by young wood causes a species of dry rot.

Thinning and Clearing.

As I stated above, the time for thinning woods is when the underwood is cut. The greater part of the timber of the weald in question is grown with underwood. The underwood is cut, on an average, once in ten years. At each cutting, trees which have attained a good size, and show symptoms of diminished growth, are felled, and

open spaces are thus obtained for a fresh crop. The same opportunity is taken for thinning the young Tellars, and of saving such further young plants as have come up since the last cutting of the underwood, that is, ten years previously. In thinning Tellars and young trees, it is of the utmost importance that the leading trees should be left, and the inferior ones cut. For the ultimate crop the trees should stand from 20 to 30 feet apart. The great aim of every forester should be to keep the trees thick enough to draw each other up to the height required, so as to have a clear stem of from 20 to 40 feet, as the case may be, and so to gradually thin them as not to abruptly admit the wind, and thus cause them to be checked in growth. Any checking of growth is speedily detected by the throwing out of a quantity of "rushy" boughs, as they are called. We have now carried our wood up to the age of from seventy to eighty years. If the trees have been properly managed, little further thinning will be required until their clearing, unless the timber is left for a longer period than 100 years for large shipbuildings. After a wood has been cleared of a natural crop of Oak, and the underwood has grown for a period of ten years, it will generally be found, at the next cutting, that a good crop of self-sown Oak Tellars is fairly scattered over the ground. The Tellars are usually marked with paint, and are excepted from sale. At this first cutting the young Oak trees will be about the same height as the underwood; and, if the underwood is fairly good, the chances are that it will be unnecessary to thin the Tellars at all, more than by a woodman going round and chopping down with a hatchet any inferior trees. During the next five or six cuttings the real work of thinning must be executed.

Profits.

I now come to the question of profit, whether timber or underwood pays best, taking a certain period of time, say, 100 years. Assume an acre of underwood of a fair average description in Kent, Surrey, or Sussex, no Oak trees being allowed to be grown upon it, but kept entirely for underwood. I will suppose that it has a good set of stems upon it. This underwood is worth, to sell, upon an average of £10 per acre at ten years' growth; and it may be assumed, for the purpose of rental value, that underwood selling for £10 or £12 per acre, is worth the same number of shillings rent; this will be found a close approximation if worked out. This acre of woodland will therefore produce a rent of 10s. per annum, and go on producing the same description of underwood for the 100 years with occasional filling up. Take, secondly, an acre of woodland under similar conditions with regard to underwood, but allow Tellars to grow upon it; there will be found little or no difference in the value of the underwood for the first twenty years. During the next forty years the underwood will have diminished in value; but we may fairly calculate that the trees which have been cut in the course of thinning, after twenty years, will have made up any loss in the value of the underwood in this period. In fact, the produce is much more than enough to make up the loss of profit from underwood. For the remainder of the 100 years, the underwood will pay very little, and the thinnings will not produce more than enough to pay expenses. In the foregoing observations, I have assumed that underwood sold at £10 per acre is worth a rental of 10s., and that for sixty years the underwood and Tellar thinnings together will produce fully 10s. per acre. From the latter period and up to 100 years, when I assume the timber will be fit for felling, little or no revenue will be derived. The rental of 10s. per annum accumulated for forty years at 4 per cent., gives, in round figures, £50 per acre. The following is an instance of a wood of 4 acres near Reigate, which was planted in 1830 with Oak and other trees. I have no record of any thinnings prior to 1866. In April, 1866, twenty-eight Oak trees, containing 111 feet, and 208 Tellars, were cut and sold for £42. In April, 1872, thirty-nine Oak trees, containing 216 feet, were cut and sold for £21. In 1873, seventy Oak trees were cut which were valued at £40. This wood was sold, and the timber on it valued very accurately, in 1873. There were 375 Oak trees, containing 2,600 feet of timber, and a few other trees, valued together at £247; being at the rate of £60 per acre. The above sum of £60 per acre gives a rental of 11s. per acre at 4 per cent., and beyond that, of course, is the sum of money received for the thinnings. The trees in this wood will not require much more thinning. It is, I think, apparent that the Oak-growing districts, in which underwood and timber are grown together, produce a much larger profit on an average of 100 years, than it is possible for Oak plantations alone to produce, as, during the earlier periods of growth, underwood pays an income when the land planted with Oak pays nothing.

Parchment Labels—Labels for plants, that have to be packed in any moist material, should never be written on parchment, as the moist heat frequently renders them illegible.

* An abstract of a paper read at an Ordinary General Meeting of the Institution of Surveyors, February 16th, 1874.

WORK FOR THE WEEK.

PRIVATE GARDENS.

The Flower Garden.—Owing to the open weather which we have had, this department is, just now, unusually gay. Of Primroses and other early spring flowers, exclusive of bulbous plants, the variety in bloom is considerable. Snowdrops and Crocuses are blooming freely in borders and on lawns, a fitting place for them, and where they will be succeeded by Dog's-tooth Violets and Scillas, so that all will be past before Grass-cutting recommences. The replenishment of flower-beds from the reserve stock must now occupy attention; all spring-flowering plants may be transplanted with impunity according to convenience. Several of the autumn-sown annuals, too, may be transplanted from their winter-beds to where they are required for blooming, and to fill up vacancies between perennials. Hollyhocks and Foxgloves from last year's sowings should now be transplanted permanently in good rich soil; indeed, a spadeful or two of well-decayed manure mixed with the soil in each hole is an important addition. Ivy, Jesamines, Clematises, Honey-suckles, Roses, Cratæguses, Magnolias, and similar plants on walls should be thinned or pruned, if necessary, and neatly trained. Form edgings of the variegated Queen of the Meadow, Arabis, Cress, Polemonium, Grasses, Daisies, Golden Feverfew, Euonymus radicans, Santolinas, &c. Some of these, such as the Golden Feverfew and Cress, are only fit for spring gardening when saved from the previous year's sowings, and should be replaced again in April or May from spring-sown plants, which do not so readily run to seed during the summer and autumn months. Various kinds of flower-seeds should now be sown for early blooming; but the main crop of hardy annuals is best sown in the first week of April.

Sub-tropical Plants.—Sow seeds of *Acacia lophantha* on a brisk hot-bed, and prick off and pot singly the young seedlings as soon as fit to handle. Prune back old plants, and permit them to start slowly in a pit or greenhouse. These have a fine effect in the sub-tropical or flower garden mixed with flowering-plants or used in clumps in the centres of beds. Sow *Solanums*, *Wigandias*, *Ferdinandas*, *Abutilons*, *Sonchuses*, &c., in pots of sandy soil in brisk hot-beds, afterwards to be pricked off and potted as they require it. Old plants of the same that were saved from last year's collection should be forced in a pit or hot-bed in order to induce young growths for cuttings. Sow Castor-oil plants, Tobacco plants, Hemp, Uhdeas, Chilian Beet, Amarantuses, variegated Maize, and a few others in brisk heat, and attend to them as regards timely thinning, pricking off, potting, and watering; grow them on in a warm temperature for a time, and, towards the end of April, or in May, gradually harden them off prior to planting, which should be done in June. *Erythras* may now be started gently, and, if required, the young shoots may be used as cuttings; these will make nice little plants by May or June, and next year they will bloom well. Propagate *Aralia papyrifera* by means of root cuttings, but do not start the old plants into growth until next month. Plants of *Aralia japonica* raised from seeds last year will make fine plants for bedding-out next summer, provided they are grown on slowly, as, for instance, in an intermediate house. Sow a few more seeds in a sandy peat or loamy soil, in gentle heat, and propagate by means of cuttings obtained from the old plants, inasmuch as a stock of this sort cannot be obtained from roots, as in the case of *A. papyrifera*. *A. spinosa*, a showy and pretty plant, is hardy, and only requires pruning back to a plump eye in March or April. In the case of frosty weather, however, the ground containing the roots should be mulched, and the stems encircled with straw or hay-bands. Cannas may be started into growth like Dahlias; and, when they begin to grow, they may be divided into as many pieces as there are shoots, on each of which a piece of the old root should be retained. Canna seeds may be sown in a hot-bed or pit; and, if they are steeped for a night in tepid water, putting them into it when it is at a temperature of 140°, they will germinate sooner than they otherwise would do. If the stock of *Caladium esculentum* is short, start some roots, and propagate every offset as a cutting. Propagate *Ficus elastica*, by means of cuttings or eyes, with a leaf attached to each, and held upright by means of a wooden peg. Cuttings of *Melanthus major*, struck now, make fine plants for next summer's use. New Zealand Flax, both green and variegated, may be divided, and each division potted separately in a loamy soil, and plunged in a gentle bottom-heat. Plunged or planted in flower-beds, they are very effective, and old specimens are most in place isolated on lawns or as centres to beds. The general stock of Cycads, Palms, Musas, Bamboos, Ficuses, Dracænas, and other perennial tender sub-tropical plants, will now be starting into fresh growth; therefore, such as require fresh potting should be attended to in that respect, so that the plants may form a good supply of fresh roots before summer sets in. Hard forcing should not be practised in the case of those not potted, a slow and hardy growth being best.

Plants for Carpet-bedding.—As carpet-bedding continues to be so fashionable, some forethought must be exercised as to the quantity of plants of the various kinds that are likely to be wanted. Foremost among these will be *Alternantheras*, which will be required to be now subjected to a strong moist temperature to cause them to grow, when abundance of cuttings that strike freely may be obtained. Highly-coloured shoots do not strike so freely as green ones, which, afterwards, become coloured; seeds of Golden Feverfew should now be sown in a hot-bed; last year's saved plants are sure to "run" during the summer, therefore, this plant is always best treated as an annual. Sow seeds of *Lobelia pumila*; and, also, propagate it by means of cuttings; its compact habit and bright blue flowers make it very valuable for carpet-bedding. The variegated *Mesembryanthemum* should be increased by means of cuttings; this plant, although hardier than most greenhouse plants, thrives well, and does not lose its compact character, in a stove. *Ajuga reptans sanguinea*, a good dwarf plant, furnishes a dark bronzy colour, and may be propagated in cold frames or out-of-doors by means of offsets; but more readily in heat. All dwarf *Echeverias* are useful for this purpose, and may be kept in boxes in a cool-house or frame, and near the light, rather dry at present, and perfectly free from all decaying matter. The young plants raised from seeds, offsets, or leaves, are best grown in a gentle heat, in order that they may be strong by bedding-out time. Various kinds of *Sempervivums* and *Sedums*, both tender and hardy, may be treated in the same way as the *Echeverias*, but in the case of the hardy ones, unless increase of stock is necessary, they are best wintered out-of-doors. *Coleuses* and *Iresines* are, also, useful for forming central masses to the beds, and if a few old plants were saved to produce cuttings, these should be started into growth at once, and their propagation proceeded with, because well hardened off young plants are much more desirable than old ones. *Centaureas* have a fine effect used with dark-leaved plants, therefore, have a stock of them for that purpose, either raised from cuttings in the autumn, or from seeds or cuttings now. Keep old plants pretty dry, and in cool airy pits. The variegated *Thymes* make fine edgings or carpets, and can now be raised freely from cuttings, or by means of division. The *Santolinas*, too, may be readily propagated by the same means, and, as they submit to severe clipping in summer, they are very useful for this kind of work. They may, also, be increased freely by means of division in the open border. An old white variegated *Pelargonium*, called Dandy, is of such dwarf habit as to be very suitable for this purpose; but, although it strikes freely from cuttings, these are twelve months old before they make much show. There are many hardy plants that can be used for this purpose, such as the Mossy Saxifragas, the Creeping Veronicas, *Pyrethrum Tchatchewi*, the variegated *Arabis albida*, and several others, besides a few such as *Polemonium cæruleum variegatum*, that form nice specimens when studded here and there in the carpet.

Roses.—Roses on pillars, walls, or trellises should have any dead wood about them removed, the very long living shoots shortened, and the whole neatly re-tied to their supports. A few Roses in beds and borders may be pruned to induce early blooming; but the general pruning had better be deferred for a short time yet. The pruning of hardy Roses, particularly those on the Manetti stock, however, may be done now, as they begin to grow early. Suckers and gross growths should be removed from all sorts, and stakes applied to such as require them.

Making Hot-beds.—These must now be made at once for the propagation of bedding plants, starting stove and greenhouse plants into growth, and for producing a few early salads and vegetables. Stable-manure that is moist throughout, and which has been turned once or twice, may be used alone, but in this case the heat is violent, and only of moderate duration. Stable-manure mixed with a fourth of cow-manure makes a good hot-bed, and one that retains its heat longer than one which consists wholly of stable-dung. The latter mixed with tree leaves—Oak leaves, if obtainable—makes excellent hot-beds. Even damp tree leaves alone, once or twice turned, form a good bed, and one that retains a moderate and steady heat for a long time, but a greater bulk of material must be used in this case than when litter is mixed with the leaves. Tan, spent Hops, and rope refuse, too, make good hot-beds, but they must be used in pits, either out-of-doors or indoors, or they will not hold together. In making a hot-bed, form a foundation about 2 or 3 feet wider than the dimensions of the frame to be set on it. This will give a good space for linings outside the frame. All hot-beds, particularly those of large size and depth, made above ground, should have a foundation of rough open material, such as a layer of brushwood; over that may be put Asparagus, Bean, and Pea haulm, and then the fermenting material, the whole being firmly put together. The size of the beds will differ according to the heat they are required to produce, and the plants to be forced on them. As to the time when they should be put up, that depends

upon what they are intended for. The beds, though firmly built, will sink considerably, consequently some spare material must be preserved for making up the linings, so that the proper temperature may be maintained. For some weeks after being put up, a vigilant watch must be kept to see that the beds do not become over-heated, and thus burn both roots and seeds placed in them. The temperature of such beds may easily be determined by means of sticks thrust into them in various places, and kept there, drawing them out occasionally, and feeling them with the hand; or thermometers may be employed for the purpose.

Orchids.—Of *Odontoglossums*, *Sophranitis*, *Lælia anceps*, and some others there is now a fine display, and, if kept at the coolest end of the house, their beauty will be retained longer than it otherwise would be. A general overhauling and re-potting of the several species should now take place. Before potting, however, withhold water for a few days, in order that the roots may be more easily freed from the old soil. *Miltonias*, *Dendrobiums*, *Bletias*, *Brassias*, *Cyrtopodiums*, &c., should be potted as they begin to grow; while *Cattleyas*, *Angræcums*, *Saccolabiums*, *Vandas*, and *Aërides* should be potted before they start into growth. *Calanthes*, when they fairly show signs of growth, should be re-potted. For epiphytal Orchids, the pots or pans used should have a small pot inverted over the hole in the bottom, and then they should be filled up with broken crocks and charcoal to within 3 inches of the top; terrestrial Orchids require less drainage. The former require only a spongy material, or compost consisting of fibrous peat and *Sphagnum*, which should not be pressed too hard. The latter require soil of a more nutritious character, such as turfy loam, leaf-mould, or peat, and rotten horse or cow-dung. Water must be carefully or rather sparingly given at first. Some will require fresh blocks, and those found to do better on blocks than in pots should be supplied with them. Orchids in general seem fond of non-resinous woods; therefore, Cork, Apple, Pear, Plum, and Maple blocks are more suitable than those of Deal or Pine wood. Some kinds grow best in baskets, a supply of which must also be got in readiness for them. Place some roughly-broken crocks in the bottom, with rough peat and *Sphagnum* on the surface, to firm the plants. Over such Orchids as *Phalænopsis*, that have lost their crowns, place a small board supported on pegs so as to prevent drips from falling on the plants and rotting them.

Hardy Fruit Garden.—All standard fruit-trees should be pruned before this time, and their trunks and main branches cleared of Moss and Lichens. Prune and nail wall fruit-trees, if not already accomplished; and, with glass or wooden coping, Frigi Domo, canvas, or fishing or woollen nets, protect Peach and Apricot blooms, when expanded, from frost. Whatever protection, other than a coping, is used should be affixed so that it may be easily lifted and let down as required. Young trees may yet be planted, and any old ones intended for transplanting next autumn should have their roots cut now, by which means they do not suffer nearly so much in removal as they otherwise would do. Prune back to 15 inches above ground stocks on which grafts are to be put. Mulch the roots of lately-planted trees, and affix strong stakes to all that require support; see, also, that espaliers are sufficiently staked and tied. Have all trees on walls properly pruned and nailed, as the flower-buds are more than usually forward this spring. A good syringing with sulphur and water well mixed will be found very beneficial to wall-trees. Make new Strawberry plantations, and fill up empty spaces in old ones; remove all runners, dig between the rows, and apply a good mulching of litter between the rows on the surface of the soil. Collect all prunings and other rubbish and burn them, saving the ashes and likewise the charcoal resulting from the operation for manurial purposes. The prunings may be advantageously used in burning clay for applying to stiff soils, in order to lighten it and to render it porous.

Irrigation a Danger.—Irrigation is, no doubt, a most desirable thing for India; but it would appear to be quite possible to have too much of it in particular places, judging from a resolution recently published by the Government of Madras on the prevalence of fever in the Godavery Delta. The Governor in Council observes in this document that the deplorable condition of the district, as sketched in a report presented to him by two civil officers specially deputed to inquire, is mainly due to "the utterly inadequate means of drainage in a country whose swampy nature has been aggravated by the great system of irrigation works." He directs accordingly that the subject be forthwith earnestly taken into the consideration of the Public Works Department, and arrangements be made with the least possible delay for "remedying this most crying evil, whereby at present the gift of financial prosperity bestowed upon the district is coupled with the curse of disease."

THE HOUSEHOLD.

AMERICAN CRANBERRIES.

THROUGH the kindness of Messrs. Carter & Co., of High Holborn, we have received a box of American Cranberries from the New Jersey Cranberry Growers' Association, accompanied with a request that we would report on their culinary value, and state the condition in which they arrived in this country. The Cranberries are much larger and finer than those we are accustomed to see, being the produce of the *Oxycoccus macrocarpus*, and not the species indigenous to Europe, namely, the *Oxycoccus palustris*. They were sent in small boxes containing about six or seven pounds each, and were not bruised or damaged by the transit. The production of Cranberries in the United States, although necessarily confined to limited areas—as they grow in turfy soil, and the cultivation is attended with heavy expense—has increased within the last few years to a surprising extent, as has also the taste and demand for them. About twenty-five years since, the earlier cultivators were thought to be making rash experiments, and it was feared that a crop of one hundred barrels would overstock the market; but now a capital of millions of dollars is successfully employed in their growth, and the annual yield is estimated to be about one hundred thousand barrels—a large part of this amount being produced in Southern New Jersey. In the United States they are regarded as supplying a place that can be filled by no other fruit, as they keep well if stored in a cool dry room, and can be prepared for use in a short time and with little trouble. The great American Cranberry dish is Cranberry sauce, which is used as a preserve with bread or in pastry, or as an adjunct to meat, game, and poultry, as we employ Currant jelly. It is made in less than ten minutes, by stewing the berries with sugar and a little water. Sometimes the berries are strained after boiling, to remove the skins and seed before the sugar is added. As prepared in either of these modes, the American Cranberries have a piquant acid flavour, perfectly *sui generis*, the recollection of which makes us regret the fact that, at the present time, they are not to be obtained in England. We also tested the fruit in pies and tarts made after the English fashion, and found it most excellent. The Americans have a household method of sealing up their preserves in air-tight glass jars, which are not to be obtained in this country; therefore, we tried the Cranberries in the form of jam; but the amount of boiling necessary to reduce the fruit to a solidity fit for keeping dissipated the flavour to a considerable extent. The strained juice furnishes a very admirable jelly, of an exceedingly rich colour, and perfectly transparent. We had not an opportunity of trying all the American recipes with which we were furnished; but, from the experience we have had, we feel confident that the New Jersey Cranberries only require to be known in this country to be very highly appreciated.—*Field*.

Quinces as an Addition to Apple Tarts.—Lady Llanover directs as follows:—Cut the Quinces in quarters. To 5 lbs. of fruit put 3 lbs. of sugar, and half a quarter of a pint of water. Put them in pint jars; put plates or saucers over the jars, and let them simmer very gently for three hours, placed in boiling water: put the peels in with them, and take them out when done; the overplus of syrup may be bottled, and also used to flavour tarts. It will prevent waste of sugar if the peels are stewed the first hour without sugar, then take out the peels and add the sugar, and simmer for two hours longer.

NOTES AND QUESTIONS ON THE HOUSEHOLD.

Indian Corn in England.—I observe you say that we should have no trouble in raising plenty of this in a green state for cookery. You are right; on warm soils, everywhere in the south of England, it ripens well; it used to ripen regularly in the herbaceous ground at Kew, and from Kew-grown seeds.—T. S.

Worcester Sauce.—Allow me to furnish your correspondent (see p. 102), with a recipe for making this sauce. I do not offer it as Lea & Perrins, but I do say that it is equal, if not superior to it, in my opinion. It is not a recipe copied out of a book, but one I have known a long time. Half-a-pound Shallots, 1 oz. Pimento powdered, $\frac{1}{2}$ oz. Mace powdered, $\frac{1}{2}$ oz. cayenne, half a Nutmeg powdered, $\frac{1}{2}$ lb. anchovy fish, 1 oz. salt, 3 pints of vinegar, 6 oz. soy. Chop or bruise the Shallots, beat up the anchovy fish, mix all together, stand for a month or two, and lastly strain through a coarse sieve.—C. I. B.

Bamboo Grain as food.—Those who like Bamboos for their graceful appearance, may be interested to know that they, like so many of the Grasses, are food-givers. Mr. Blechynden, in a letter published in the *Journal of the Agricultural Society of India*, gives particulars of the service rendered by this grain after failure of the Rice crops in Orissa in 1812, when a general famine was apprehended:—"The grain obtained from the Bamboo was most plentiful, and gave sustenance to thousands; indeed, the poorer, and therefore the greater, portion of the inhabitants subsisted for some time solely on this food. So great was the natural anxiety that was evinced to obtain the grain, that hundreds of people were on the watch day and night, and cloths were spread under every clump to secure the seeds as they fell from the branches."

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 18TH, 1874.

At this meeting, Orchids were well represented, and some choice kinds were staged; Cyclamens were finer than we ever remember to have seen them in small pots, and other winter-flowering decorative plants were, also, shown in fine condition. Messrs. J. Standish & Co., Ascot, furnished an interesting collection of forced shrubs, Lily of the Valley, Cyclamens, and other decorative plants, well grown and profusely flowered. Amongst these were some well-grown Bouvardias and half-a-dozen plants of the white-blossomed Abutilon Boule de Neige; this last furnishes quantities of snowy bell-shaped flowers during winter, and, together with the smooth glossy-leaved Clematis indivisa, deserves general cultivation for the purpose of yielding cut flowers; this Clematis bears white star-shaped flowers, about the size of a crown-piece, and, judging from the small specimens of it exhibited, it is a profuse-flowering species. One of the most useful plants shown in this group was the green feathery Asparagus decumbens, sprays of which are useful either for wreaths or bouquets; it grows well in small pots, or it may be planted out and trained up a trellis. From Mr. R. Dean, of Ealing, came a splendid group of seedling hardy Primroses, amongst which were some very bright and showy varieties; these are well suited for early spring bedding, or for growing in pots for greenhouse or cool conservatory decoration. When grown in cold frames, their flowers and foliage come much brighter and better in every way than when exposed, and they well deserve the extra protection, although they do not absolutely require it. Some seedlings, the result of a cross between *P. altaica* and *P. vulgaris auriculæflora*, showed a marked improvement, their flowers varying in colour from rich mauve to deep violet purple. The same exhibitor also staged a small collection of Violets, including Lee's new variety, Victoria Regina, an evident improvement on the Czar, and, like that variety, it bears large purple flowers, very sweetly perfumed. Mr. H. B. Smith, Ealing Dean Nursery, contributed a very even collection of double Chinese Primulas, of vigorous habit, bearing stout trusses of rosy salmon-tinted flowers. Mr. C. Turner, Slough, staged a collection of scarlet, salmon, and rose-flowered Zonal Pelargoniums, and an excellent collection of standard Aucubas remarkably well fruited. The last named are especially adapted for the winter decoration of cool conservatories, or even ordinary apartments, and should be more generally cultivated in private gardens for these purposes than they are. Clusters of the bright scarlet berries and handsomely mottled foliage come in very usefully for church or domestic decorations of all kinds. From Messrs. Veitch & Sons came the best plants of Cyclamen persicum in 48-sized pots that have been shown this season. They are vigorous and well-flowered, each plant producing from four to six dozen blossoms, the colours being bright and distinct. The same firm also exhibited a collection of Amaryllis, among which the following varieties are specially worthy of cultivation; *A. Ackermanni pulcherrima*, a fine flower, of the most vivid velvety-crimson; *Le Zouave* bright reddish-crimson, mottled with white; Spotted Gem, white, speckled with vermilion; Ariadne, white, heavily streaked with deep crimson; Leopold, a very fine widely-expanded flower of a creamy-white, the lower portion of each segment being of a rich maroon-crimson. In the same collection we noted a well-flowered specimen of *Toxicophlæa spectabilis*, a white-flowered shrub, from the Cape. The bark of this plant is very poisonous, and is sometimes used by the natives for poisoning fish. From Messrs. W. Paul and Sons came a fine collection of Camellia blooms, very prettily staged in boxes of fresh Moss, in the same way as Roses are shown. The best reds were—Bealii, Eximia, Reine des Fleurs, Sarah Frost, Jeffersonii, and Imbricata; amongst the whites Fimbriata, Monteron, Candour, and Alba elegantissima were specially noticeable. The same exhibitors also staged a box of their new Chinese Primula—Waltham White. It is of stout habit, and bears large white flowers of good substance; the foliage, however, lacks the fresh greenness so essential to this plant, and the purity of the flower itself is marred by a greenish-yellow eye; still, for hybridising purposes, it is invaluable. Mr. W. Bull furnished some striking novelties, several of which obtained first-class certificates. Among these we noted *Hippeastrum picturatum* (*Amaryllis vittata* var.), with long flowers something like the new *Lilium Phillipense* in form, of a creamy-white colour heavily streaked with crimson. It bears seven or eight flowers on a spike, and is so distinct in form and colour as to merit general cultivation. Another variety *A. Sultana*—bears crimson-striped flowers on scapes 2 to 3 feet high. A considerable number of Orchids were exhibited, and contributed much to the interest of the exhibition, especially as several novelties made their appearance for the first time. One of the most striking plants staged was a seedling

Dendrobe (*D. Ainsworthii*), raised by Mr. W. Mitchell, gardener to Dr. Ainsworth, of Lower Broughton, near Manchester. This is the result of a cross between *D. nobile* and *D. heterocarpum*, and combines the habit and general characteristics of both species. Mr. J. Child, gardener to Mr. Torr, Garbrand Hall, Surrey, staged a fine plant of *Cœlogyne cristata*, rather past its best, and was awarded a cultural commendation. Mr. B. S. Williams staged a small plant of *Renanthera coccinea* in flower. This is one of the most beautiful of Orchids, but one of the most difficult to bloom regularly. The plant shown had been grown in a Cattleya-house, and had made very stout and vigorous growth. The same exhibitor also staged *Vanda tricolor*, *Cœlogyne cristata*, *Masdevallia Tovarensis*, *Oncidium cucullatum*, and a good variety of *Dendrobium nobile* in fine condition. Messrs. Veitch contributed a nice bank of these plants, including good examples of *Ada aurantiaca*, bearing rich orange-tinted flowers; *Angraecum citratum*, bearing a gracefully-arched spike of creamy-white flowers; a new species of *Dendrobium*, intermediate between *D. crassinode* and *D. crystallinum*, in growth and flower; and some very beautiful and distinct varieties of *Odontoglossum Alexandræ* and *Lycaste Skinneri*. Mr. E. Bennett, of Hatfield, furnished half-a-dozen dishes of Apples and Pears, in fair condition; and four remarkably well-grown Smooth Cayenne Pines came from Her Majesty's gardens at Frogmore. Vegetables were limited in quantity, the most important being a collection of ten varieties of Potatoes. These were mostly of American origin and growth, and were staged by Messrs. Carter & Co., of High Holborn.

First-class Certificates were awarded to the following:—

Seedling Primrose *Violacea* (R. Dean), robust habit, fine fresh green foliage, and a profuse bloomer, colour rich violet-purple.

Primula Prince Arthur (F. Perkins), a vigorous sturdy-habited variety, bearing trusses of double flowers of a rosy-vermilion tint.

Toxicophlæa spectabilis (Veitch) a useful flowering greenhouse shrub, bearing dense clusters of pure white Jasmine-like flowers in dense axillary clusters.

Angraecum citratum, a rare and beautiful Orchid, bearing spikes of creamy-white flowers nicely perfumed.

Hippeastrum picturatum (*vittatum*) (Bull), a beautiful free-flowering stove bulb, having white flowers striped with reddish-crimson.

Rapatea pandanoides (Bull), a curious plant allied to the genus *Juncus*. It has peculiar sheathing bases to its strap-shaped foliage, and deserves cultivation as a novelty.

Alsophila elegantissima, a very graceful stove Tree-Fern having very elegant shining divisions to its fronds.

Pleocnemia Leuziana, a beautiful stove Fern, having finely-divided broad and spreading fronds.

Dendrobium Ainsworthii (Mr. W. Mitchell), a new hybrid Orchid, the result of a cross between the old *Dendrobium nobile* and the violet-scented *D. heterocarpum* (*aureum*). It is distinct from either parent, although partaking somewhat of the character of both. Sepals and petals, creamy-white; lips, fully expanded, white, with a vinous purple or claret-colour blotch.

BOTANICAL SOCIETY OF EDINBURGH.

At a meeting of this society, which took place the other day, Mr. McNab communicated a notice of the Lochwood Oaks in Annandale, Dumfriesshire. These Oaks were probably not less than 500 years old; their stems were from 9 to 14 feet in circumference, and the trees were from 30 to 50 feet in height, with an average spread of branches of 60 feet. All the trees were in a decayed or decaying condition, and were covered with evergreen Ferns, which gave the wood in winter a wonderfully beautiful appearance. In his report of the open air vegetation in the Royal Botanic Garden, Mr. McNab stated, that owing to the mildness of the season, the number of species of selected plants in flower greatly exceeded those noticed at any previous February meeting of the society. Since January 8th, the thermometer had been fourteen times at or below the freezing point. During the early part of February, flowering specimens of 132 species and varieties of trees, shrubs, and herbaceous plants were picked in the open air—all of which were shown to the society. Of these, 76 might be considered as summer and autumn plants, while the remaining 56 might be looked upon as winter and spring-flowering varieties. The frost experienced since the 9th—the lowest being on the night of the 14th, when the mercury stood at 15° below the freezing point—had injured a large proportion of the premature flowers. This frost will be much against the blossom of many fruit trees, particularly the Pear, which is now in a very advanced state.

THE obituary of the *Times* of last Monday contained a notice of the death of the daughter of the once well-known Dr. Darwin, philosopher, and author of "The Botanical Garden." She died in her ninety-first year, and was probably the last link between us and a society of provincial celebrities to whom the progress of British industry has been enormously indebted. Her father was a prominent member of the well-known "Lunar Society," so called because of the day of meeting, that of the full moon, to enable the visitors to see their way the more clearly home in the evening. Among its members were Watt and Boulton, of steam-engine celebrity; Wedgwood, the father of British pottery; Priestley, the chemist, and many others of little less note. The lady just deceased had made tea in her youth for all these celebrities, and her memory of past times remained wonderfully clear. Her own grandmother, with whom she lived as a girl on most affectionate terms, was born in the year that Queen Anne died.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FIGS.

By J. R. PEARSON, Chilwell.

THOSE who know what a delicious fruit a really ripe Fig is are often astonished that Figs are not more grown in this country than they are. Here is a fruit-tree which will produce two, and, indeed, sometimes three, crops in a season of such wholesome fruit that persons who are subject to gout can eat them without injury; and yet we hardly ever see them fit to eat. How is it? I think it is because few persons know what a good Fig is. I have never grown Figs as I could grow them, and yet have given fruit to people, who have just said they did not like them—(indeed, some have used stronger language, and said they hated them)—and heard them say, "Oh, the Figs I have tasted before were not at all like these!" How is it? The likely fruit produced on a back wall of a Vinery, shaded, as they must be by the Vines, can be good; and yet any place, where nothing else would grow, has been thought good enough for Figs. Then, again, many of the best Figs are almost unknown. The Royal Horticultural Society did great good lately in growing an immense number of Figs in pots; and, under the clever management of their talented gardener, Mr. Barron, these were so good that a just opinion of their merits could be formed. It is much to be regretted that a most injurious kind of small scale insect, very difficult to kill, was introduced from the Continent, which put a stop to this interesting work. Still, a great deal of useful knowledge was obtained. But, to grow Figs as they can be grown, the plan adopted by Mr. D. Thomson, of Drumlanrig, must be followed, and the trees trained under glass, like Vines; then, with the full advantage of sunshine, people will know what Figs really are. I am so sure that Fig culture is only beginning, and must extend to a degree of which few persons have an idea, that for some years I have been trying all the kinds I could procure, to see which were really worth growing, and have now a house, a hundred feet long furnished with bearing-trees. I shall certainly discard many kinds I often hear praised, and keep only the best varieties. As it is useful to all fruit-growers to know which are the best, I will say that up to the present time no kind I have fruited is at all equal to Bourjassotte Grise, a good grower, great bearer, and producing large fruit; it has one peculiarity, it is always good. Now, almost any Fig, when at its best, that is, when fully ripened, and with a drop of honey hanging from its eye, is good, but this variety is always good, and, when at its best, better than any other kind ever is. This kind was introduced by the Royal Horticultural Society, as new, a few years since, and is as great a favourite with Mr. Barron as it is with me; but, under another name, it has been long grown at Clumber, where a large old tree is, or was, lately covering a great space on a back wall of a Vinery. Even in this unfavourable situation its good qualities were recognised by Mr. Moffat, who gave cuttings to his friends. This will account for my having plants 8 or 10 feet high, whilst in Mr. Rivers's catalogue it is placed amongst the unproved kinds. Thinking so highly of it, I sent it to Chiswick, and Mr. Barron sent me, in exchange, what had proved the best variety in his collection, and we then found they were the same kind, when both produced fruit. There is another kind which is generally described as a nice, but not highly-flavoured, Fig, which my experience places amongst the very best when well grown, and that is La Madeleine or Angélique, for it has two names—indeed, several. Dr. Hogg says when well ripened it is of good quality. I venture to say when better ripened he will find it exquisite; with me it has been almost transparent, and quite golden in colour. When I have proved all the varieties I have, I intend, if I live, to plant a house on Mr. Thomson's plan, having planted my new seedling Vines in my present Fig-house. I intend to discard the following kinds:—Castle Kennedy, as a bad bearer; Datte, because it drops its fruit so much before coming to perfection like the last named; Early Violette, too small; Ciel de Perdrix, too small; Panachée, not rich, too late, and not a good bearer.

THE SECRETARY OF THE ROYAL AGRICULTURAL SOCIETY ON THE RECENT ESSAYS AND PRIZES.

SINCE the publication of the decision of the judges appointed by the Council of the Royal Agricultural Society of England, to examine and report upon the essays sent in to compete for Lord Cathcart's prize of £100 for the best essay on the "Potato Disease and its Prevention," several letters and articles on the subject have appeared in the agricultural and horticultural newspapers, some of them referring also to the subsequent action of the council. While the matter was still under the consideration of the council, I refrained from making any statement in reference to the questions at issue; but now that the council have decided upon their course of action, I should like to be allowed to explain the reasons which influenced the judges in recommending the council to take the course which eventually was adopted. Amongst the ninety-four essays which came before the judges, there were several, the writers of which averred that the only way to prevent the Potato disease was to plant certain sorts (named or described in each case), which the writers of the essays had found, by experience, to be successful in this respect—that the disease did not attack them. These Potatoes were, in fact, asserted to be "disease-proof," although all the writers did not use precisely that expression. Now the judges had no reason to doubt the good faith of the essayists who made these statements; but, at the same time, it was impossible to award the prize on the mere belief in the good faith of the essayists, and on the probable truth of their assertions, so far as their experience had gone. Then, as there were several kinds of Potatoes put forward by different essayists as possessing the disease-resisting property, it was impossible for the judges to decide between them without trial, even if they had been thoroughly convinced by means of indisputable evidence that these varieties of the Potato had been proved to resist disease for a sufficient number of years in succession, and in a sufficient number of different districts having the requisite variations of soil and climate. They, therefore, recommended the council to give the possessors of the various kinds of Potatoes, said to have the property of resisting the disease, the opportunity of getting them and their produce tried for three years in succession in twenty different districts of the United Kingdom; and to give a prize of £100 to the early and late variety respectively, which should not be attacked by the disease in any one year on any one experimental plot, and which (if more than one fulfilled this condition) should have the best cropping, keeping, and cooking qualities. The council have not only agreed to do this, but they placed an additional £100 at the disposal of the judges to divide amongst those who may be second, or second and third, in the race, in either class, provided that the essential requirement of resisting disease is complied with. It is not, however, to be inferred that a variety of Potato which might gain the prize would necessarily be absolutely disease-proof for all time; but such a variety, after having been found to resist disease for three years, in twenty different localities each year, ought to be made widely known as the one which should be most generally cultivated. The point is this: either some one or more of the essayists to whom I have referred were right, and their statements were facts, or they were all wrong. In either case the judges thought that the society should sift the matter to the bottom, alike in the interests of the essayists, of Potato-growers, and of the public at large. This is exactly what the council have undertaken to do, if the possessors of these varieties of the Potato have sufficient faith in them to enter them for a fair and extensive competition. The scientific aspect of the Potato disease also received the careful attention of the judges of the essays; and, in their report to the council, they expressed their regret that no essayist appeared to be acquainted with the most recent discoveries in that field of inquiry. They, therefore, recommended the council to grant a sum of money for the purpose of inducing a competent mycologist to undertake a special investigation into the life-history of the Potato-fungus. The council have adopted this course also; and it is most gratifying to be able to announce that Professor de Bary, of Strasburg, the highest living authority on the fungi of our farm crops, and especially on the Potato-fungus, has undertaken this important investigation. I have thought it desirable to ask you to give publicity to this statement, not only with the view of making the action of the council of the Royal Agricultural Society more widely known; but, also, for the purpose of showing that Lord Cathcart's generous offer, although not productive of precisely the result which his lordship hoped, has already led to one investigation of national importance, towards the expenses of which he has devoted the money which he had destined for a prize essay, and which would have been most gladly accorded by the judges to any essay which exhibited a satisfactory solution of the question. It is perhaps remarkable that none of the essays sent in displayed much botanical acquaintance with either the root or its malady. H. M. JENKINS.

12, Hanover Square, W., Feb. 11, 1874.

NOTES OF THE WEEK.

— We are glad to see that Solomon's Seal (*Polygonatum multiflorum*) is now offered for sale among the forced flowers in Covent Garden. Among native plants there is none more graceful or interesting than this, and none more easily grown.

— We have received from Messrs. Hooper & Co., of Covent Garden, some tubers of the new American Potato called Snowflake. It is a white-skinned, flattish, shallow-eyed Potato very solid, and finely formed, and looks as if it would prove a welcome addition to our stock of garden Potatoes.

— MESSRS. POWELL, of Bayswater, write to the papers suggesting that a great improvement would result if the roadway of Portland Place were lined with trees or belts of shrubbery. There are other London thoroughfares to which the same advice applies, and even some of those planted are, like Westbourne Terrace, so wretchedly done that they require re-planting.

— AMONG the more remarkable Orchids now in flower in Mr. Wrigley's valuable collection at Bridge Hall, Bury, Lancashire, are *Calanthe nivalis*, three kinds of Lady's Slipper, many varieties of *Cattleya Trianae*, *Ceologyne cristata*, seven kinds of *Dendrobium*, *Epidendrum macrochilum*, various plants of *Lycaste Skinneri* with 256 spikes, *Lælia anceps*, *Miltonia cuneata*, nine kinds of *Odontoglossums*, and *Oncidium cheiroporum* and *Cavendishii*.

— ON Wednesday evening last Mr. S. Hibberd lectured at the Society of Arts on a "New System of Cultivating the Potato; with a view to augment production and prevent disease." His plan mainly consists in placing large arched tiles under the sets, laid in ridges 4 feet apart, at a cost of over £66 an acre. The lecturer did not claim that the system was likely to be useful in well-drained and naturally warm soils. The plan may be worthy of some attention from the curious amateur, or Potato fancier, wishing to grow a few Potatoes in a wet and undrained garden.

— WE have received the first number of the English edition of the *Illustration Horticole*, which contains coloured plates of the following plants:—*Oncidium fuscum* (*Miltonia Warscewiczii*), *Ceroxylon andicola*, and *Camellia japonica*, var. *Don Pedro*. The pages of the new issue are of a much larger size than those of the French edition to which we have been so long accustomed, are neatly printed, and, in other respects, well brought up to the present requirements of Horticultural journalism, which has made such marked progress during the last two or three years.

— AT last the Duke of Bedford has determined to cover in Covent Garden market. An extraordinary general meeting of the Market Gardeners, Nurserymen, and Farmers' Association was lately held at the Bedford Head Hotel, Covent Garden, to take into consideration the model of the proposed covering. Several of the members were of opinion that the proposed erection was not high enough, and that the 4 feet left open on either side was very objectionable. The openings at the side and the low roof were stated to be for the convenience of those persons who occupy the upper rooms over the shops in the centre row. So far as we could judge from the model exhibited, the improvement contemplated will be slight indeed to what is required.

— MESSRS LAWES & GILBERT have published an exhaustive report of experiments on the growth of Barley for twenty years in succession on the same land. The main results are the same as those previously obtained by the same gentlemen in the case of Wheat; viz., that when the same crop is grown consecutively on the same ground for a series of years, mineral manures alone fail to enable the plant to obtain sufficient nitrogen and carbon to yield even a fair crop; that nitrogenous manures alone increase it very considerably; but that the largest crops are obtained when nitrogen and mineral manures are applied together. In the case of Barley, these combined manures gave, for twenty years in succession on the same land, rather more of both Corn and straw than farm-yard manure did, and considerably more than the average Barley crop of the country grown under a system of rotation of crops.

— WE are requested to state that the trials of flowers to be undertaken at Chiswick this season are the following:—New Pelargoniums, for bedding purposes; Pelargoniums of the pink and rose-coloured sections, as pot plants; Fuchsias, as pot plants, grown to larger size than heretofore; Pentstemons, of which some very fine sorts bloomed late last year; and flowering Begonias of the boliviensis strain, now becoming so numerous. A collection of bedding Violas and Pansies is also being got together. Those who possess novelties which they desire to have tested, as well as those who are willing to render aid in making up the collections of these flowers, are invited to send their plants to Mr. Barron, the gardener-in-chief at Chiswick, as soon as they conveniently can. It may be mentioned, as an inducement to raisers of novelties to send their own productions

direct to Chiswick, that it has recently been decided, on the recommendation of the Board of Directors, to issue certificate cards in the case of all subjects certificated at the gardens, and which will, of necessity, be made out in the name of the donors. This has not hitherto been done, as the announcement has been reserved for the report, but, from the frequent delays which occur in the issue of the latter, it has been thought desirable to issue the certificates immediately after each of the Chiswick meetings.

— SOME fifty-nine lots of the pale blue Vanda (*V. cærulea*) were sold at Stevens' the other day. They realised from 10s. to 60s. per lot, each consisting of one plant. This valuable winter-flowering species is now scarce in its native habitats.

— THE anniversary festival of the Gardeners' Royal Benevolent Institution is to take place, this year, on Thursday, the 2nd of July; that is, the day after the great Rose show at South Kensington, and, we are informed, that many who will show Roses on that occasion have promised to send their plants from the Exhibition to the London Tavern, to assist in decorating the rooms. We, may, therefore, expect a grand floral display.

— IT is expected that the new Alexandra Palace will be ready for opening in June next. Great progress has been already made in the work of restoration, which is being pushed on vigorously. In addition to many improvements in its interior arrangements, as compared with those of its predecessor, the new structure will be furnished on the outside with four lofty contiguous water-towers, which will supply ample means of extinguishing any possible future conflagration.

— M. ALEGATIERE, the well-known Pelargonium-grower, has issued his catalogue of novelties for 1874, among which we notice the following double-flowered zonals, raised by M. Jean Sisley, viz.:—*Georges Sand*; flowers, large, white, if kept indoors, and assuming a slight rosy flesh-colour when exposed to the sun. *François Pertusati*; flowers, large, yellow, margined with white. *Carl Vogt*; flowers of medium size, of an orange-salmon colour, quite a new shade. All the foregoing are very free-flowering varieties.

— THE distinguished American statesman, whom Dickens so graphically describes as forwarding a pamphlet of his high eloquence to Queen Victoria, has been quite outdone by the Cranberry Growers' Association of New Jersey. The *New York Tribune* states that this society has immortalised itself by sending to that Royal lady two whole packages of Cranberries, and also divers recipes for the preparation of the same after the American methods.

— A SPECIAL general meeting of the Linnean Society is to be held on Thursday, March 5, at 8 p.m., "to consider alterations in the bye-laws of the society;" when it is expected a full explanation will be given of the reasons which induced the council to make the alterations recently adopted by the society, which met with so much opposition. It is understood that Mr. Bentham, who has occupied the chair of the Linnean Society for the past eleven years, will not offer himself for re-election. The custom of the society requires that the next president shall be a Zoologist, but students of both branches of Biology will be glad to learn that Professor Allman has allowed himself to be nominated. Few naturalists would bring to the office a wider, and none a more sympathetic knowledge.

— ACCORDING to Mr. Moule, chalk, mixed with anthracite for warmth, and mixed with lignite for lighting purposes, is to deposite coal and its relative gas altogether, and the public is to save at least 50 per cent. by the change. The extraction of the carbonic acid from the chalk, and its immediate application to kitchen and other fires, and to furnaces of every description, can be, Mr. Moule asserts, shown not only to be no impossibility, but to be perfectly feasible, requiring very little alteration in the present arrangement of grates and furnaces. When thus extracted and applied to anthracite, it produces a strong flame and heat, and at so slow a rate of combustion that a good fire was maintained for twenty-nine hours, in the furnace which heats Mr. Moule's church, with only half a hundred-weight of anthracite and an equal quantity of chalk mixed with it during that time. Through the aid of this remarkable property of chalk, the lignite known as shale may be used for the production of an illuminating gas to an extent which will appear incredible. Even the coarsest clay of this singular formation is full of gas; and Mr. Moule's experiments, though imperfect, satisfy him that one ton of this substance, with which Dorset and Norfolk abound, together with a due proportion of chalk, will yield as large an amount of gas as eight tons of ordinary coal. From these experiments, Mr. Moule argues that London might be warmed and lighted at a 50 per cent. cheaper rate than it now is; that the smoke, dust, and ashes nuisance might be abolished; and every good-sized country house and every village might be lighted with gas, while the kitchen-fire, with some slight alteration in the grate, might supply the house with light. Finally, lignite and anthracite beds would become valuable property, and chalk would be exported as coal is now. The prospect seems almost too good to be true.

THE FLOWER GARDEN.

SELECT HERONS' BILLS (ERODIUM).

ERODIUM MACRADENUM.—A valuable and pretty Pyrenean species, with leaves 4 to 6 inches long, twice divided, having a tendency to become recurved, which gives the plant a graceful appearance. The flowers are produced on stalks, 6 to 10 inches high, each bearing from four to eight flowers, the ground colour of which is a sort of French-white, delicately tinged with purple, and veined with purplish-rose; the lower petals are larger than the others; the two upper ones have each a dark-coloured spot, which at once distinguishes this species from the other *Erodiums*. The best position for this plant is in a crevice, tightly placed between two rocks, exposed to the hottest sun, where the roots can penetrate into dry sandy or stony soil to the depth of at least a yard. When grown in this way, this *Erodium* is an extremely pretty object, the leaves, by the dryness of the situation, are kept in a dwarf state, nestling to the rock, and the flowers are produced in great abundance during the summer months.

When grown in pots, I find it best to place the plant between two stones—either limestone or sand-stone will do; the crown of the plant should be raised one inch, at least, above the rim of the pot, which prevents it from damping off at the "neck" in winter. The plant has somewhat of an aromatic fragrance.

E. PETRÆUM.—Another interesting and useful kind, dwarfer, and having larger flowers than the preceding species. Leaves, 2 to 4 inches high, much divided, soft and velvety to the touch; flowers, purplish-rose, from three to five on each of the stalks, which are 4 to 6 inches high. The leaves and flower-stalks are densely clothed with minute hairs. It thrives best when planted in deep sandy or gravelly soil, in warm positions, amongst the dwarfer kinds of Alpine plants. The accompanying illustration is an excellent portrait of this plant.

E. MANESCAVI.—A strong and vigorous herbaceous plant, and by far the handsomest and showiest species of *Erodium* I am acquainted with. It grows from 1 to 1½ feet high, and throws up strong flower-stalks, which rise above the foliage, each bearing from seven to fifteen showy purplish flowers from 1 to 1½ inches across. Leaves, pinnate; leaflets, deeply toothed, opposite, and of a lively and pleasing green. The plant is not at all fastidious as to soil or situation. I have seen it growing in very stiff soil, almost clay, though in such positions it is liable to damp off in the winter months. The best position for its successful cultivation is in dry hard soil, fully exposed to the sun. If the soil be too rich, the plant produces its leaves in such abundance that the flowers are hidden by them. It is a very fine plant for pot culture. Propagated by seed, or by carefully cutting up the crowns in early spring.

E. HYMENODES.—This is a rather coarse-growing kind when grown in the ordinary border, and scarcely worthy of being cultivated excepting in the semi-wild garden on a dry

bank, or it might be tried on an old wall. It produces its flowers during the summer and autumn months; they are pale pink. In foliage and habit it is somewhat similar to *Geranium sanguineum*.

E. REICHARDI.—A miniature member of the vegetable kingdom, growing only about 2 to 3 inches high when in flower; the leaves are small, heart-shaped, and lie close upon the ground, forming little tufts, from which arise slender stalks, each bearing a solitary white flower, marked with delicate pink veins. It often continues in flower for many weeks. This *Erodium* should be grown amongst the dwarfiest and choicest Alpines, such as the *Androsaces*, *Gentians*, &c., in gritty peat mixed with a small portion of loam. R. P.

York.

[To the foregoing may be added:—*E. caruifolium*, a plant from 6 to 10 inches high, with gracefully-cut pinnate leaves, the underside of which is covered with soft, white, downy hairs; flowers, red, about ½ inch in diameter, and borne in umbels of nine or ten blossoms. *E. alpinum*, which resembles *E. Manescavi*, but is much dwarfer, growing 6 to 8 inches high, and flowering continuously from spring to autumn: flowers of a handsome

violet-red or carmine, about an inch across, in umbels of six to ten blossoms each. *E. romanum*, allied to the British *E. cicutarium*, but with larger flowers; grows 6 to 9 inches high; flowers, purplish, appearing in spring and early summer. *E. trichomanefolium*, a very pretty dwarf kind, 4 to 6 inches high, with leaves so deeply cut as to resemble a Fern; flowers, flesh-coloured, marked with darker veins. All the preceding, with the exception of *E. Manescavi* and *E. hymenodes*, are admirably suited for rock-work or borders, in light sandy or calcareous loam. *E. Manescavi* should, perhaps, be confined to the border, as it is somewhat too tall and space-filling a subject for the rock-work; while *E. hymenodes*, as observed above, finds its most fitting place

Erodium petraeum.

in rough semi-wild parts of the garden or pleasure-ground.—Ed.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Phloxes.—The best of those grown at Chiswick last year were Carl Klein (F. & A. Smith), rosy-lilac with crimson eye; Dame Blanche (Henderson), white with pale rosy eye, pips large; Lady Hulse (Parker), bright rosy-purple; Le Léon (Downie & Co.), lilac with crimson around the eye, the later flowers striped and tipped with crimson; Mons W. Bull (ditto), lilac, with white blotches at the base of each segment forming a radiating white eye; Roi des Roses (ditto), bright rosy-crimson with carmine eye; and Mons. Taillard (Veitch), bright rosy-salmon with dark eye, brighter than Lothair.

Abronia fragrans.—This fine species, though less amenable to treatment than *A. umbellata* and *A. arenaria*, is, unquestionably, the most remarkable of the genus. It differs from the species just named, in being usually more or less erect in habit, forming rather large branching tufts, from 12 to 16 inches in height, and covering, when the root is strong, 2 or 3 square feet of ground, the stems being decumbent at the base. The flowers are produced in umbels at the extremity of each lateral, and when fully expanded are pure white, diffusing a vanilla-like fragrance for some distance. During the earlier part of the day, the limb of the corolla is folded inwards, exhibiting only the greenish-white tint of the exterior, but about 4 o'clock the expansion commences, and speedily results in a transformation which is almost startling. The flowers, which are larger than in *A. umbellata*, are produced till very late in the season. It succeeds best in friable or light soils. The plant has been introduced by Mr. Wm. Thompson, of Ipswich, who this year offers seed of it.

THE INDOOR GARDEN.

VARIEGATED ORCHIDS.

(ANÆTOCHILUS AND GOODYERAS.)

WE have many Orchids with variegated foliage; and, as they are not less beautiful in their way than those whose only attraction is their flowers, they are well worthy of consideration. Several of our British species, as *Orchis mascula*, *O. pyramidalis*, and others, have bright glossy leaves, profusely blotched with purple, and, when closely examined, are found to be extremely beautiful. Many tropical Lady-Slippers, as *Cypripedium venustum*, *C. concolor*, *C. barbatum*, and *C. Hookeriæ*, are well-known examples of leaf-beauty, the foliage being blotched or barred irregularly with dark green and light green ground colour. We have recently seen some variegated sports on *Dendrobium nobile*, *D. japonicum*, and a pair of variegated plants of *Odontoglossum crispum* were sold at Stevens's Rooms some time ago. These were very prettily striped with creamy-white, and served to create a variety among the ordinary green-leaved kinds. There are also other Orchids more or less variegated; but the best of all are the *Anætochilus* and *Goodyeras*, and to these we shall now direct attention.

ANÆTOCHILUS ARGYRONEUROS.—A very pretty little plant, especially when examined closely with a lens or magnifying-glass, which is the best way of looking at these brilliantly tinted gems. It grows about 3 inches in height, having dark green leaves, suffused here and there with a lighter tint, the whole surface of the leaf being most beautifully reticulated, or netted, with bright silvery veins. This plant grows very freely. A native of Java.

A. DOMINII.—One of the best, and one which possesses additional interest, inasmuch as it is a garden hybrid, raised by Mr. Dominy, between *A. xanthophyllus* and the well-known winter-blooming *Goodyera discolor*. Its foliage, which is robust, is of a deep velvety-green, marked with silvery lines or veins, the central streak being of a pale copper colour. This singular hybrid has a good constitution; but is, as yet, rather rare.

A. INTERMEDIUS.—This is an extremely pretty species, and one which possesses a better constitution than many others. It grows freely, and has leaves of a rich olive-green, marked with golden veins, the whole plant being 2 or 3 inches in height.

A. JAVANICUS.—This appears to be rather uncommon in collections, but is of free habit and well worth growing. The ground colour of its foliage is of a dark olive tint blotched distinctly with light green. I have found this plant rather liable to damp off if grown under a shade or in a close case. It does well, however, in an ordinary stove temperature, if potted in light fibrous material, and carefully watered. When the plant is fully exposed it may be syringed freely, always taking care to use tepid water only.

A. LOWII.—This is the strongest of the whole genus, and is, at the same time, one of the best for general cultivation. The whole plant varies from 5 to 8 inches in height, each leaf being 4 or 5 inches in length, and about one-third less in width. The foliage is of a deep velvety-green, the youngest leaves being shaded with warm yellowish-brown, and the whole surface covered with longitudinal and transverse markings of a bright copper colour or golden hue. Of this plant there is a variety with lighter-tinged foliage and brighter golden markings than this species. The finest plants of it I ever saw were grown by Mr. Diamant, gardener to Lieut.-Colonel Holdsworth, Green Royd, Halifax. These were growing in a case similar to one which I shall hereafter describe, and were the picture of health and beauty; some of the plants were 8 inches high and as much through, and were grown in small pots plunged in living *Sphagnum*. When well managed this species is one of the finest of all dwarf-growing foliage plants. It is a native of Borneo, whence it was introduced by Mr. Hugh Low.

A. (MACODES) PETOLA.—This is smaller than the last-named species, but grows very freely under the same cultural conditions, and is equally easy to multiply by means of cuttings made of the rhizome. Its leaves are from 2 to 3 inches long, and of a light velvety-green, profusely banded and veined with gold. This beautiful species should be one of the first

selected by beginners, as it seldom disappoints the cultivator, and is invariably admired for its rich velvety texture and golden illuminations.

A. SETACEUS.—An old inmate of our gardens, and an elegant plant when well grown. Its leaves are about 2 inches long, and of a bright velvety-green, charmingly netted with gold. Of this very variable plant three or four tolerably distinct forms are in cultivation, each differing from the other in the shape of the leaf and in the breadth and density of its markings.

A. VEITCHII.—This is nearly as robust in habit as *A. Lowii* which it somewhat resembles. Its leaves are about 3 inches in length, of a beautiful pale green colour, veined and barred with a still lighter tint. It is a kind which should be in every collection on account of its robust habit, but it nevertheless seems to be somewhat uncommon in private gardens.

A. XANTHOPHYLLUS.—This, though an old species, is one of the best in cultivation. It grows, freely treated, like its congener, and, when well grown, is a very beautiful foliage-plant. Its leaves are about two inches in length, of a rich green colour, and soft velvet-like texture. Each leaf is striped down the centre with broad masses of orange, and the whole of the leaf is covered with an intricate golden network of the greatest brilliancy.

GOODYERA DISCOLOR.—This well-known plant is not only valued for the beauty of its foliage, but is worth growing for its spikes of milk-white flowers, which are produced so profusely on strong specimens during the winter months. All the *Goodyeras* grow well, treated like *Anætochilus*, but they do not, as a rule, require so much heat, and can be grown in any ordinary plant stove. The leaves of *G. discolor*, which is a Brazilian species, are of a dark green above and bright reddish-purple beneath.

G. DAWSONIANA.—This is a much larger-growing species than the last, each leaf being about 3 inches in length, of a deep and rich velvet-like green, traversed with copper-coloured lines. This plant flowers freely, and bears spikes of white flowers, a foot in height, exactly like the last. It comes from the Malayan Archipelago.

There are several other species of *Goodyera* in cultivation, but these are two of the best for general culture.

The compost best suited for the growth of both *Anætochilus* and *Goodyeras*, is one composed of fresh fibrous peat, chopped living *Sphagnum* Moss, and sufficient coarse well-washed sand to keep the whole open and porous. It is highly essential that the drainage be perfect, as nothing tends to prevent these plants from developing themselves as stagnant moisture, especially at the root. When making their growth during the summer months the free use of tepid water is beneficial, and they must never be allowed to get thoroughly dry. *Anætochilus* are not difficult of propagation, as every joint of the rhizome is furnished with a latent bud, which seldom fails to push into growth when the top is removed, and the top itself may be treated as a cutting, or, if possible, remove it with a few roots. These plants are generally grown in flat pans, and covered either with an inverted bell-glass or a glass-case. The finest plants of *A. Lowii*, *A. setaceus*, *A. Veitchii*, *A. intermedia*, and some others, were growing in a case about 4 feet long and 3 feet wide. This case had a glass top, the sides and ends being covered with perforated sheets of zinc. It was placed on the slate bench of a warm plant-stove, and effectually protected the plants from cold draughts, while, at the same time, it allowed a free circulation of warm air around the plants. This is especially necessary to the vigorous growth of these delicate plants, for they are most impatient of stagnant moisture either at the root or overhead, and, if covered with bell-glasses, it is essential to wipe the latter quite dry, every morning, or the condensed moisture often induces the leaves to spot and decay. A plant-case, similar to the one above described, is very useful, not only for these plants, but for many other stove foliage plants equally tender, or for propagating purposes, since nothing is more common, than for delicate seedlings to damp off in the close cases generally employed.

The foregoing species are those best worth growing for their foliage, and will add interest to the most select collection of Epiphytes.

F. W. B.

A FUCHSIA CHANDELIER.

THE accompanying illustration shows one of the many ways in which Fuchsias may be trained so as to suit particular purposes. It represents a Fuchsia Corallina hanging down, chandelier-fashion, from the roof of the conservatory at Chiswick House. A branch was trained downwards from a plant that was planted, about seven years ago, against one of the supports of the dome of the conservatory. This shoot was stopped, three or four buds broke, and when these had grown a year or so they were trained somewhat in the shape of an umbrella. The branch in question has grown to its present size in three years, and is now a really pretty and interesting object, flowering as freely as the branches do that are growing more naturally. Its growth, as may be seen by the annexed

A Fuchsia Chandelier.

sketch, is at right angles with its support, and it often surprises me that the sap should so freely descend, as it does, under such disadvantageous circumstances. C. EDMONDS.

HARDY WINTER CONSERVATORY PLANTS.

DEUTZIA GRACILIS.—I consider this the most beautiful and graceful of all shrubs for the decoration of the conservatory in winter, and all will agree with me that little trouble is required to induce it to produce its white flowers in profusion at that season. In many places, where this Deutzia has finished flowering, it is stowed away behind stages, or in any out-of-the-way place, until a suitable time has arrived to turn it out of the pot, in which it has been grown in, and to plant it in some out-of-the-way border, to prolong its existence until required for forcing again. The following mode of culture I have, however, found to be the best:—Last spring we had two dozen of two-year-old plants in 7-inch pots, which, when they had finished flowering, were removed to a Vinery with a temperature of 60°, where they finished their growth; afterwards they were removed to a cool frame, until they had begun to grow again, when they were set on pieces of slate behind a north wall and there left to the mercy of the weather. On the first of the following September, they were shaken out of their pots, root pruned, and potted in the same pots they previously occupied, and returned to the frame, where they remained dry until the 5th of November; after which, eight of them were put into a Cucumber-house, and by Christmas they were in full flower and in the conservatory; another eight

succeeded them four weeks afterwards; and the third eight is still in the frame, with no appearance of starting. No water is given to them until the buds begin to swell, and even then it is only applied in limited quantities, until both top and root are fairly in action.

THE HAWTHORN (*Cratægus crenulata*).—This should be largely cultivated as a winter or early spring plant for the conservatory. The white variety seems more willing to flower than the red or pink kinds, but all are worthy of attention, as they produce a grand effect among other plants during the dull season of the year. On the 1st of September we lifted six plants from a thicket, which had been planted two or three years ago, potted them in 10-inch pots, using a stiff clayey loam, with a good mixture of sand in it, and placed them behind a north wall, where they remained with no further attention until the 5th of November, when they were started in a Vinery, and they are now (especially the white sort) in a perfect sheet of blossom.

THE LABURNUM (*Cytisus Laburnum*).—Although the Laburnum blooms early out of doors, a few plants of it a couple of months earlier in the conservatory are not objectionable. We grow two sorts of *Cytisus* here, viz., the purple and yellow. The yellow sort is on its own roots, and, although not yet in flower, it promises to be a mass of golden tresses. Both are grown in 10-inch pots, and, being rather tall, they do well for background plants. In summer they are set out of doors, watered occasionally, and allowed to grow unchecked. They are dried off a month before those in the shrubbery begin to throw off their leaves in order to give them a long rest prior to forcing. The soil we use for them is a light sandy loam, with a good mixture of peat in it, and when in growth they can scarcely be over-watered, and they are greatly benefited, too, by giving them an occasional application of liquid-manure. The points of the young shoots may be pinched off, but as few as possible of the shoots themselves should be entirely cut off, as these produce the following year's flowers. The purple *Cytisus* does best whip-grafted on the yellow stock, as the shoots grow stronger, and the buds become more plump when thus treated. The treatment suitable for the yellow kind answers for the purple, only the latter ripens its wood better and goes off to rest sooner than the yellow-flowered sort.

THE PERSIAN LILAC.—This, as usually managed, seldom flowers well when forced. It is a common plan to lift plants of it from a back shrubbery, cram them into a large-sized pot, and at once place them in a temperature of 60° or 65°. Even under such management I have seen flowers produced in November or December, but so miserable have they been as to be scarcely worthy of notice, and the shoots produced under such circumstances resembled knitting-pins more than healthy wood. We select stubby well-ripened plants, and lift them in November, root-pruning them to suit the pots into which they are to be put, leaving room for an inch or more of good sandy loam, which must be pressed in rather firmly with a blunt-pointed stick. This done, they are placed in an airy open situation, and are allowed to grow at will during the spring and summer, never permitting them to become dry, and encouraging them, now and then, with a little manure-water. Towards the end of August they are put under cover, and, when at rest, another shift, with a handful of half-inch bones placed over the crocks, is given them. About the 1st of October forcing begins, rather slowly at first, the plants being kept as near the glass as possible to prevent them from becoming spindly. Under this treatment excellent heads of bloom are obtained by the end of December.

LILY OF THE VALLEY.—The Lily of the Valley may be had in flower, in pots, during four months of the year, viz., from the 1st of November until the end of February. I have seen it stand in a temperature of 60° for two months without the least sign of starting. For pot culture, we do not plant out the roots at all, but grow them always in pots, shaking them out and potting afresh before starting them, which is done in a dung-frame, from which light is wholly excluded until the buds have burst, after which the plants are gradually introduced to light. Care is taken not to let them become blanched in the frame, as, in that case, they start too fast. Thus managed, fine potfuls of this favourite little Lily may be obtained.

Wotton Gardens, Aylesbury.

JAMES MORRISON,

A Cool Fern Grotto.—In the Botanic Gardens at Glasgow, there is a small Fern grotto sunk a few feet into the ground and covered with green-painted glass. The walls are steep, and in the form of rugged banks, or rock-work, entirely covered with cryptogamic vegetation, which thrives apace. The crevices between the stones being filled with turfy peat, all is kept moist, and frost is excluded by covering the roof, when necessary, with mats. Thus situated, specimens of *Todea superba* looked remarkably healthy, some of their fronds being 2 feet in length, and proportionally wide; *T. pellucida* was, also, equally vigorous. Some time since, Mr. Bullen, the curator, received a plant of *Todea Wilkesiana* (of which an illustration is given at p. 181, Vol. III. of *THE GARDEN*) from Messrs. Veitch, of Chelsea; when it arrived, he placed it in a Fernery in which intermediate temperature was maintained, but it never attempted to grow. By way of experiment it was transferred to this grotto a few months ago, and, since then, it has formed a well-developed frond, and others promise to succeed it. *Hymenophyllum Tunbridgense*, *Wilsoni*, and others, seem quite at home in the peat here, creeping over the stones as if in their native habitats; and there are large masses of the Killarney Fern growing in pouches on the rock-work, and in clumps at its base. One of the prettiest objects, however, in this Fernery, is *Lycopodium clavatum*; this grows luxuriantly, creeping over the surface of both rock and turf, and forming a pleasing contrast with its truly interesting associates. This *Lycopod*, which is sold in Covent Garden Market under the name of "Stag's-horn" Fern, is a suitable plant for a cool moist rock-work. On rocks bordering the Caledonian canal, and on other mountainous and rocky portions of Ross and Inverness, I have seen this *Lycopod* carpeting the ground, and creeping hither and thither in all directions between the stalks of Heather and Cranberries, as well as over the ledges of the rock. It, however, likes moist land best. If the plants become dry overhead during the daytime, they are sure to be bathed with dew at night, both naturally and by evaporation arising from the dampness of the ground.—W. F.

A Remarkable Date Palm.—In the *Revue Horticole*, M. Nardy describes a singular variety of Date Palm at present growing in the garden of M. Denis, at Hyères (Var). It is one of twenty young Date Palms which were planted in two parallel lines in 1845, and which now form a shady summer retreat. The young plants grew with various degrees of vigour, and now present a great diversity in the length of their trunks, which vary from 8 to nearly 20 feet. The subject under notice, however, differs from all the others in the remarkable arrangement of its leaves, which are gracefully disposed in a spiral manner round the stem, like the leaves of a *Pandanus*, in consequence of which M. Nardy has given it the name of *Phoenix dactylifera spiralis*. This tree has borne an abundance of very large fruit, from which seedlings have been raised, and M. Nardy is not without hope that some of these will reproduce the very interesting and pleasing peculiarity of their parent.

Forcing Lily of the Valley in Holland.—In order to grow strong clumps of Lily of the Valley, in January or February, dig up single crowns and tie them up in bundles of ten or twelve together; plant them in a soft loamy soil, well manured with cow dung, at a distance of 10 or 12 inches between the bundles. The position should be a shady one, and the plants should not be disturbed for three years, when they will be found to have formed good clumps. Plants, thus treated, are remarkably well adapted for forcing. For this purpose, plant them in pots of suitable size, covering the crowns with an inch or two of soil, and then plunge the pots, for a fortnight or so, in Cocoa-nut fibre. By that time they will be well-rooted. The pots may then be placed on the benches of a hot-house, or plunged in a hot-house in Cocoa-nut fibre, which should cover them to the depth of 5 or 6 inches. They should be left there until the plants appear above the surface of the fibre, when the pots should be taken out and put, for a few days, in a warm and shady place, after which they may be removed into a well-lighted house. This is the mode of treatment commonly practised in Holland, and, from experience, I can pronounce it a most satisfactory one.—C. J. L. VAN DER MEER, 2, Cheshunt Terrace, Tottenham.

Tree and Pyramidal Mignonette.—Although I find it easy to grow Mignonette in the form of pyramids and standards, yet few grow it successfully in either of these ways. If I wish to have standards, I sow in July or August in 32-sized pots, and as soon as the plants are large enough, they are thinned out to one plant in each pot. As growth progresses I train this plant in an upright manner until it reaches the desired height, say 3 feet. The side shoots must be removed from the stem, but in such a way as not to injure the foliage with which the stems should be furnished, and which, in my opinion, improves their appearance. The head may be trained upon umbrella-shaped wire, and the flowers must be nipped out until the desired size is attained, when the stopping should be discontinued, and, in four or five weeks, the plants will be ready either

for exhibition or house decoration according to the time of year. Pyramids are, however, my favourites, they bloom more profusely, and have spikes of a finer quality than standards, and they likewise last longer. These may be trained in a stiff and formal way on wires, but trained to sticks is much more natural, and looks best. I find about 2½ feet in height, and as much in diameter at base, to be better than having a greater height. In October, when they ought to have filled their pots with roots, I shift them into their flowering pots, as I know of no plant that dislikes disturbance at the root more than Mignonette. I have tried it in various soils, but I have come to the conclusion that three-parts stiff loam, such as that which a good Melon grower might choose, dry and well-decayed cow-dung, with a good sprinkling of soot mixed, suits it best. Chop all this up roughly, crock well, and pot moderately firm; place them in a cool house, from which frost is excluded, and attend to tying and similar work. Never allow the plants to become dry, and water alternately with liquid-manure and pure water.—D. GILLET, *Court Garden, Great Marlow.*

Orchid Culture in New Jersey.—We had here a very fine variety of *Lycaste Skinneri*, with two flowers on a stem, last autumn; also, about forty stems of *Cypripedium insigne* with two flowers on each; one plant had five stems with two flowers on each. I may add, however, that these plants were very showy, and that both the single flowers and pairs were extra large and fine. From a batch of plants covering a space of 12 feet by 4 feet, I cut nearly four hundred flowers during Christmas week of *Cypripedium Roezlii*. We have a plant which commenced to flower from two stems in the summer, the one stem had but four or five flowers, which were comparatively soon over, but the second stem has at the present time (January 27) the ninth flower expanded, and each flower lasts on the average three weeks. Thus you will see that the plant has already been in flower about six months, and there are other buds to open, which will probably make up a dozen on one stem; usually a second flower opens a day or two before the preceding one drops off, but, of course, there are only the two flowers open at once, and that only for a short time. I consider this species to be one of the finest of the *Cypripediums*, both on account of its beautiful rosy colour and peculiar twisted tails, as well as on account of its beautiful pale green recurved foliage. The leaves of one large plant here measure more than 2 feet in length, and 2 inches in breadth. *Cattleya Trianae*, I do not think, has been thoroughly appreciated in Europe, for I recollect some time ago complaints being made that it lasted but a few days in flower; even if that was true, however, it would be worth growing, but I have plants of it with flowers in full beauty, which were open on the 1st of the month, and which appear likely to last another week. It is thus clear that they are good for four weeks when subjected to the ordinary treatment of the *Cattleya*-house, and to the bright sunshine which we get in this country. Of course, care is taken to keep water from the flowers. Out of a dozen plants in blossom at once, no two were exactly alike in colour, but all were lovely. The gems among the varieties of *Trianae* were some pure white flowers with deep yellow throats; these were far superior to the best variety of *Warszewiczii delicata*, which was in flower at the same time. I consider the white *Trianae* to be the most lovely *Cattleya* I have seen, and can be only compared in purity with *Cælogyne cristata*.—JAMES TAPLIN, *South Amboy, U.S.A.*

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Asplenium fragrans.—I saw some nice specimens of this pretty little Fern a few days ago at the nurseries of Messrs. J. & R. Thyne, at Glasgow. Its fronds are from 9 to 15 in. long, and deliciously scented. Messrs. Thyne's foreman found it near the Falls of Niagara, in which neighbourhood it grows thickly. People living in the vicinity of the falls, I was told, often gather the fronds, and use them, when dried in the sun, for stuffing beds.—W. F.

The Crested Adiantum (*Adiantum cristatum*).—I have just seen a nice specimen of this rare and beautiful Maiden-hair Fern in Messrs. Rollisson's Nurseries, at Tooting, and think it one of the most interesting of the whole group. It has a sturdy habit of growth, something resembling a small plant of *A. villosum* in general appearance, but easily distinguished by the peculiar manner in which the sori or spore-cases are arranged on the margins of the pinnules, so that they are seen when looking on the upper surface of the fronds, as well as from below. It is one of the rarest species in cultivation, and deserves general cultivation.—B.

Darlingtonia californica.—I have a small plant of this, and wish to know how to be successful in treating it, as it does not grow much, and seems to have declined in health since I bought it. It is now in a plant-stove.—J. FRASER. [This plant is a native of California, where we have seen it growing amongst Grasses, Sedges, and Moss, in moist situations. You should gradually inure your plant to a cool and moist temperature, such as that of a frame or cool pit, protected from actual frost. It should be potted in a compost of fibrous peat and living Sphagnum, and, if plentifully supplied with water at the root, it ought to do well. It should never be rested or allowed to become quite dry. It is nearly, if not quite, hardy, and a plant in Messrs. Backhouse's Nursery, at York, has withstood one or two sharp winters planted out along with the Huntsman's Cap (*Sarracenia purpurea*) in their interesting bog-garden. It ought to grow luxuriantly in Devonshire and Cornwall, planted out in peat and living Sphagnum, in a marsh or artificial bog-garden.—Ed.]

THE ARBORETUM.

THE HARDIER KINDS OF VIBURNUM.

Deciduous Varieties.

1. THE LARGE-HEADED GUELDER ROSE (*Viburnum macrocephalum*).—This forms a large bush or low tree, covered all over with coarse, starry, scurfy hairs. It is a native of the north of China, and was introduced in 1844 by Mr. Fortune who speaks of it thus:—"This noble species is found in all the gardens of the rich in the north of China, and there is a tree of it growing in a garden on the Island of Chusan, at least 20 feet high, which, in the month of May every year, is covered with its snow-white blossoms." He also adds that when it is grafted on the wild form of the species, it blossoms on small plants in pots, and is then not unlike a white Hydrangea, by which name it is known among the Chinese. Its leaves are exactly ovate, very blunt, slightly toothed on the edges, quite flat, on short foot-stalks, and about 3 inches long; the flower-heads are terminal, and appear along with the young foliage in April and May. The flowers are pure white, and produced in large compound cymes, which, in the sterile-flowered or cultivated form, are as much as 8 inches in diameter, not, however, globular, like those of the Guelder Rose, but rather pyramidal, each flower being fully $1\frac{3}{8}$ inch in diameter, and lasting in perfection for a considerable time. The wild form of the species upon which the Chinese graft the beautiful garden variety, displays none of the grand and striking appearance of the sterile-flowered one, which is one of the very finest hardy deciduous shrubs that we possess at the present time.

2. THE PLAITED-LEAVED GUELDER ROSE (*V. plicatum*).—This fine hardy shrub grows from 4 to 10 feet in height, and has glabrous reddish-brown branches. It is found in the north of China and Japan, and was first introduced in 1844 by Mr. Fortune, who says that it is found cultivated in all the gardens of the rich, and forms a bush from 8 to 10 feet high, which, in May, is loaded with its globular heads of snow-white flowers, which are about the size of those of the common Guelder Rose. Dr. Siebold says it grows from 4 to 6 feet in the woods of Japan, and is seen cultivated in nearly every garden in Japan. Its leaves are broadly ovate, abruptly pointed, tapering to the base, coarsely serrated on the edges, crimped or plicate, and dark green above, veiny and tomentose beneath, and about 3 inches long. The flower-heads are terminal, and produced in great profusion on the lateral branchlets in April and May, just as the young leaves are unfolding, the flowers are in globular heads, snow-white at first, but just before they fade,

usually assume a purplish tint. In the wild state this kind has some of the flowers radiant and sterile, and others small and pentandrous, and is generally known under the name of *Viburnum tomentosum*. Its Japanese names are Sije, Adsai, and Satsuma-Temari, or Globe flower. This *Viburnum* is quite hardy and a most beautiful shrub when in flower in May.

3. THE COMMON GUELDER ROSE (*V. Opulus*).—This forms a large bush or low tree, from 10 to 15 feet high. It is a native of Britain and throughout Europe, in hedges and thickets, in damp and swampy places. Its leaves are broad, three-lobed, acuminate, unequally serrated, veiny, and quite glabrous in every part, with the petioles beset with glands towards the top, and several oblong leafy appendages lower down. The leaves

are bright green in summer, but in the autumn they assume a beautiful crimson hue. The flowers are white, and produced in pedunculate cymes with linear bractæas, and with several of the marginal flowers dilated, flat, radiant, and sterile. The berries are elliptical, bright red, and, when ripe, in September, very ornamental. Of this there are the following varieties:—

THE SNOWBALL TREE (*V. Opulus sterile*).—This only differs from the wild form in having nearly the whole of the flowers sterile, and collected into a compact, round, globular ball or head. It is sometimes named *V. Opulus roseum*, not from the colour, which is pure white, but from the shape of the head of flowers resembling a double Rose.

THE VARIEGATED-LEAVED GUELDER ROSE (*V. O. variegatum*).—This variety only differs from the species in having the leaves variegated white and yellow.

THE DWARF GUELDER ROSE (*V. O. nanum*).—This forms a singular dense little bush, rarely exceeding 1 foot in height, and which never produces any flowers. It originated in the nursery of Messrs. Lee, of Hammer-smith, and frequently bears the name of *V. pygmaeum*. The kinds known as *Viburnum edule*, *Oxycoccus*, and *molle* are only slight American forms of the common European *Viburnum Opulus*.

4. THE MAPLE-LEAVED GUELDER ROSE (*V. acerifolium*).—This grows from 4 to 6 feet high, and has

pilose branchlets. It is a native of North America, from New England to Canada, and of Newfoundland, in rocky mountainous situations. It was introduced in 1736. Its leaves are ovate, cordate, usually three-lobed, acuminate, sharply and loosely serrated on the edges, downy beneath; petioles, glandless, when young, stipulaceous at the base, and rather tomentose. The flowers are white, in terminal pedunculate corymbs, which are not radiant, and are produced in May and June. The berries are oval, compressed, and black when ripe in September.

5. THE WAYFARING TREE (*V. Lantana*).—This small tree or large bush grows from 6 to 15 feet high, and has copious,

Large Guelder Rose (*Viburnum macrocephalum*).

opposite, round, pliant, mealy branches. It is a native throughout Europe, and is common in Britain, in woods and hedges, especially on chalky or limestone soil. Its leaves are rather large, cordate, rounded, finely serrated on the edges, veiny, and thickly clothed beneath, but more sparingly so on the upper side, with starry mealy pubescens, like that on the branches and petioles, and in the autumn, just before they fall off, turn to a dark red colour. The flowers are white, and produced in broad, flat, crowded, pedunculate cymes in May and June; bracteas, small, numerous, and acute; berries, compressed, and, in the young state, red on the outside, and yellow on the inner one, but when ripe, black, with a little mealy astringent pulp; seeds, large, flat, and furrowed. Of this kind there is a variety which has the leaves variegated with white and yellow.

6. THE AMERICAN WAYFARING TREE (*V. Lantanoides*).—This forms a robust-growing bush from 6 to 10 feet high, with the branches thickly covered with a powdery tomentum. It is a native of North America, from Canada to Carolina, particularly in the forests about Quebec and Lake Huron, where it is called the Hobble bush; it was introduced in 1820. Its leaves are large, broad, roundish-cordate, abruptly pointed, unequally serrated on the edges, and clothed with a powdery tomentum on the nerves and petioles. The flowers are white, and produced in nearly sessile, large, terminal corymbs, with the outer flowers abortive and radiant; the fruit is oval, and, when young, red, but when ripe in September, quite black. Its synonyms are *Viburnum Lantana grandifolia*, *V. L. canadense*, and *V. L. latifolium*.

7. THE INDIAN WAYFARING TREE (*V. cotinifolium*).—This robust shrub, or low tree, grows from 10 to 20 feet in height, and has grey branches, thickly clothed with stellate tomentum. It is a native of the Valley of Nepal, Kamaon, and the Himalaya Mountains, at an elevation of from 5,000 to 7,000 feet, and was introduced in 1832. Its leaves are roundish-ovate, cordate, entire, or slightly dentately serrated on the edges, densely clothed with stellate down on both surfaces when young, but when fully matured nearly glabrous above, grey beneath, and 4 inches long, and $2\frac{1}{2}$ broad. The flowers are white, tinged with pink when young, obconical in shape, and rather large, they are produced in rather large terminal, nearly sessile, compound, spreading, woolly corymbs in April and May; the fruit is oval, bright scarlet, and said to be eaten by the people in Nepal. This kind is rather tender, and requires protection in winter, or to be planted against a south wall, where it makes a fine display, when in flower, in May. Its synonyms are *Viburnum stellatum*, *Mullaha polycarpum*, and *nervosum*; the Nepalese name for it is Phee-laroo, or the Eagle's bush.

8. THE DAHURIAN VIBURNUM (*V. Dahuricum*).—This forms a somewhat spreading bush from 6 to 8 feet high, and has grey downy branches. It is a native of the Dahurian mountains, and was introduced in 1785. Its leaves are ovate, somewhat cordate at the base, crenately serrated on the edges, not very large and beset with stellate down on both surfaces. The flowers, are yellowish-white, tubular, somewhat funnel-shaped, bluntly five-toothed, and produced in forked, terminal, few-flowered corymbs in July and August. The fruit is oval-oblong, five-seeded, at first red, but finally, when ripe, in September, black and rather sweet-tasted.

9. THE DILATED VIBURNUM (*V. dilatatum*).—This small hardy shrub grows from 3 to 4 feet high, with greyish branches and shoots, when young, furnished with a few rough hairs. It is a native of China, at Teitung, near Ning-po, and was introduced in 1846, by Mr. Fortune. Its leaves are ovate or obovate, pointed, regularly and coarsely toothed on the edges, plaited and bright green above, pale beneath, and with a few rough hairs on both surfaces. The flowers are white, and produced in May and June, in small, spreading cymes, destitute of any tenderness to become radiant; fruit, small, and nearly black. It is one of the least ornamental of all the species, as the flower-heads are small and not showy. Its synonym is *V. erosum*.

10. THE TOOTHED-LEAVED VIBURNUM (*V. dentatum*).—This forms a rather slender shrub, from 4 to 6 feet high, with smooth shoots. It is a native of North America, from New York to Carolina, in mountainous woods and was introduced in 1763. The leaves are ovate, or nearly orbicular plaited, coarsely and dentately serrated, glabrous on both surfaces, with

the nerves thick and feathered. The flowers are white and produced in June and July, in pedunculate corymbs or cymes. The fruit is small, nearly globose, dark blue and crowned with the calyx. There is a nice variegated-leaved variety. Its synonyms are *Viburnum dentatum*, *lucidum*, *montanum*, and *dentatum glabellum*. In America this shrub is known by the name of Arrow-wood.

11. THE DOWNY VIBURNUM (*V. pubescens*).—This assumes the form of a small slender shrub, seldom exceeding 3 feet in height, with downy shoots, particularly when young. It is a native of North America, in the lower parts of Virginia and Carolina, and also of Canada about Lake Winnipeg. The leaves are ovate, acuminate, on short petioles, slightly serrately toothed, villose beneath, with the nerves feathered and prominent. The flowers are white, and produced in June and July, in rather small pedunculate corymbs. Fruit, small, ovate, and dark blue. Its synonyms are *V. villosum*, *V. dentatum pubescens*, *V. Rafinesquianum*, *V. longifolium*, and *V. acuminatum*.

12. THE PLIANT-BRANCHED VIBURNUM (*V. Lentago*).—This forms a large bush or low tree from 10 to 12 feet high; it has a spreading head, and when trained to a single stem, makes a fine subject for planting singly on the lawn. It is a native of North America, from New England to Carolina, among hedges and on the borders of woods; it is also found throughout Canada, and was introduced in 1761. The leaves are broadly-ovate, pointed, sharply serrated on the edges, quite glabrous, and of a shining deep green on the upper surface in summer, but in the autumn, just before they fall, change either to a purple, red, or yellow colour. The flowers are white, and produced freely in terminal sessile corymbs in July. The berries are oval, black when ripe, in September, and produced in great abundance.

13. THE PLUM-LEAVED VIBURNUM (*V. prunifolium*).—This kind forms a large spreading bush, from 6 to 8 feet high, and has rather slender branches. It is a native of North America, from New England to Carolina, in hedges, also about Lake Huron, in Canada, and was introduced in 1731. Its leaves vary in shape, from roundish-obovate to oval, are somewhat thin in texture, glabrous, and of a bright shining green on the upper surface, crenately serrated on the edges, and on longish, smooth, marginal foot-stalks. The flowers are white when fully expanded and produced in May and June, in numerous terminal sessile cymes, on the short lateral branchlets. The berries are rather small, ovate, or roundish, and, when ripe, in September, nearly black, with a bluish tinge.

14. THE NAKED-CYMED VIBURNUM (*V. nudum*).—This forms a shrub, from 6 to 8 feet high, somewhat resembling the Plum-leaved one, but it has a more compact habit of growth. It is a native of North America, from Canada to Georgia, in swamps, particularly about Quebec, &c.; it is also found in Newfoundland, and was introduced in 1752. Its leaves are oblong ovate, bluntish at the point, angular at the base, quite glabrous, and with revolute, slightly crenulated, margins; the petioles are rather long, and beset with minute scale-like scurf or down. The flowers are whitish, and produced, in May and June, in rather large branching dense cymes or corymbs, on long, naked peduncles; the berries are globose, and, when ripe, in September, black. In mild seasons, this kind is more or less sub-evergreen, and there is a variety of it, named *Squamatum*, which has smaller leaves, and the young shoots, leaves, and petioles, more or less covered with minute rusty-coloured scales.

15. THE CASSINE-LIKE VIBURNUM (*V. cassinoides*).—This grows from 6 to 8 feet high, and has tetragonal branches, covered with scurfy dots. It is a native of North America, from New York to Carolina in swamps near the sea coast, and in Georgia in shady woods, and was introduced in 1761. Its leaves are either ovate-lanceolate, and acute at both ends, or oblong-obovate, obtuse at the apex and tapering at the base, crenately toothed or quite entire and sub-revolute on the edges, glabrous on the upper surface, covered on the under one with scurfy dots and on short scurfy foot-stalks. The flowers are white, and produced in June and July, in loose few-flowered sessile corymbs on the ends of the lateral shoots. The berries are ovate or roundish, shining, and of a bluish-black colour when

ripe, in September. Its synonyms are *Viburnum obovatum* and *punctatum*.

16. THE SMOOTH VIBURNUM (*V. lævigatum*).—This forms a stiff shrub, from 6 to 8 feet high, and has quite smooth tetragonal two-edged branches. It is a native of North America, in Virginia and Carolina, near the sea coast, and was introduced 1724. Its leaves are lanceolate, or oblong-lanceolate, remotely and unequally serrated on the upper part, wedge-shaped, and quite entire near the base, light green on the upper part and quite smooth on both surfaces. The flowers are white and produced in June and July, in loose, few-flowered, sessile corymbs. The berries are roundish and black when ripe, in September. Its synonyms are *Viburnum lanceolatum* and *corymbosum*. Its American name is Cassioberry bush.

17. THE SHINING-LEAVED VIBURNUM (*V. nitidum*).—This is a dwarf bush, which grows from 2 to 4 feet high, and has glabrous, four-sided, slender branches. It is a native of North America, in Carolina and Georgia, in sandy barren woods, and was introduced in 1758. Its leaves are small, linear-lanceolate, quite smooth, shining on the upper surface, slightly serrated or entire on the edges, and of a bright yellowish-green colour. Flowers, white, in few-flowered corymbs, and produced in May and June. Fruit, oval, and black, when ripe, in September. This forms a very neat and distinct shrub, and one that deserves to be more generally known than it is.

Evergreen Varieties.

18. THE COMMON LAURUSTINUS (*Viburnum Tinus*).—The Laurustinus, as is well known, is one of the most ornamental of evergreen shrubs; it is a native of the south of Europe, from whence it was introduced in 1596. The leaves are of a bright shining green, and the flowers, which are in flat corymbs, appear from November to April, and, in mild seasons, are often succeeded by small dark black berries. Of this there are the following varieties:—

THE VARIEGATED-LEAVED COMMON LAURUSTINUS (*V. Tinus variegatum*).—This only differs from the common form in having a portion of its leaves variegated with pale yellow.

THE HAIRY-LEAVED LAURUSTINUS (*V. Tinus hirtum*).—This is more hardy than the common kind, and is a native of Spain and Portugal. Its leaves are oval-oblong, hairy beneath and on the edges, and the flowers, which appear in the autumn, continue all the winter. There is a variegated form of this, which has a portion of the leaves of a golden-yellow colour.

THE SHINING-LEAVED LAURUSTINUS (*V. T. lucidum*).—This is a native of Algiers and Mount Atlas, and is less hardy than the preceding. Its leaves are oval, smooth, and of a deep shining green colour above. The cymes, as well as the flowers, are larger than those of the common kind, but seldom appear till the spring, and, when the winters are severe, the flowers are killed or never expand, unless in very sheltered places. Of this kind there is a variegated variety.

THE TWIGGY-BRANCHED LAURUSTINUS (*V. T. virgatum*).—This forms a somewhat erect fastigate bush, from 4 to 6 feet high. It is a native of Italy, particularly about Rome and Tivoli. Its leaves are oblong-lanceolate, pilose on the margins and principal veins on the under side, and the shoots erect. Of this variety there is, also, a variegated form.

19. THE CANARY ISLANDS LAURUSTINUS (*V. rugosum*).—This forms an erect dense bush, from 4 to 6 feet high, and has rigid, hairy branches. It is a native of the Canary Islands, in woods, and was introduced in 1795. The leaves are broadly-ovate, wrinkled on the upper surface, and hairy all over. The flowers are white, and produced from December to March, in rather large, open, bracing, terminal corymbs. The berries are ovate-oblong, and of a purplish colour when ripe. Its synonyms are *Viburnum rigidum* and *strictum*. This differs from the common Laurustinus in the leaves being hairy all over. It is too tender for the open border, but makes a fine display when planted against a south wall.

20. THE JAPANESE LAURUSTINUS (*V. suspensum*).—This forms a fine round dense bush, from 4 to 6 feet high, and has rather drooping and slender branches. It is a native of Japan, where it is called "Awa-fuki, and was introduced, in 1841, by Messrs. Rollisson, of Tooting. Its leaves are opposite, rather large, broadly-ovate, crenate, and rounded at the point, somewhat waved on the margins, smooth, and of a bright uniform

green above, strongly veined beneath, and rather thin in texture. The flowers are greenish-white, with the tube of the corolla, rather more than a quarter of an inch long, and cylindrical, and the limb divided into five blunt lobes, shorter than the tube; they are produced freely in February and March, in rather large, drooping, terminal compact cymes. It is rather tender for planting in the open border, but makes a fine plant for training against a wall. Its synonyms are *Viburnum Awa-fuki*, and *japonicum*.

21. THE SWEET-SCENTED CHINESE VIBURNUM (*V. odoratissimum*).—This forms a fine robust bush from 4 to 8 feet high, and in its general appearance greatly resembles the common Laurel. It is a native of China and Japan, and was introduced in 1818. Its leaves are large, elliptic-oblong, acuminate, leathery in texture, almost entire or sub-dentate with revolute margins, glabrous, of a deep shining green above, pale beneath, and nearly as large as those of the common Laurel. The flowers are white, very fragrant, and produced in February, in large thyrses, having opposite branches, trichotomously pedicellate. The berries are oblong, crowned by the calyx, and one-seeded, and, when young, of a rich red colour, but, when ripe, blackish and shining. This *Viburnum* is too tender for planting in the open border, but makes a fine evergreen for training to a wall. Its synonyms are *Viburnum sinense* and *Coffea monosperma*.
GEORGE GORDON, A.L.S.

Hedges.—In addition to the garden-hedges mentioned by your correspondent the other day, there are several plants suitable for this purpose, and not used generally in this country. In the Casino, at Florence, are small hedges, about 4 feet high and the same in thickness, dividing the carriage-drive from the foot-passengers' walk. These are of three different kinds—some of Mahonia (*Berberis Aquifolium*), which has a beautiful effect, showing here and there a crimson leaf; the other two are of *Euonymus japonicus*, one the common form, the other the variegated. In the south and west of Ireland one of the most striking of hedges is the common Fuchsia. I am myself trying *Cupressus macrocarpa* as a hedge-plant, and feel confident that it will bear clipping well, and in four or five years will form a dense and good-coloured hedge, 8 or 9 feet high. I am surprised to hear that Yew suffers from the shears if often used, having seen in Aberdeenshire a flower-garden, the beds of which were all edged with Yew about 8 inches high, and clipped square as a wall; and I was informed that they had been the same for ten years. The effect was good, the Yews being of a richer shade than Box, which, at a distance, they somewhat resembled.—J. H. W. T.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Conifers for Smoky Towns.—Mr. Bullen, Curator of the Botanic Gardens, at Glasgow, informs us that he finds *Thuja Lobbi* to be the best of all Conifers to withstand smoke. Next to this come *Cryptomeria japonica* and *elegans*, *Arancaria imbricata*, and *Cupressus Lawsoniana*. These are what succeed best in the neighbourhood of Glasgow.

Twelve Flowering Shrubs for a Small Lawn.—Double Variegated *Althæa*, Double white Almond, *Deutzia crenata* fl. pleno, *Spiræa Reevesii* robusta, *Weigela nivea*, *Forsythia viridissima*, *Hydrangea paniculata*, *H. grandiflora*, Japan Quince, large-flowered white Lilac, dark crimson Quince, *Prunus trilobata*, and *Pyrus Malus floribunda*.—G. ELLWANGER.

The Pinon (*Pinus edulis*).—In the upper portion of what is termed Williams' Canon, are a considerable number of the Pinon (*Pinus edulis*). I climbed a number of these trees, and examined the foliage from the ground to the summit, and find all the forms in the same tree which characterise *Pinus Fremontiana*, *P. monophylla*, and *P. edulis*; and have no doubt that these three so-called species are really but one.—Mr. MEEHAN.

New Trees.—Up in Colorado, in what is called Williams' Canon, is the only tree I have ever seen of the Elder-leaved Mountain Ash (*Sorbus sambucifolia*), which will prove a great addition to our ornamental trees when introduced to cultivation. The berries are smaller, and of a deeper orange than those of the common American Mountain Ash. In Engelmann's Canon, the long-beaked Hazel Nut (*Corylus rostrata*) abounds; which, I believe, none of us met anywhere else in the Rocky Mountains.—Mr. MEEHAN, in *Gardeners' Monthly*.

The Yellow Winter Jasmine.—Passing some cottages near Croydon the other day, I was pleased to see two of them most gracefully draped with this winter-flowering shrub, the shoots all drooping and densely laden with clearly coloured perfectly-opened flowers. Their condition suggested the thought that the common way of nailing this precious winter-bloomer too primely to the wall, spoils its beauty. After being sufficiently secured to the wall the shoots should then be allowed to droop freely down. Thus trained it becomes on the warm side of a house, a unique object in winter.—R.

When to take Cuttings of Variegated Hollies.—I should feel much obliged if you would kindly tell me when I should do this, and, also, how I should afterwards treat them?—B. F. [Cuttings of Variegated Hollies, made in autumn, of the ripened summer shoots, and planted in sandy soil in a shady border, covered with a hand-glass, will root freely in the following spring, and will be ready for transplanting into nursery-beds in the following October, where they should remain for two years. They should then be set out in lines sufficiently far apart to give room for fresh growth.—ED.]

THE FRUIT GARDEN.

RASPBERRIES ON WIRE TRELLISES.

I FIND that Raspberries, when trained on trellises, yield more fruit than when tied to stakes, and they also have a neater appearance. I train mine on a wire fence, which consists of three galvanised wires stretched horizontally, and supported by upright posts. The wires are fastened at each end by means of screws, and to the intermediate posts by staples—a kind of fence which may be put up by any ordinary labourer. The stools are planted 2 feet apart in the rows; the canes are trained vertically, 5 inches from each other, and their tops are bent over the fence about 1 foot, which allows but a very small portion to be taken off in pruning. I may mention that it is off this bent part of the top we get our finest fruit, both as to quality and quantity. The rows are 6 feet apart, and they run from north to south. The soil here is loam, resting on marly clay, which is wet and cold, on account of the River Thames, at high water, coming up to within a few feet of the rows. I never dig between my Raspberries; they are simply mulched with good cow manure, which keeps their roots near the surface. In autumn, the surplus rods are cut out, in order to admit light and air to the remaining ones; and we run twine along from one end of the trellis to the other, for the purpose of keeping the canes up to the wires. In November they are gone over again, when the old rods are removed, and the canes for the ensuing year's crop tied in. This is accomplished by one man holding them in their proper position, while another ties them to the wires, and, in this way, it is surprising how much work two men can get over in a day. We have thus no trouble with stakes, and our Raspberry fence is always admired. I believe, too, that the longer the plants remain in one place the stronger the canes become, provided the system is carried out properly; and, under it, we always get strong canes, which bear good crops.

D. S. GILLET, *Court Garden, Great Marlow.*

Flavour of Pines in the Winter Season.—Some years ago I ventured to assert my opinion on this subject. I then stated that the Black Jamaica was the prince of winter Pines, and since that time I have grown and tasted some scores, and now see no reason to alter that opinion; within the last two months I have had opportunities of more fully testing their different flavours. The smooth-leaved Cayenne, certainly a noble-looking fruit to look at, I pronounce third-rate as to flavour. The different varieties of Queens form better summer than winter Pines, in consequence of their pips not swelling evenly, but still we have an exception in the Thorsby Queen, which certainly does swell better than any other with which I am acquainted. This variety has one great fault, in having such a small crown. Flavour, first-rate. In the prickly Cayenne we have much to admire, when it ripens off regularly, but, unfortunately, the lower pips are generally greatly in advance of the top ones; this, however, happens more in summer than in winter. I have this day tasted one, as well as fruits of Charlotte Rothschild and Black Jamaica, and I pronounce it to be inferior in flavour to both. This I should set down as second-rate. Black Jamaica is a truly fine yellow-fleshed Pine, while both the Cayennes are white, and the flavour delicious. The fruit has also a good crown, and at all seasons swells well. I award this a first-class certificate, which, in my estimation, it well deserves. Charlotte Rothschild has a commanding appearance, and its flesh is not so white as that of the Cayenne. This I should pronounce barely second-rate in flavour.

—R. GILBERT, *Burghley, Stamford.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Standard Apricots.—I think the Apricot may be successfully grown as a standard in the south of England. I have seen a good standard tree at Little Comberton, near Pershore, which bore good crops.—W.

The Loquat out of doors in Buckinghamshire.—We have several plants of the Loquat (*Eriobotrya japonica*) out of doors on a south wall here, and notwithstanding the frosts which we have had, they are looking well.—D. S. G., *Great Marlow.*

Figs and Pigs.—A newspaper in Southern California advises greater cultivation of the Fig tree, because the fruit is so good for hog-feed. An acre of Figs will fatten more hogs than an acre of Corn. All that is necessary is to stick a Fig-cutting in the ground, and in three or five months the plant will bear fruit—three crops a year—and in three years the tree attains the size of a twelve-year-old Apple tree.

Keeping Apples.—I sometimes query whether the old masters in pomology really knew everything, as they would have us think. Among other things, we were taught that moisture was the greatest possible evil to guard against. Now, in looking over my Apples, placed in a damp cellar, I noticed that the skins were wet, not merely moist, and yet they are sound; and, from present appearances, are likely to be for some time to come. Others, who are not "shining lights" in the horticultural world, tell me that if the temperature is preserved at a very low degree dampness is a decided advantage. How about this new idea? If it should prove to be a general law we shall certainly have less shrivelled specimens.—*Tribune.*

ANCIENT EGYPTIAN GARDENS.

THE Egyptians appear to have had great thought for the future. They knew that the existence of a nation is not eternal, and they wished that, after they had disappeared from the face of the earth, those who succeeded them should not be ignorant of what they had been. It was, doubtless, with this view that they erected the Pyramids, those enormous monuments which have so successfully resisted the wear of time, and on which they carved scenes both of public and private life. From these monuments we are able to learn something of the kind of gardens that existed in the time of the Pharaohs. These gardens were of two kinds, sacred and private, among which were the royal gardens, used only by the kings. These sacred gardens surrounded the best temples, which served not only as sanctuaries, but also as places of abode. In the enclosures were planted Palms and the Sycomore Fig-tree; they also contained large basins made of granite and porphyry, in which grew the Lotus, and in which swam sacred crocodiles. In these gardens also were kept the ibis, the ichneumon, and the najah, a formidable serpent, which the priests knew how to tame, also the varan, or monitor, a large lizard, which, according to the belief of the Egyptians, and which is still preserved by the Arabs of the present day, gives warning to people by whistling on the approach of wild animals, but more particularly on the approach of the crocodile. It rarely rains in Egypt; consequently, all the cultivation of the Nile valley depends on artificial irrigation. For only three months of the year can irrigation be dispensed with—that is, from the beginning of September to the end of November—as, during those months, the Nile is nearly full. The period of its greatest height is at the end of September. The manner of watering followed by the ancient Egyptians was very simple. They suspended their buckets or leathern bottles to the end of a balance-pole tied to the cross-bar of a low scaffold, the pole being weighted by a stone at the opposite end to give impetus to the lift. The water, when drawn, was put into jars or skins, and carried to the plants requiring to be watered. The gardens were looked after with a great deal of care; their contents were very varied, and the great number of useful and ornamental trees cultivated in them bears witness to the good taste of the Egyptians. In the tombs at Thebes, and other Egyptian towns, are found numerous sculptured representations of their gardens. We will only cite a royal garden, which was surrounded with bastioned walls. A canal, communicating with the Nile, was cut before the principal entrance, running parallel with the wall and the river. The entrance consisted of a raised portal, opening on a large avenue of fine trees. The lintels and pedestals of the gateway were decorated with hieroglyphic inscriptions, among which is the name of the prince, proprietor of this domain. On each side of the entrance are the lodges of the guards, and other servants, charged with the care of the garden; likewise a waiting-room for visitors, whose names had not been announced. These palaces had doors opening on the enclosures in which Vines were cultivated. On one side was a house of three storeys, surrounded with beautiful trees, offering an agreeable retreat for repose and refreshment. At a little distance from, and in front of this edifice, are seen two kiosques, or pavilions, on colonnades, half hidden among the trees and surrounded with parterres of flowers. The Vines, which occupy the middle of the garden, are surrounded by plantations of Date and Doum Palms, and there are four pieces of water, in which are cultivated many varieties of aquatic plants; they, also, furnish water for irrigation. Two squares on each side of the Vine garden are reserved for the cultivation of particular plants and fruits of superior quality. The two kinds of Palms that have been mentioned, held the first rank in the estimation of the Egyptians, not only on account of their beauty, but, also, for their great utility. The fruit of the Date Palm was to them, what it is now to the Arabs and modern Egyptians, a popular food. They used it fresh from the tree, when ripe, prepared with honey, or simply dried in the sun, and the stem, branches, and fibre, were converted into a variety of uses. The Sycomore Fig, varieties of the Pomegranate, Olive, Jujube tree, Almonds, Peaches, Myrtles, several varieties of Acanthus, the Lotus (*Nelumbium*), and the Papyrus or Paper plant, were also grown in these ancient gardens.

PETER WALLACE.

GARDEN OF AN ANCIENT EGYPTIAN TEMPLE.

THE GARDENS OF ENGLAND.

ALNWICK CASTLE GARDENS.

The Forcing Department.

THE glass structures in these gardens devoted to the forcing of Pines, Vines, Peaches, and Melons, are, with the exception of two or three succession Pine-pits, and a range of Melon-pits, made entirely of iron. The houses are curvilinear in shape, and heated seemingly in a most efficient manner; they are also kept in the highest state of repair. The Pine-stoves are five in number, besides several pits for suckers; the fruiting houses are really fine structures, admirably adapted for the work to which they are devoted, and, I have no hesitation in saying that the Pines they contain are grown to great perfection. The Queens, which are grown largely here, are all that could be desired, compact in habit, with a depth of colour in their leaves that shows the care and attention that are bestowed upon them. Charlotte Rothschild, Black Jamaica, Smooth Cayennes, and Prince Albert are also grown here to great perfection. The latter variety is much in favour; it is a fine handsome Pine, producing fruit from 5 lbs. to 6 lbs. in weight, of a reddish-yellow colour, with a small neat crown, melting and juicy, with a rich aromatic flavour. A neat trellis forms a sort of canopy over the back passages of the Pine-stoves, and Cucumbers are grown in great quantities upon these trellises. The passages are lofty enough to allow fruit from 30 to 35 inches long to depend from them without coming in contact with the visitor's head as he passes along. They all appeared to be of one variety—the Marquis of Lorne. We also observed a few very fine Bananas just ripening their fruit. The Vineries here—six in number—are all, I believe, devoted to the growth of late summer or autumn Grapes for winter use. The borders of the whole range have been lifted or renewed within the last six or seven years, and the success of this operation is very evident in the exceeding fine crops of Grapes we saw in those houses, two of which were entirely occupied by Black Hamburgs. In regularity of crops, size of berries, and depth of colour, they were all that could be desired. The next two houses we found filled with a mixed collection, principally black varieties, including Lady Downes, Black Alicante, and Barbarossa; Mrs. Pince has also been worked into those houses, and showing very finely-finished bunches. The last two houses are wholly set apart to the growth of Muscats, including Cannon Hall and Escholata, which, strange to say, always set well here. The borders of these two houses have only been renovated last year, and the Vines were only lightly cropped; but, upon a former visit to this place we saw in these houses as fine a crop of Muscat Grapes as we have ever seen anywhere. The seedling Grape, referred to by us in our first paper on this place, is an early black variety, grows strong and robust, sets its fruit freely; the bunches are large, and the berries oval in shape, of good size, and keep as well as a Hamburg. I understand that the judges at the Glasgow International, in 1872, highly commended this seedling Grape. We were shown another black seedling Grape here, something in the way of Lady Downes, but larger in bunch and berry. Many who have tasted this Grape consider the flavour superior to the above variety. Altogether, this is a very promising Grape, and the entire stock of both the seedlings is in the hands of Mr. Ingram.

All the Grapes grown here are upon the short spur system, which may, in some measure, account for the regularity in the size of the bunches. The range of glass devoted to Peaches is divided into three compartments. All the fine old sorts are here in force, laden every year with excellent crops of fruit of very superior quality. Melons are grown here very extensively in forcing pits, and upon dung-beds. The green-fleshed varieties preferred are Basset's Seedling, Heckfield's Hybrid, Suttons' Prince of Wales; the other varieties including Golden Queen, Ward's Netted Scarlet, and Malvern Hall. Strawberries are also forced here in quantity, but not very early in the season, Keen's seedling seems to be the sort preferred for this purpose.

A large and elegant conservatory of recent erection, 100 feet by 30 feet, stands at the north end of the flower garden; the lofty roof is supported by a double row of pillars, which are

festooned with fine creepers, amongst which we noticed *Lapageria rosea*, *Tacsonia Van Volxemi*, *Bigonias*, and *Habrothamnus* of sorts between each pair of pillars. Along the front side a semicircular recess is formed, an arrangement which takes away from the flat stage that sameness which would otherwise have been unavoidable in such a width of flat surface. Along the back of the house the stage rises at a sharp angle, and it is always kept well filled with large well-grown specimen plants in bloom in autumn and winter. We saw about 400 *Primulas* in preparation for this purpose, the strain seemed to be one of the finest we have seen; almost every shade of colour was represented amongst them. Nearly an equal number of *Cinerarias* were in readiness for the same purpose. Just outside the boundary of the flower garden stands a span-roofed house 100 feet by 16 feet. One half of this house is filled with bedding and soft-wooded plants; in the other half we noticed a lot of fine specimen and half specimen Heaths, Azaleas, *Epacris*, &c.; close beside it stands a lean-to house, 40 feet by 16 feet, which is filled with a very fine collection of Ferns. In the same block stands another span-roofed house 100 feet by 16 feet, in two compartments. This house is filled to overflowing with specimen and half specimen plants suitable for table decoration. We observed here a small collection of Orchids, which are growing larger every year. Altogether this is a very interesting house, from the quantity of plants that have found a place in it. A small propagating-house completes the list of glass structures, together with framing, which is very extensively carried on here.

The Kitchen Garden.

These, including a small nursery ground, are about 7 acres in extent. They seem in a high state of cultivation, and the crops are abundant; the brick walls are not of very great extent, but they are certainly the best finished walls we have seen, and the trees upon them are models of perfection. As there are no glass structures against them the whole of the south wall is devoted to Peaches and Apricots. The fruit-trees along the borders are trained in the cup shape, very dwarf, and are annually laden with excellent fruit. Two orchards, which have undergone a thorough renovation, are bearing fine crops of Apples; one of them is specially interesting from the fact that, it occupies a part of the dry moat that surrounded the castle on the south-western side, close beside it there is still standing a part of the wall that enclosed the ancient kitchen-garden belonging to the castle. This relic of the past is, I believe, to be removed, in order to enable his Grace the Duke to carry out, more fully, his extensive alterations around this interesting place.

The Gardener's House

Stands very conveniently in the centre of the grounds; as a matter of necessity, it has been built low, but it is, nevertheless a roomy and comfortable house, replete with every convenience, the gardener's office, store, and fruit rooms join it. These have all been recently erected upon the most convenient and improved principle. The fruit-room is especially worthy of notice; it is 30 feet by 18, and is warmed and ventilated upon the best principles; the windows are double; in the false roof, Heather has been laid to a depth of several feet as a non-conductor of heat; indeed, everything has been done here that art or science could suggest. The same may be said of the gardener's office and store-room.

The Park

Encloses within its extensive boundary a rich variety of natural beauty. The Alne runs through its extensive length, shaded in many places by over-hanging rocks and pendent trees, the higher grounds being sheltered by extensive Fir woods, where the purple Heath in Autumn contrasts well with the great Ferny brakes that intermingle with it. The lower grounds are rich in pastoral beauty, and the two fine old mediæval ruins, along with other historical associations, makes this park extremely interesting to the visitor, who cannot help observing that, as he strays through the gardens and park, the sky-line, in one direction, is broken by the picturesque battlements and towers of the noble castle. J. T.

THE KITCHEN GARDEN.

THE VARIETIES OF THE GARDEN PEA.

(From the *Journal of the Royal Horticultural Society*.)

Division I.—Frame Peas.

Ripe seed, white, almost round, small, smooth, and occasionally pitted. Foliage, pale green, but not blotched.

Dillistone's Early (*Carter's First Crop*; *Clarke's Rapid Prolific*).—The plant is of a slender habit of growth, produces a single stem 2 feet high, and bears on an average from seven to nine pods. The pods are generally single, but occasionally in pairs, almost straight, and containing seven Peas in each. The seed, when ripe, is white. Sown on February 23. The first flower opened May 10; and the plants were in full bloom on the 16th. Slats appeared May 24; and the pods were fit for use on June 9. This is one of the earliest Peas known, about three or four days earlier than Sangster's No. 1, which has hitherto been regarded as the earliest variety. A striking feature of Dillistone's Early is, that its changes take place all at once. It blooms in a mass; its pods all appear together, and the whole crop is ready to be gathered at the same time. The pods are considerably smaller than those of Sangster's No. 1.

Sangster's No. 1 (*Dickson's First and Best*; *Daniel O'Rourke*; *Dickson's Climax*; *Early Caractacus*; *Washington*; *Taber's Perfection*; *Hooper's Early Rival*).—The habit of this variety is similar to that of the preceding, but it grows somewhat taller, being about 2½ feet high. Each plant bears from eight to ten pods, which are 2½ inches long, and upwards of half an inch wide, quite straight, and containing seven and frequently eight Peas in each; they are generally produced singly, but occasionally in pairs. Sown on February 23. The first flower opened May 12; and all were in bloom May 24. Slats appeared May 27; and the pods were ready for use June 12. The varieties which appear as synonyms exhibited slight variations as to character, some stocks being more pure and better selected than others, thus presenting in the mass a different aspect from the others. Caractacus produced fully the largest pods, and had a distinctive look. Taber's Perfection was rather later and a little more robust. Daniel O'Rourke and Hooper's Early Rival were exceedingly strong in growth and very inferior stocks. It appears that Isherwood's Railway has of late years advanced in earliness and become a synonym of Sangster's No. 1. Seven years ago it was the same as Early Emperor.

Early Emperor (*Morning Star*).—Plant of a slender habit of growth, always with a single stem, which is 2½ to 3 feet high, and producing from eight to ten pods, which are from 2½ to 3 inches long, generally single, but sometimes in pairs, and become perfectly straight as they approach ripeness. They contain about seven good-sized Peas, which, when ripe, are white. The samples of Early Emperor grown last year in the garden were very inferior and degenerate stocks of the true variety, possessing more of the character of the old Double-blossomed Frame, being even more robust in growth, and with smaller pods. Sown February 23. The first flower opened May 21. In full bloom May 30. Slats appeared June 3; and the crop was fit for use on the 19th. Ruelle Michaux, a variety from France, is an inferior form of Early Emperor. The same may be said of Clamart, which has also a near resemblance to Double-blossomed Frame; it keeps on growing and podding, but it is not a desirable variety to cultivate. This is a taller grower and a heavier cropper than either of the two preceding, but, as an early variety, it is not to be compared with either of them.

Early Frame (*Double Nimble*).—In adopting the name "Early Frame," I mean to include all forms known under that name, whether they are called single or double-blossomed; for, in fact, there are none that are absolutely "single" or absolutely "double-blossomed." These expressions are not meant to indicate any peculiar structure of the flower as regards the number of the petals, but merely that the blossoms are produced singly or in pairs on the same peduncle. Great efforts have from time to time been made to preserve the single-blossomed character; and, notwithstanding the care that has been bestowed upon the selection, growers have hitherto failed in rendering it permanent. There is, however, no real advantage to be obtained even if that character were secured, for the supposed earliness of the single-blossomed Frame Peas is now far exceeded by other varieties that have been introduced of late years. The variety I shall now describe under the name of Early Frame is one received from Messrs Hurst & M'Mullen, under the name of Marshall's Double-blossomed Frame—a very excellent and carefully selected stock of Early Frames. The plant is 3 to 4 feet high, and has a single stem of rather vigorous habit of growth, more stout and robust than that of Early Emperor, and bearing from nine to twelve pods; but frequently as many as fourteen. The pods are produced either singly or in pairs, and contain seven to eight Peas in each. The ripe seed is white. This is decidedly the best form of Early Frame I have met with. Sown on February 23. The first flower appeared May 14. In full bloom on the 25th. Slats appeared May 28; and the crop was fit for use June 15.

Beck's Gem (*Tom Thumb*; *De Grace*; *Royal Dwarf*; *Nain Hatif Extra*).—This is the most dwarf-growing of all the varieties. It rarely ever exceeds a foot in height; the stem is of a stout habit of growth, and branches at every joint to within three or four of the top, producing from fourteen to eighteen pods. The pods are almost always borne in pairs, rarely singly; and are produced at every joint, particularly towards the top; they are smooth, of a dark green colour, and well-filled, containing from five to eight Peas, which are almost as large as Imperials. The ripe seed is somewhat ovate, and of a greyish-pearly colour. Sown

February 23. The first flower appeared May 19. In full bloom May 25. Slats appeared on the 28th; and the crop was fit for use on June 17. This is a very excellent Pea for forcing, and for early sowing under walls or other shelter. It is remarkably prolific, and cannot but be of great use in small gardens where sticks cannot be conveniently obtained or made use of.

Early Ringwood (*Ringwood Marrow*; *Essex Rival*; *Flanagan's Early*; *Beck's Marrow*).—Plant, with a moderately vigorous habit of growth, 3½ to 4 feet high, not branching. The pods are single or in pairs, in about equal proportion; they are produced from within a foot of the ground at every joint, even to the extremity, and contain from six to eight large Peas. Ripe seed, white. Sown February 23. The first flower opened May 23. Was in full bloom on the 30th. Slats appeared June 2; and the pods were ready to gather on the 17th. Essex Rival, as grown in this trial, is an inferior stock of Early Ringwood, being later and with smaller pods.

Auvergne (*White Sabre*; *White Scimitar*).—This is, without doubt, the best second early of the Frame class in cultivation. The plant is of moderately strong habit of growth, 4 to 5 feet high, and bears from twelve to fifteen pods. The pods are generally single, and sometimes in pairs; when fully grown they are 4½ inches long, and over half an inch broad, tapering towards the point, and very much curved. They contain from nine to twelve Peas, which are very closely compressed, and are of the size of Early Frames. Even the small pods contain seven to nine Peas in each. Ripe seed, white. What was grown in the garden last year for Auvergne was a spurious stock, and resembled, and seemed intermediate between that variety and Dickson's Favourite, and inferior to both. It was quite unworthy of the name of Auvergne. Sown February 23. The first flower appeared May 28. Was in full bloom June 8. Slats came June 11; and the crop was fit for use on the 21st.

Glory of Cassel.—An indifferent mixture of Auvergne and Dickson's Favourite, with smaller but well-filled pods; pale green in colour; plant less robust, and about two days earlier.

Leopold II.—Resembles Early Ringwood, the foliage and pods being of the peculiar pale green colour which that variety possesses; pods, long, narrow, nearly straight, very badly filled, the middle Pea in each pod being wanting; quite worthless. Sown February 23. First flower opened May 25. Was in full blossom May 30. First slats appeared June 2, and were fit for use June 19.

Bishop's Long-podded Dwarf.—Plant, robust, branching close to the ground, about 2½ feet in height, producing from twelve to sixteen large broad pods, of a pale green colour, which contain from seven to eight large Peas. A fine-looking Pea, and a great cropper. Sown February 23. First flower opened May 21. Was in full flower May 30. First slats appeared June 3. Fit for use June 24.

American Early Comet.—A later and inferior variety of Bishop's Dwarf.

Dwarf Waterloo Branching.—Resembles in every respect Bishop's Long-podded Dwarf, but two days earlier.

Carter's Farmer's Prolific.—Resembles Early Emperor in general appearance. It is very strong, robust, and wonderfully prolific, producing from fourteen to sixteen pods, generally in pairs, on each stem; pods narrow, very closely filled, containing about six or seven small Peas. Height 5 to 6 feet. Sown February 23. First flower appeared May 26. Was in full blossom June 3. First slats appeared June 5, and were fit for use June 20. This is a distinct Pea, more suited for the farm than the garden.

Nabob (Laxton's).—Cross between Little Gem and Laxton's Prolific Long-pod; plant of strong and robust growth, with large deep-green foliage; height, 18 inches to 2 feet; pods, long, curved, well filled, of a deep-green colour, containing from seven to nine medium-sized Peas, of a pale green colour. The pods are produced in pairs from ten to twelve on each stem. It is the largest and most handsome early dwarf round white Pea, and very productive, most nearly resembling in appearance Dwarf Waterloo Branching, only with larger pods and dwarfier. Sown February 23. First flowers opened May 27. Was in full bloom June 1. First slatted June 3. Fit for use June 24.

Dwarf Dutch.—Plant, robust, in growth resembling White Prussian, about 3 feet in height, sometimes branching, and producing from twelve to sixteen pods on each stem, in pairs. The pods are small, narrow, but very closely filled, of a deep green colour, containing about seven small Peas. Sown February 23. First flower opened June 3. Was in full flower June 11. First slats appeared June 15. Fit for use June 24.

Peabody.—Plant, bushy, branching, very neat and compact in growth, the leaves being rather small and numerous, of a bright colour; height, about 2½ feet; pods, rather narrow, small, but extremely well filled, of a fine deep green colour, containing from six to seven rather small Peas of but poor quality. A very productive sort, standing the dry weather well. This belongs to the white Prussian class. Sown February 23. First flower opened June 12. Was in full flower June 15. First slats appeared June 18. Fit for use June 29.

Crown (*Bunch*; *Cluster*).—This is a very distinct and singular Pea in the appearance of its growth. The plant is 4½ to 5 feet high, of moderately strong growth. The stem gradually increases in thickness from the root upwards, frequently to the thickness of one's thumb, when it becomes broadly fasciated, producing all the pods, twenty-four to thirty in number, in a bunch at the top of the stem. The pods are small, round, but well filled, in appearance like Emperor, containing from four to seven small Peas. Ripe seed, small, round, white. Sown February 23. First flower opened June 16. Was in full flower June 17. First slats appeared June 21. Fit for use July 1. This is more curious than useful, being poor in quality. It is frequently called the Mummy Pea.

Division II.—Marrow Peas.

Ripe seed, white, large, smooth, uneven, compressed, irregular or egg-shaped; skin, thick. Foliage, blotched.

Paradise Marrow (*Paradise Early Marrow*; *Excelsior Marrow*; *Champion of Paris*).—This is a rather strong-growing variety, 5 to 6 feet high, having generally a single stem, which is, however, occasionally branched, and produces from eight to ten pods. The pods are, for the most part, single, but sometimes in pairs, about 4 inches long, nearly three-quarters of an inch wide, and remarkably well filled with from seven to nine large Peas. Ripe seed, white, medium-sized, somewhat flattened and pitted. Sown February 23. First flower opened May 30. Was in full flower June 7. First slats appeared June 11. Fit for use June 24. This is a very excellent Pea, an abundant cropper, quite as early as Early Ringwood and Early Frame, and considerably earlier than Auvergne and Shilling's Grotto, to all of which it is in every respect greatly superior.

Dixon's Early Dwarf Paragon.—Plant, robust, from 2 to 2½ feet high, resembling Bishop's Dwarf. Stem, branching, producing from sixteen to eighteen pods, which are generally borne in pairs; they are of a fine deep green colour, but fill badly, and contain from five to six medium-sized Peas. Dried seed, large, white, flattened, indented. Sown February 23. First flower opened May 23. Was in full flower May 30. First slats appeared June 2. Fit for use June 24.

Harrison's Perfection.—Plant with a robust habit of growth, having a thick succulent stem, 3 to 3½ feet high, and large dark green foliage. The pods are produced in pairs from every joint, averaging sixteen or eighteen on a plant, but they are very irregularly and badly filled, and contain only from four to six Peas. The Peas are large and thick-skinned. Ripe seed, white, medium-sized, and somewhat lentil-shaped. Sown February 23. First flowers opened May 16. Was in full flower May 26. First slats appeared May 29. Fit for use June 20. When this was first introduced, it was considered a great acquisition, as being an early dwarf Marrow Pea, and as such it would have deserved all that was said in its favour, provided it had not the very objectionable property of filling irregularly. The pods early assume the appearance of being ready for use, but when opened are found to contain half-grown Peas, four to six of which only come to maturity. It ripens at the same time as Prizetaker and Fairbeard's Nonpareil, and is some days later than Advancer, which has the same habit, is far more productive, and has the additional advantage of being a sweet wrinkled Pea. A very good cropping Pea, but with indifferently filled pods. Has long since been superseded.

Laxton's Prolific Long-pod (*Laxton's Prolific Selected*).—Plant of a robust and vigorous habit of growth, having large and pale-blotched foliage; height from 5 to 7 feet, producing from twelve to fourteen pods on each stem in pairs. The pods are very large, of a pale green colour, broad, much curved, and pointed, containing from seven to nine medium-sized Peas. Dried seed, white, indented. This resembles Prizetaker in general appearance, only being of a pale light green colour, instead of dark. This is the true variety, although most rarely to be met with, the other and commoner variety being but a bad stock of Prizetaker Green Marrow, and with the mixed coloured seed of that variety. Sown February 23. First flower opened June 1. Was in full flower June 5. First slats appeared June 11; fit for use June 25.

Thurston's Reliance.—The plant grows to the height of 6 or 7 feet, and is very strong and robust. The stem is simple, and bears, on an average, from ten to twelve pods, which are generally single, but occasionally in pairs, and from 3½ to 4½ inches long. They are broad and flat, shaped like the pods of the Blue Scimitar, and contain from seven to eight very large Peas. Ripe seed, white, large, unevenly compressed. This is a very distinct and very useful Pea, an abundant bearer, and the pods are of a fine deep bright green colour, which is a recommendation to it when grown for market. It comes in at the same time as the Auvergne and Shilling's Grotto, but it is of a more tender constitution, for, during the past summer, while the pods of these varieties filled well, those of Thurston's Reliance did not contain more than six to seven matured Peas; a character, however, which it does not exhibit in ordinary summers. What was grown in the garden last season for Thurston's Reliance proved to be small-podded, worthless stocks of Victoria Marrow.

Victoria Marrow (*Gibbs's Defiance*; *The Rector*).—This is also known by the names of Waterloo Marrow, Giant Marrow, Wellington Royal Victoria, and Tall Marrow. The plant is of a strong and vigorous habit of growth, having a simple stem from 6 to 7 feet high. The pods are produced near the top of the stem, sometimes single, sometimes in pairs in about equal proportion, and contain from five to seven very large Peas. Ripe seed, white, large, uneven, and roundish. Sown February 23. First flower opened June 8. Was in full flower June 13. First slats appeared June 16. Fit for use June 29. Extremely vigorous in growth, quite fresh and green when Dixon's Favourite was dead.

Princess Royal.—A very excellent cropper; pods, large full, broad, pale green in colour, and very handsome. Sown February 23. First flower opened June 1. Was in full flower June 6. First slats appeared June 9. Fit for use June 25. It is very doubtful if this is the true Princess Royal of Dr. McLean.

Division III.—Green Marrows.

Ripe seed of a mixed white and olive colour, either small, round, and pitted, or large, irregular, and uneven. Foliage, dark green and blotched. Pods, dark bluish-green, very glaucous.

William the First (Laxton).—A new hybrid raised by Mr.

Laxton. The plant is from 4½ to 5 feet high, somewhat slender in growth, like the Early Frame class; stem, simple, and producing from fourteen to sixteen pods, generally single, but frequently in pairs. The pods are long and very handsome, of deep green colour, covered with a thick bloom like Prizetaker, much curved and pointed like the Auvergne, and contain from seven to eight good-sized Peas of a deep green colour. The ripe seed is small, round, indented, of a mixed white and olive-green colour, like Prizetaker. Sown February 23. First flower opened May 12. Was in full flower May 22. Slats appeared May 24; and pods fit for use June 14—two days later than Sangster's No. 1, and nine days earlier than Prizetaker. This is the earliest Green Marrow Pea, and was awarded a first-class certificate.

Unique (Laxton).—A cross between Laxton's Prolific and Little Gem. The plant has the habit of Tom Thumb and Little Gem, and is moderately robust, from 1 foot to 1½ high; stem, branching; producing from eight to ten pods on each, generally in pairs. The pods are rather long, broad, slightly curved and pointed, of the scimitar-shape, of a fine green colour, containing from six to eight bright green Peas in each. Ripe seed parti-coloured. Sown February 23. First flower opened May 15. Was in full flower May 24. First slats appeared May 27. Fit for use June 19. A fine long-podded and prolific early dwarf Pea, which received a first-class certificate.

Prizetaker (*Bellamy's Early Green Marrow*; *Rising Sun*; *Prolific Long-pod*—*Green seed*; *Carter's Hundredfold*). These are all forms one of another, without any marked distinction.)—The plant is 4½ to 5 feet high, of a vigorous habit of growth. The stem is sometimes simple and sometimes branched, and produces from twelve to eighteen pods. The pods are in pairs, very rarely single, and of a deep bluish-green colour, covered with a thick and distinct bloom; they contain six to seven large Peas in each, which are of a dark bluish-green. The ripe seed is small, round, and of a mixed white and green colour. Sown February 23. First flower opened May 28. Was in full flower June 3. First slats appeared June 8. Fit for use June 23. This is a very excellent Pea, and an abundant bearer, but I cannot perceive any great difference between it and Bellamy's Early Green Marrow, which I grew in a collection for the purpose of comparison in 1853, and a very excellent form of which was grown by Messrs. Noble, Cooper, & Bolton, under the name of Noble's Early Green Marrow. In that year the latter was sown as late as the 5th of April; bloomed on the 15th of June; slatted on the 21st; and on the 8th of July the crop was ready for use.

Laxton's Prolific (*Leicester Defiance*. Mixed green and white seed.)—This consisted of mixed stocks of inferior Prizetaker and Laxton's Prolific (true).

Laxton's Supreme.—Plant, robust, in appearance and character like Prizetaker, but having the foliage and pods of a much paler green, which marks their distinction; pods, very large, long, broad, but scarcely so well filled as they appear, containing from seven to nine large Peas. Olive green, ripe seed indented. A large and very handsome Pea. Sown February 23. First flower opened May 30; Was in full flower June 4. First slats appeared June 9. Fit for use June 24.

Superlative (Laxton).—A cross between Ne Plus Ultra and a hybrid of Supreme; plant exceedingly strong and robust, having a strong succulent stem, from 7 to 8 feet high, and large broad pale green foliage; stem generally simple, producing from fourteen to sixteen pods, mostly in pairs. The pods are very large, about 7 inches long, and somewhat irregular in form, broad, much curved and pointed, of a pale green colour, containing from seven to nine large Peas of a pale green colour and of no particular flavour. Dried seed flattish, parti-coloured. Sown February 23. First flower opened May 30. Was in full flower June 5. First slats appeared June 10. Fit for use June 26. The largest-podded Pea, exceedingly handsome in appearance. The pods, however, do not fill to nearly their full extent, many of them being only half-filled. Received a first-class certificate.

Mossy-podded (*Australian*; *Blankney Marrow*).—Plant, 6 to 7 feet high, of strong and vigorous habit of growth, with deep-green foliage, which is maintained healthy for a lengthened period; stem, generally simple, producing from twenty to twenty-four pods, mostly in pairs. The pods are long, slightly curved, full, and round in form, of a bright green colour, and frequently covered (especially where slightly shaded) with minute excrescences in appearance like Moss, which give the pods a rough appearance; they contain from seven to eight medium-sized Peas, closely packed together, which are of a deep green colour, and of poor flavour. Dried seed, parti-coloured, green, half-wrinkled. Sown February 23. First flower opened June 18. Was in full flower June 20. First slats appeared June 24; fit for use July 3.

The Baron (Laxton).—A hybrid Green Marrow, raised by Mr. Laxton; plant of moderately robust growth, not much branched; height from 5 to 6 feet; pods, produced in pairs, from ten to twelve on a stem, very large, from 5 to 6 inches long, curved and pointed, of a fine deep green colour. Very much like Superlative in appearance, but more than a week earlier. They contain from ten to twelve large Peas of a fine green colour. Ripe seed, blue, indented. Sown March 21. Fit for use June 27. Awarded a first-class certificate.

Division IV.—Prussian Peas.

Ripe seed, small, almost round, and smooth. Skin, blue. Foliage, dark green, blotched.

Harbinger (Laxton).—A cross between Dillistone's Early and Alpha. The plant has the habit of Dillistone's Early; stem, from 2½ to 3 feet, simple, producing from seven to eight pods singly. The pods are small, rounded in form, slightly curved, very tightly filled, of a light green colour, and contain about six fair-sized Peas of a fine colour and

good flavour. Ripe seed, small, round, blue. Sown February 23. First flower opened May 9. Was in full flower May 15. Slats appeared May 21. Fit for use June 6. The earliest Pea in the collection, being three days earlier than Dillistone's Early, and six days earlier than Sangster's No. 1. Received a first-class certificate. Last season (1873) this Pea was not so much in advance of other early sorts.

Eastes's Kentish Invicta.—The same as Harbinger in every other respect, but seven days later. Sown February 23. First flower opened May 14. Was in full flower May 25. Slats appeared May 27. Fit for use June 13.

Carter's First Crop Blue.—Has the habit of Burbidge's Eclipse, but dwarfier. Height, 18 inches to 2 feet, robust, producing from eight to nine pods on each stem, single and in pairs. The pods are rather short, but broad, very slightly curved and bluntly ended, of a light green colour. They contain from five to six Peas of medium size, and do not fill out well at all times. Ripe seed, large, round, blue. Sown February 23. First flower opened May 22. Was in full flower May 26. First slats appeared May 30. Fit for use June 19.

Woodford Marrow.—Plant of a strong and robust habit of growth, having very dark bluish-green blotched foliage, and a stem 3½ feet high, which is sometimes simple; but generally branched at about half its height from the ground. The pods number about eleven on a plant, and are produced singly or in pairs. When ready to gather, they are rather flattened; but, as they become ripe, they assume a roundish shape. They contain, on an average, eight Peas in each, which are of a very dark olive-green colour, rather thick in the skin, and very closely packed—so much so as to be quite flattened where they come in contact. Ripe seed is very dark blue. On account of its fine dark green pod, this is an excellent Pea to grow for market; but it is one that requires to be very carefully selected when grown for seed, as it has a great tendency to degenerate back to the Blue Prussian, from which it has evidently been raised. Sown February 23. First flower opened June 5. Was in full flower June 13. First slats appeared June 16. Fit for use June 27.

Green Noyon.—The plant has the habit of Blue Prussian, having a stem about 2½ feet high, with deep green foliage; pods, small, round, and very full, nearly straight, there being from eight to nine on each stem, generally in pairs, of a pale green colour, and containing from five to six small Peas. Ripe seed, round, light green, small, smooth. A worthless variety. Sown February 23. First flower opened June 12. Was in full flower June 14. First slats appeared June 16. Fit for use June 27.

Blue Prussian.—Plant not robust or strong in its habit, having a stem 3 feet high, which is sometimes branching, and with dark green blotched foliage. The pods are generally in pairs, from twelve to sixteen on each plant, and contain about seven closely packed Peas. The ripe seed is blue, small, and almost smooth. This is a very old and popular variety, much used for extensive culture in fields and market-gardens on account of its great fertility—a character which it maintains superior to any of the other blue Peas, most, and indeed all, of which during the past season have exhibited much less hardy constitutions. Sown February 23. First flower opened June 9. Was in full flower June 13. First slats appeared June 16. Fit for use June 30.

Evergreen (Laxton).—Plant 5 to 6 feet high. Habit of growth like Auvergne, with rather small pale green foliage. Stems, generally simple, producing from fourteen to sixteen pods in pairs. The pods are rather small, slightly curved, and bluntly pointed; very closely filled with from seven to eight medium-sized Peas. The Peas are of a bright green colour, tinged with dark green. Flavour, very inferior. Ripe seed of a deep green piebald colour. Sown February 23. First flower opened June 2. Was in full flower June 13. First slats appeared June 16. Fit for use July 1. A very inferior Pea.

Nimrod (Laxton).—Plant, slender; in the habit of growth and general appearance like Alpha. The stem is simple, 3 to 4 feet high, producing from seven to eight pods singly, which contain from six to eight Peas each, of a deep green colour. Pods, round, full, much curved, of a very deep green colour, resembling William I. Ripe seed, round, bluish-green, indented. Sown February 23. First flower opened May 10. Was in full flower May 21. First slats appeared May 26. Fit for use June 14.

Blue Peter (Carter).—The habit and growth are similar to that of Tom Thumb; height from 1 foot to 1½; pods, large, broad, of a fine green colour, from eight to ten being produced on each stem. They contain from five to six large Peas generally; but they frequently fill badly. Ripe seed, round, blue. Sown February 23. First flower opened May 19. Was in full flower May 27. First slats appeared May 29. Fit for use June 18. A larger form of Tom Thumb, with round blue seed. This received a first-class certificate.

Griffin (Laxton).—Plant, 3 to 4 feet high; habit, form, and colour of the pods resembling those of the Frame class. Stem, simple, producing from fourteen to sixteen pods, generally in pairs, containing from six to seven medium-sized Peas, of a pale green colour, tinged with darker green, giving them a very peculiar appearance. Flavour very inferior. Ripe seed, small, deep mottled green, indented. Sown February 23. First flower opened May 16. Was in full flower May 27. First slats appeared May 30. Fit for use June 21. An inferior variety.

Fairbeard's Surprise (Early Surprise).—The plant is a free but not robust grower, and always with a simple stem, which is about 5 feet high. The foliage is bright and not dark green, like the other varieties of this class. The pods are generally single, but sometimes in pairs, and are from eight to ten on a plant; they contain from seven to eight good-sized Peas. The ripe seed is somewhat oval, of a pale blue colour. This and Fairbeard's Champion of England were originally taken from the same pod, the former having a round, and the latter a wrinkled, seed. It is the earliest of all the round blue Peas, and very superior in every respect

to the following, which comes into use two or three days later. Sown February 23. First flower opened June 1. Was in full flower June 6. First slats appeared June 9. Fit for use June 24.

Harrison's Glory.—The only distinction between this and Harrison's Perfection is the blue-coloured seed, that of the latter being white; they differ in no other respect, being of the same height, equally productive of pods, which always fill very badly, and both come into use at the same time. Sown February 23. First flower opened May 26. Was in full flower June 5. First slats appeared June 8. Fit for use June 24.

Harrison's Royal Blue.—Plant resembling in its aspect Dancroft Rival, differing, however, from that variety in the stem, stipules and the pods being devoid of glaucousness, the leaves having the usual glaucous hue. This peculiarity gives it a very singular appearance. The plant is moderately robust, about 3 feet high, producing from fourteen to sixteen pods on each stem. The pods are short, broad, slightly curved, very badly and irregularly filled, containing only from four to five Peas in each, of very inferior quality. Ripe seed large, round, blue, flattened, and indented. Sown February 23. First flower opened May 21. Was in full flower May 27. First slats appeared May 30. Fit for use June 26.

Burbidge's Eclipse (Stubbs' Dwarf).—The plant is a dwarf but robust grower, from 18 inches to 2 feet high. The foliage is dark green, slightly blotched. The stem is always simple, and produces from ten to twelve pods, which are generally in pairs, rarely single. They contain from five to six Peas, which are of good size, and closely packed. The ripe seed is large, uneven, oval, and of a blue colour. This is the dwarfest of all the blue Peas, and is an excellent bearer. Sown February 23. First flower opened June 2. Was in full flower June 8. First slats appeared June 12. Fit for use June 25. Clipstone Hero is a somewhat taller and more robust form of this variety.

Mogul (Laxton).—A cross between Prolific Longpod and Little Gem; plant moderately robust, resembling Burbidge's Eclipse, and from 18 inches to 2 feet high; stem, branched, producing from eight to ten pods, generally in pairs. The pods are long, very full, rounded in form, much curved and pointed, of a beautiful green colour, containing from six to eight medium-sized Peas. Extremely handsome, prolific, but inferior. Dried seed, large, round, blue, indented. Sown February 23. First flower opened May 27. Was in full flower June 1. First slats appeared June 4. Fit for use June 25.

Fillbasket (Laxton).—A cross between Laxton's Standard and Supreme; plant very robust and vigorous, growing to about 3 feet in height; foliage, large, pale green, of a very distinct character; stem, branching, producing from twelve to fourteen pods on each, generally in pairs. The pods are very long, curved, closely filled, rounded in form, of a fine bright green colour, containing from seven to nine good-sized Peas of a fine green colour. Dried seed, large, light green, flattened. Sown February 23. First flower opened June 2. Was in full flower June 8. First slats appeared June 11. Fit for use June 26. A large very handsome, and prolific Pea, which received a first-class certificate.

Flack's Imperial (Flack's Victory; Flack's Victoria).—This variety, introduced about ten or twelve years ago as an improvement on Bedman's Imperial, appears now to represent the varieties formerly known as Blue Imperial and Bedman's Imperial, and deservedly so, for it is the only one of the name really worth growing, when true, and it requires careful selection to keep it so, from its tendency to degenerate into Blue Prussian. The plant is of a robust habit of growth, with a stem which is always branching, and generally about 3 feet high, producing dark green blotched foliage. The pods are from twelve to eighteen on a plant, generally in pairs, but frequently single, and contain from six to eight very large Peas, which are of an ovate shape, about half an inch long, and seven-twentieths broad. The ripe seed is large, irregularly oval, and dark blue. Sown February 23. First flower opened June 4. Was in full flower June 10. First slats appeared June 14. Fit for use June 25.

Bedman's Imperial.—Bedman's Imperial was the first improvement on the Old Blue Imperial, but it has now been for many years superseded by Flack's Imperial. Sown February 23. First flower opened June 3. Was in full flower June 9. First slats appeared June 11. Fit for use June 26.

Blue Scimitar (Blue Sabre; Scimitar).—The plant is a strong, robust grower, 2½ to 3 feet high, generally with a simple stem, but sometimes branching, and having dark green blotched foliage. The stem bears from twelve to eighteen pods, which are also of a dark green colour, and very much curved and flattened. They are produced generally in pairs, and contain on an average nine to ten Peas in each. The ripe seed is irregularly oval and dark blue. This is an old variety, and now very much grown by farmers and market-gardeners as a field crop, for the supply of the markets of large towns, the fine large dark green pods always commanding a ready sale. It is very prolific, and is, without doubt, one of the best varieties for culture on a large scale, but is one which is very liable to degenerate, and demands very careful attention to preserve a pure stock. Sown February 23. First flower opened June 7. Was in full flower June 14. First slats appeared June 14. Fit for use June 30.

Supplanter (Laxton).—A cross between Veitch's Perfection and Little Gem; plant, very robust and vigorous; height about 3 feet; foliage, deep green, like the Woodford Marrow; stems, branching, producing from fourteen to sixteen pods on each, in pairs; pods, very large, broad, scimitar-shaped, of a deep green colour, and containing from seven to eight very large Peas, which are of a deep green colour. Dried seed, very large, bluish-green, flattish, round, and sometimes indented. Sown February 23. First flower opened May 26. Was in full flower May 30. First slats appeared June 2. Fit for use July 1. A large, handsome, and very prolific Pea, which received a first-class certificate.

Division V.—Wrinkled White Marrows.

Ripe seed, white, compressed and wrinkled. Foliage, most frequently dark green and much blotched; but occasionally light green, and slightly or not at all blotched.

Pioneer (Laxton).—A cross between Dillistone's Early and Little Gem. Plant of the type of Sangster's No. 1, but with paler foliage, especially when in a young stage, which gives it a sickly appearance. Height from 3 to 3½ feet, producing from nine to ten pods on a stem, generally simple. The pods are of fine size, nearly straight, pale green, and contain from five to six Peas. Ripe seed, rather small, wrinkled, white. Sown February 23. First flower opened May 9. Was in full bloom May 18. First slats appeared May 22. Fit for use June 13. One day later than Dillistone's Early. The earliest white wrinkled Marrow, of fine quality, resembling Alpha, only differing in the colour of the seed.

Alexandra (Laxton).—A cross between Prolific Longpod and Advancer. Habit and general appearance of plant like the Frame class. Somewhat straggling, attaining a height of 4 to 4½ feet. The pods are produced singly from ten to twelve on each stem; they are large, somewhat curved, and contain from eight to nine fair-sized Peas in each, which are very closely packed. The colour of the plant throughout is a pale green. Ripe seed, white, slightly wrinkled. Sown February 23. First flower opened May 12. Was in full flower May 16. First slats appeared May 24. Fit for use June 12. Of the same earliness as Sangster's No. 1. A very early wrinkled Pea, of excellent quality when cooked.

Nutting's No. 1 (Carter's White Gem).—Plant very robust and vigorous, with pale green blotched foliage; height, 2 to 2½ feet, stem, branching, producing from eight to twelve pods in pairs on each, which are borne almost close on the ground; pods short, well filled, rounded in form, slightly curved and bluntly ended, of a pale green, almost whitish colour. They contain from six to seven large Peas in each, of a whitish green colour. Exceedingly sweet and excellent. Dried seed large, white, wrinkled. Sown February 23. First flower opened May 21. Was in full flower May 28. First slats appeared May 30. Fit for use June 18. A remarkably prolific and handsome dwarf Pea, flowering at the same time as Alliance, but coming into use three days before that variety.

Fairbeard's Nonpareil Marrow.—The plant is of a free, but not vigorous, growth, resembling the Early Frames both in habit and in foliage, the latter being light green and not blotched. The stems are branching, 3½ to 4 high, and producing twelve to fourteen very full and plump pods, which are generally in pairs, and contains six or eight closely packed Peas. The ripe seed is small, white, and wrinkled. This is an early and very productive Pea, and comes into use at the same time as the Early Frames and the Early Ringwood. The Peas, however, are small, and, as a wrinkled variety, it is now surpassed. Sown February 23. First flower opened June 3. Was in full flower June 11. First slats appeared June 14. Fit for use June 25.

Alliance (Eugenie; Evershed's Early Prolific; Early White Wrinkled Marrow).—Plant with a free habit of growth, having a succulent stem, and rather light green blotched foliage. The stem is simple, 3 feet high, and produces from twelve to sixteen pods, which are generally in pairs, and are produced at every joint. They are not well filled, and contain only five or six good-sized Peas in each. The ripe seed is white and wrinkled. This differs from Climax only in having the ripe seed white. When first introduced it was a valuable acquisition as being a tolerably early dwarf white wrinkled Pea, but it is now far surpassed in every way. Sown February 23. First flower opened May 21. Was in full flower May 27. First slats appeared June 1. Fit for use June 24.

Prince of Wales.—A finely selected stock of Alliance, a little later, and with better filled pods. Sown February 23. First flower opened June 1. Was in full flower June 5. First slats appeared June 8. Fit for use June 24.

Nelson's Vanguard.—Resembles in its general characters Alliance, but dwarfer than that variety, and with broader pods. It flowered, slatted, and came into use at the same time.

Rajah (Laxton).—A cross between Little Gem and Laxton's Prolific Long-pod. This is intermediate in form between Advancer and Little Gem. The plant has the appearance of the former, but is dwarfer. Height, 18 inches to 2 feet. The pods are borne in pairs, eight to ten on a plant. They are very long and much curved, very full, giving them a rounded form, and contain from eight to nine fair sized Peas in each. Dried seed, white, wrinkled, flattened. Sown February 23. First flower opened May 29; was in full flower June 4. First slats appeared June 7. Fit for use June 24.

Dean's Dwarf Marrow (Robert Fenn).—This somewhat resembles in its general appearance James's Prolific. It is, however, distinct from that variety, in the shape of the pods, they being more abrupt, and of greener colour. The plant is also dwarfer, not much exceeding 2 feet in height. It is remarkably robust and upright in growth. Ripe seed, large, green, wrinkled. Sown February 23. First flower opened May 30. Was in full flower June 4. First slats appeared June 6. Fit for use June 24.

Standard (Laxton).—A cross between Veitch's Perfection and Little Gem; plant, robust, branching; height, 3 feet; foliage, light green. The pods are borne in pairs, from fourteen to sixteen on each stem. They are very long, much curved, like Auvergne, rounded in form and pointed, closely filled, showing the form of the Peas through the pod, and of a light green colour. They contain from nine to eleven Peas in each, of large size, of a fine deep green colour, and excellent in quality. Ripe seed, white and green, wrinkled and flattened. Sown February 23. First

flower opened June 4. Was in full flower June 9. First slats appeared June 12. Fit for use June 25. A very handsome and prolific Pea.

Wonderful (McLean's).—Plant, resembling in its general character Alliance, but more even and regular, stem not so succulent; height, about 3 feet, producing from eleven to twelve pods on a plant, generally in pairs. The pods are large, very slightly curved and pointed, of a pale green colour. They are well filled, containing from six to seven large Peas of a light green colour. Quality excellent. Dried seed, rather small, very white, wrinkled. Sown February 23. First flower opened June 2. Was in full flower June 8. First slats appeared June 11. Fit for use June 26. Two days later than Alliance, and a much superior Pea.

Prolific (McLean's).—Resembling Wonderful in its general characters, but having much larger pods; height, about 3 feet, of strong and robust growth, producing from twelve to fourteen pods on each plant. The pods are large, broad, slightly curved and bluntly pointed, and contain from six to seven large Peas in each, which are unusually sweet and good. Sown February 23. First flower opened June 3. Was in full flower June 9. First slats appeared June 13. Fit for use June 28. This variety keeps long in fit condition for use.

British Queen (Rollisson's Victoria; Shanley Marrow; Hooper's Incomparable; Imperial Wonder (excellent stock); Carter's Leviathan (strong stock); McMillan's Queen of the Marrows; William's Emperor of the Marrows; Ward's Incomparable; Wonder of the World; Champion of Scotland; Queen of the Marrows; Thome's Royal Britain; Great Britain).—These are all forms, more or less selected, of the British Queen and Tall White Mammoth.—This is a free and robust grower, 6 to 7 feet high. The stem is generally single, but also sometimes branched when the seed has been sown thin, and then it is furnished with two or three laterals which are the same height as the main stem; pods, generally single, but occasionally in pairs, and are to the number of thirteen to eighteen on a plant; they contain five to seven very large Peas, some of which are more than half an inch in diameter. The ripe seed is white and wrinkled. British Queen is now an established variety, and justly esteemed as one of the best and most productive of the tall wrinkled Marrows. On a well-branched plant I have counted as many as thirty-one pods of all kinds, including those full-grown and those just formed; and, in a mild autumn, it is not unusual for it to continue growing, blooming, and podding as late as Christmas. I do not see any material difference between this and Tall White Mammoth, with the exception that the latter is two days earlier; the plants are exactly similar in habit, and are equally productive. Sown February 23. First flowers opened June 12. Was in full flower June 15. First slats appeared June 18. Fit for use June 30.

Challenger (Dean)—**Sussex Hero** (Wood & Son)—**Wrinkled White** (Chamberlain).—These proved to be good stocks of British Queen.

The Prince.—Intermediate in form between Veitch's Perfection and Premier; plant, robust and vigorous, much branched; foliage, rather small, deep green. The pods, which are produced in pairs, are smaller than Veitch's, of a pale green colour, showing the form of the Peas through, like Premier. It flowered, slatted, and was fit for use the same time as Premier. A very vigorous and prolific form of Veitch's Perfection, standing the dry weather well.

The Prince (Selected) (Dean).—No improvement on the old stock.

Dwarf Canada (Evershed's Marrow).—A somewhat taller and stronger-growing form of The Prince, coming into use a day or two later, but otherwise not distinct.

Premier (McLean's).—Plant, robust, but not producing so succulent a stem as Veitch's Perfection; foliage, smaller and deep green; pods, borne in pairs, from sixteen to eighteen on a stem. They are large, broad, pale green in colour, showing the form of the Peas through the pods, and contain about six or seven very large Peas of excellent quality. Dried seeds, small, green and white mixed. Sown February 23. First flower opened June 5. Was in full flower June 14. First slats appeared June 17. Fit for use June 30. An excellent, somewhat earlier and hardier Pea than Veitch's Perfection, of the same class.

Lincolnshire Defiance is very similar to Premier.

Bland's Defiance (Bland).—A selection from Premier, but no improvement.

Cowle's Wrinkled Marrow.—Plant, robust, resembling Premier in general characters; pods, long, curved, rounded in form, of a light green colour, containing from six to seven large Peas. Sown March 1. First flower opened June 5. Was in full flower June 11. First slats appeared June 19. Fit for use July 2.

Lynn's Wrinkled Marrow.—The plant is a robust grower, 3 feet high, and with dark green and much blotched foliage. The stem is simple, producing from twelve to fourteen pods, which are in pairs, and contain from six to eight Peas in each. The ripe seed is white, wrinkled, and with a black hilum, like the Egg Pea. This is a very hardy variety, and, as such, is grown rather extensively in the neighbourhood of some of the manufacturing towns in the north; but it is not a desirable sort. Sown February 23. First flower opened June 17. Was in full flower June 19. First slats appeared June 21. Fit for use July 1.

Knight's Tall White Marrow.—This is a strong and robust grower, 6 to 7 feet high. The stem is much branched, and keeps on growing and producing pods till late in the season. The foliage is dark green and much blotched. The pods are produced in pairs to the number of twelve to eighteen on a plant, and they contain from seven to eight Peas in each, which are very closely compressed. The ripe seed is white and wrinkled. Sown February 23. First flower opened June 11. Was in full flower June 15. First slats appeared June 10. Fit for use July 3.

James's Prolific (James).—A selection from Wonderful; plant robust; height, 3 feet; stem, strong and succulent, occasionally branched, producing from eight to ten pods on each, generally in pairs; foliage large, pale green, and much blotched; pods, very large, broad, nearly straight and bluntly ended, of a very light green colour, similar in that respect to Excelsior Marrow. They contain from six to eight very large Peas, of a pale green or whitish colour, of excellent quality. Ripe seed, large, white and pale green, wrinkled. Sown March 1. First flower opened June 13. Was in full flower June 16. First slats appeared June 19. Fit for use July 14. An extremely handsome Pea when growing, of firm and erect growth, the pods being well sustained from the stem, and nearly all being fit for use at the same time. This received a first-class certificate.

Dagmar (Laxton).—Plant, robust, branching; height, about 12 inches; pods, produced in pairs, full, rounded, curved, and pointed, of a pale green colour, from $3\frac{1}{2}$ to 4 inches long, and contain from seven to eight large peas of very fine quality. Very prolific. Ripe seed, white, wrinkled. Sown March 21. Fit for use June 20, at the same time as Sangster's No. 1. A very fine early dwarf wrinkled pea. Awarded a first-class certificate.

The Shah (Laxton).—Plant of the habit of Sangster's No. 1, simple; height, about 3 feet; pods, produced singly, but abundantly, very full, rounded, almost straight, or but very slightly curved, about 3 inches long, of a pale green colour, and contain from eight to nine very large peas, of very fine quality. Ripe seed, white, wrinkled. Sown March 21. Fit for use June 20, at the same time as Sangster's No. 1. An exceedingly fine early prolific white wrinkled pea. Awarded a first-class certificate.

Marvel (Laxton).—Plant of robust habit of growth, branching; height, 3 feet; pods, produced in pairs great abundance, very large, from 4 to $4\frac{1}{2}$ inches long, full, rounded, much curved and pointed, of a light green colour, and contain from nine to eleven very large peas, of very fine quality. Ripe seed, white, wrinkled. Sown March 21. Fit for use July 2. A remarkably handsome, large, and exceedingly productive white wrinkled Marrow. Awarded a first-class certificate.

Division VI.—Wrinkled Green Marrows.

Ripe seed, mixed white and olive; foliage, dark green and blotched; pods, dark dull green, very glaucous.

Dr. Hogg (Laxton).—A cross between Prolific Long-pod and Little Gem. It has the habit and type of Sangster's No. 1. Stem, simple, rather straggling; height, about $3\frac{1}{2}$ feet; pods, produced singly and in pairs, from ten to twelve on each stem. They are long, narrow, much curved and pointed, very well filled, of a beautiful deep green colour, like William the First. They contain from seven to nine medium-sized Peas, which are of a fine deep green colour, like Ne Plus Ultra. Very sweet and of excellent quality. Ripe seed, green, much wrinkled. Sown February 23. First flower opened May 15. Was in full flower May 24. First slats appeared May 27. Fit for use June 16. A very handsome Pea, of excellent quality. The earliest green wrinkled marrow, only four days later than Dillistone's Early, and two days later than Alpha. This received a first-class certificate.

Ne Plus Ultra.—*Cullingford's Champion*; *Jeyes' Conqueror*; *Edwards' Invincible*; *Champion of the World*; and *Late Wrinkled Green*, are later and inferior forms of this. It is of a strong and robust habit of growth, 6 to 7 feet high, and with a branching stem and dark green blotched foliage. The pods are from twelve to eighteen on each plant, mostly in pairs, and contain seven very large Peas, which are of a dull green colour, like those of the Green Marrows. The ripe seed is mixed white and olive. This is one of the best Peas in cultivation, being an abundant bearer, as early as the Early Green Marrow, and having dark-coloured pods and Peas similar to those of that variety. Sown February 23. First flower opened June 6. Was in full flower June 13. First slats appeared June 15. Fit for use June 29.

Omega (Laxton).—A cross between Veitch's Perfection and Ne Plus Ultra; plant, robust, erect growth; stem, 2 feet 6 inches high, branching; foliage, large, deep green. The pods are produced in pairs from twenty to twenty-four on each plant. They are long, nearly straight, rounded in form, and very closely filled, showing the form of the Peas through the pod, of a very deep grassy green colour, which is retained for a long time; they contain about eight very large Peas, which are of a deep green colour, like Ne Plus Ultra, and of excellent quality. Ripe seed large, deep green, compressed, and wrinkled. Sown February 23. First flower opened June 9. Was in full bloom June 13. First slats appeared June 16. Fit for use June 30. A very excellent, handsome, and prolific Pea. Very distinct from all others. Keeps long in condition, after being fit for use, and stands the dry weather well; would be most appropriately named Dwarf Green Ne Plus Ultra. Received a first-class certificate.

Progress (Laxton).—A cross between Veitch's Perfection and Ne Plus Ultra. Resembling Omega in every other respect. It is a day or so earlier, and scarcely so large in pod.

General Wyndham (*Boyes's Masterpiece*).—The plant is of a robust habit, 6 to 7 feet high, and frequently branched. The foliage is dark green and blotched. The pods are either single or in pairs, and number from ten to fourteen on each plant. They contain eight very large Peas, which are of the deep dull green colour of the Early Green Marrow. The ripe seed is white and olive mixed. This is a valuable acquisition, and has evidently been raised from Ne Plus Ultra; but it is a much more robust grower, and produces much larger pods. The plant continues growing, blooming, and podding till very late in the season, and, when this is in the full vigour of growth, Ne Plus Ultra is ripening

off. Sown March 16. First flower opened June 13. Was in full flower June 17. First slats appeared June 19. Fit for use July 1. The Peas, when cooked, are of a fine bright green colour, and unlike those of any other variety.

Munsted Marrow.—Plant, very robust, with broader and shorter pods than Ne Plus Ultra, containing from six to eight very large deep green Peas; ripe seed, very large, deep green. Distinct in character. Comes into use a few days later than Ne Plus Ultra, of which it is a broader and shorter-podded form.

Sturdy (Laxton).—A cross between Veitch's Perfection and Ne Plus Ultra; plant, extremely robust and strong-growing; stem, 3 feet, branching very much, and flowering successively; foliage, large, deep green, slightly blotched. The pods are produced in pairs, from twenty to twenty-four on a plant. They are long, nearly straight, resembling Omega, but broader than that variety, of a beautiful deep dark green colour; they contain from six to eight large Peas, which are of a fine dark green colour, like Ne Plus Ultra. Ripe seed, very large, deep green, compressed and wrinkled. Quality excellent. Sown February 23. First flower opened June 13. Was in full flower June 19. First slats appeared June 21. Fit for use July 9. This is the latest Pea by several days of any in cultivation, and, by its habit of growing and flowering successively, a continuous supply of Peas fit for use is maintained for a week or ten days later still.

Dwarf Green Wrinkled Marrow (Veitch).—Plant, very robust, much branched; height, about $2\frac{1}{2}$ feet; foliage, large, broad, bright green, glabrous, or destitute of the usual glaucous hue, being similar in this respect to Danecroft Rival; pods, large, broad, pale shining green, but rather rough. They contain from seven to eight large pale green peas, which are very sweet and of good quality. Ripe seed, large, white, wrinkled. Sown March 21. Fit for use June 29. This is a perfectly distinct pea. It appears, however, to be somewhat tender, as, although the plant grew well and flowered abundantly, but very few of the pods filled out, the produce being exceedingly small.

Division VII.—Wrinkled Blue Marrows.

Ripe seed, blue and wrinkled. Foliage, dark green and much blotched.

Laxton's No. 1.—A cross between Dillistone's Early and Little Gem. This resembles Alpha in the characters and general appearance of the plant, but having straight pods, the same as Pioneer (white seed). Ripe seed, same as Alpha, small, light blue, wrinkled. Sown February 23. First flower opened May 10. Full flower May 22. First slats appeared May 25. Fit for use June 12. The earliest blue Wrinkled Marrow, coming into use the same time as Dillistone's Early.

Alpha (Laxton).—Habit and general appearance of plant like the Frame class or Sangster's No. 1; plant, rather straggling, weak, and somewhat tender, from 3 to $3\frac{1}{2}$ feet high; stem, simple, with light or pale green foliage. The pods are produced singly, from seven to nine on a plant. They are long, rounded in form, narrow, much curved and pointed, of a pale green colour like Sangster's. They contain from seven to nine good-sized peas in each, of a fine colour, and most excellent quality. Ripe seed, small, light blue, much wrinkled. Sown February 23. First flower opened May 12. Was in full flower May 23. First slats appeared May 26. Fit for use June 14. A very early and excellent wrinkled Marrow Pea, only two days later than Sangster's No. 1.

Fertility (Laxton).—A cross between Prolific Long-pod and Little Gem. This is scarcely distinct from Alpha, only having the pods a little more curved and the dried seed a little more green. It flowered, slatted, and came into use at the same time.

Little Gem (McLean's).—Plant, very dwarf, from 12 to 18 inches in height, but of robust and vigorous growth. Stem branching; foliage, dark green. The pods are produced in pairs, from seven to eight on a stem. They are of fair size, rather broad, nearly straight, very full, and contain from six to seven fair-sized Peas of fine colour and excellent flavour. Ripe seed, bluish-white, wrinkled. Sown February 23. First flower opened May 16. Was in full bloom May 25. First slats appeared May 28. Fit for use June 16. This is, indeed, a little gem amongst Peas, very valuable for forcing or growing in pots, from its extremely dwarf and prolific habit and its earliness, coming into use four days later than Sangster's No. 1.

Laxton's Gem (Laxton).—Plant, robust, branching; height, about 18 inches; pods, produced in pairs, from eight to ten on a stem, from 3 to $3\frac{1}{2}$ inches long, and a good deal curved and pointed, well filled, containing from eight to nine good-sized peas of very excellent quality. Ripe seed, green, wrinkled. This was selected as an improvement on Little Gem, having larger pods, and being more prolific than that variety. Sown March 21. Fit for use June 23. Awarded a first-class certificate.

Early Emerald.—Plant, from 2 to $2\frac{1}{2}$ feet high. This closely resembles Little Gem. It may be termed a somewhat taller and stronger form of that variety. It comes into use a day or two later. The dried seed is small, green and white, wrinkled.

Multum in parvo (Nutting).—Plant, robust, with large foliage, resembling Little Gem, but very distinct in the character of the pods. These are produced generally singly, and have very short peduncles. They are, generally, rather short and very broad, but well filled, containing from 5 to 6 large Peas, of excellent quality. Ripe seed, large, mixed blue and white, wrinkled. Sown February 23. First flower opened May 21. Was in full flower May 27. First slats appeared May 29. Fit for use June 19.

Multum in parvo (Selected).—No improvement on the true Multum in parvo.

Carter's Premium Gem (Carter).—This was considered an improvement on Multum in parvo. Sown March 21. Fit for use June 23.

Stamford Marrow (Laxton).—A cross between Supreme and Little Gem; plant of somewhat slender growth; height, 5 feet; foliage, pale green, blotched. The pods, which are produced in pairs from fourteen to sixteen on a plant, are very long, rounded and full, rather narrow, but much curved and pointed, of a pale green colour, like Alpha. They contain from nine to eleven medium-sized Peas, of a light green colour, very closely pressed, and excellent flavour. Ripe seed, pale green or blue, wrinkled. Sown February 23. First flower opened May 21. Was in full flower May 28. First slats appeared June 2. Fit for use June 17.

Advancer (McLean).—The plant is a free grower, of robust habit, and about 2 feet high, with dark green and blotched foliage. The stem is rather succulent and sometimes branching, producing from twelve to eighteen pods, which are generally in pairs, and contain eight very large peas, which are closely compressed. The ripe seed is green and wrinkled. This is one of the most valuable acquisitions that has been obtained of late years. It is, in fact, a green wrinkled marrow, as early as Early Emperor. It is remarkably productive, the pods fill well. When cooked, the peas are most delicious. It was raised by Dr. McLean, of Colchester. Sown February 23. First flower opened May 25. Was in full flower May 30. First slats appeared June 3. Fit for use June 21.

Universal (Laxton).—A cross between Little Gem and Laxton's Prolific. This resembles Little Gem in every respect, but with much longer, more curved, and narrower pods. The pods contain from seven to eight Peas, and, in some cases, nine, of fair size and excellent quality; ripe seed, blue, wrinkled, and flattened. Sown February 23. First flower opened May 24. Was in full flower May 28. First slats appeared June 2. Fit for use June 21, five days later than Little Gem.

Popular (Laxton).—Plant of rather slender growth, 6 to 7 feet high. The pods, which are produced in pairs from twelve to fourteen on each plant, are long, narrow, very tightly filled and compressed, like Fairbeard's Nonpareil, much curved and pointed, of a light green colour. They contain from six to eight large Peas in each, of excellent quality. Ripe seed, pale green or blue, wrinkled. Sown February 23. First flower opened May 24. Was in full flower May 27. First slats appeared May 30. Fit for use June 21. An excellent Pea for a general crop.

Epicurean (McLean).—Plant, robust, of full growth; height, 3 feet, having the habit of Nutting's No. 1, but inferior to that variety. The pods are borne in pairs, from ten to twelve on each stem. They are rather small, not very well filled, containing from six to eight Peas. Excellent quality. Ripe seed, white and green, wrinkled. Sown February 23. First flower opened May 27. Was in full flower June 2. First slats appeared June 5. Fit for use June 21.

Climax (*Fairhead's Excelsior*; *Napoleon*; *The Claimant*; *Lucking's Queen of the Marrows*).—The plant is of strong and robust health, 3 feet to 3½ feet high, unbranched. Foliage, rather light green and blotched. The pods, which are from thirteen to nineteen on a plant, generally in pairs, fill very badly, rarely containing more than four to six fully-developed Peas, the others being abortive. Ripe seed, green and wrinkled. This produces a great many pods, but they are badly filled. When first introduced, it was considered useful on account of its earliness; but now it is not worth growing.

Champion of England.—The plant is of a strong and luxuriant habit of growth, with a stem from 6 to 7 feet high, which is generally simple, but occasionally branched, and having light green foliage, which is scarcely blotched. The pods are from twelve to eighteen on a plant, and are generally single, but frequently in pairs, and contain seven to nine very large Peas closely compressed. Ripe seed, pale green and wrinkled. This valuable Pea is now too well known to require any commendatory remarks. This and Fairbeard's Surprise originated in the same pod, the latter being a round and the Champion of England a wrinkled-seeded variety. When sown, both varieties preserved their distinctive characters. Sown February 23. First flower opened May 29. Was in full flower June 9. First slats appeared June 21. Fit for use June 25.

Fairbeard's Fortyfold.—A selection of Champion of England, having large scimitar-shaped pods. Comes into use at the same time.

Culverwell's Early Wrinkled Marrow.—A fine form of Champion of England, with large broad pods and large Peas. Ripe seed, large, bright green.

Huntingdonian.—A large-podded and very excellent form of Champion of England.

Laxton's Quality.—Plant resembling Champion of England in growth, but with larger foliage of a much paler green and fully more robust. The flower is also large and handsome. The pods, which are produced in pairs, from fourteen to sixteen on a plant, are very large, rounded in form, much curved and pointed, of a light or pale green colour, they contain from seven to eight very large Peas of a light green colour, and of excellent flavour. Ripe seed, pale green and white, wrinkled. Sown February 23. First flowers opened May 21. Was in full flower May 27. First slats appeared May 30. Fit for use June 24.

Laxton's Quantity.—This, which originally was a round white-seeded variety, proved in the trial to be now but a form of Laxton's Quality with straighter pods.

Lord Palmerston.—In the way of Veitch's Perfection, with broader pods, but not quite so long, and somewhat paler in colour, very uniform. Comes into use with Hair's Dwarf Mammoth.

Knight's Tall Green Marrow (*Cullingford's Champion*).—Sown February 23. First flower opened May 29. Was in full flower June 5. First slats appeared June 12. Fit for use June 25.

Yorkshire Hero.—Plant, moderately robust; height, 3 feet, stem, simple, producing from twelve to fourteen pods on each, in pairs. The pods are short, broad, nearly straight, of a light green colour, and do

not fill well. They contain only from four to six fair-sized Peas. Ripe seed, light green, wrinkled. Sown February 23. First flower opened May 27. Was in full flower June 5. First slats appeared June 8. Fit for use June 25. This very much resembles McLean's Prolific.

Princess of Wales.—In habit and general appearance this very closely resembles Advancer. It might, indeed, be termed a good selected late stock of that variety. The ripe seed is lighter in colour than that of Advancer. Sown February 23. First flower opened May 30. Was in full flower June 8. First slats appeared June 12. Fit for use June 27, six days later than Advancer.

Conquest.—Plant of slender growth; height, 5 to 6 feet. The pods are borne in pairs from twenty-two to twenty-four on each plant; they are in appearance like the Early Emperor, small and narrow, containing from five to six small Peas in each, parti-coloured, light and dark green, of poor quality. Ripe seed, small, dull green, wrinkled. Sown February 23. First flower opened June 3. Was in full flower June 9. First slats appeared June 19. Fit for use June 27. A worthless and undesirable Pea.

G. F. Wilson (Carter).—Plant, robust, having the same appearance as Veitch's Perfection; height, 4 feet. The pods are produced in pairs, from ten to fourteen on a plant. They are very large, of a light green colour, and contain from seven to eight very large peas in each, which are of a fine green colour. Ripe seed, smaller than Veitch's Perfection, light green, wrinkled. Sown February 23. First flower opened May 29. Was in full flower June 4. First slats appeared June 7. Fit for use June 27. This is an early form of Veitch's Perfection, coming into use seven days before that variety. Received a first-class certificate.

Culverwell's Prolific Marrow (*Veitch's Tall Green Wrinkled Marrow*).—Resembling some of the forms of Tall Green Mammoth, of strong and robust growth; pods, short, straight, pale green, containing from five to six exceedingly large peas of excellent quality. Ripe seed, very large, bright green, wrinkled, very distinct in appearance. Sown February 23. First flower opened June 3. Was in full flower June 12. First slats appeared June 16. Fit for use July 1.

Tall Green Mammoth (*Green Tall Square Mammoth*; *Competitor*; *Epps' Monarch*).—The plant is a strong and vigorous grower, with a thick succulent stem, 6 to 8 feet high, and branched; foliage, dark green, and blotched. The pods are produced in pairs, and are from twelve to sixteen on a plant. Ripe seed, large, green, and wrinkled. Sown February 23. First flower opened June 3. Was in full flower June 15. First slats appeared June 19. Fit for use July 1. Thorpe-Parrow Early Marrow is a few days earlier, and with smaller and more pointed pods.

General Havelock.—A small-podded worthless form of the same.

Veitch's Perfection.—The plant is very robust in its habit, and produces a succulent stem, 3 feet high; foliage, dark green, and only slightly blotched. The pods are generally in pairs, of a large size, and from ten to fourteen on a plant. They contain from seven to eight very large Peas, which are closely compressed. The ripe seed is large, green, and wrinkled. This is an improved form of Hair's Dwarf Mammoth, than which it produces much larger pods, and comes into use about six or eight days later. It is decidedly the finest pea of its class, and one deserving of general cultivation. During the past season it suffered like many other varieties from the unusually cold wet weather, and dropped many of its blooms; but in the previous summer it set every bloom, and matured a profusion of its large well-filled pods. Sown February 23. First flower opened June 2. Was in full flower June 9. First slats appeared June 15. Fit for use July 4.

Mammoth Dwarf Marrow.—This is of the same type as Veitch's Perfection, but with rather smaller and more curved pods, of deeper green, and a day or two later.

Connoisseur (Laxton).—A cross between Ne Plus Ultra and Evergreen; plant of somewhat straggling growth; height, 6 feet; foliage, dark green. Stem, branching, producing from twenty to twenty-five pods in pairs. The pods are long, nearly straight, well filled, of a deep green colour, like Ne Plus Ultra. They contain from six to seven Peas each, which are parti-coloured, light and dark green, of very excellent quality. The ripe seed is small, very deep green, wrinkled. Sown February 23. First flower opened June 14. Was in full flower June 16. First slats appeared June 19. Fit for use July 7.

[The above article consists of three reports from the Royal Horticultural Society's Journal. These reports were prepared by, or under the direction of, the Pomological director and other officers of the society, from trials at Chiswick, extending over a series of years. We have combined and reprinted them, believing they will be useful to our readers for reference.—Ed.]

THE SEASONS.

If this white benediction of the snow
Fell not from Heaven upon our frozen fields,
Thy summer festival would hardly know
What wealth June ripeneth or proud autumn yields.
If never sorrow should come near thy heart
Nor any coldness dim the light of love,
Thou could'st not know thy nature's better part,
Or look for hope's best harvest from above.
Unbroken sunshine and perpetual heat
Make deserts only. Clouds that bring no rain
Shelter no gardens; and thine eyes, my sweet,
Must know what tears are, fond eyes to remain.

—Galaxy.

WORK FOR THE WEEK.

PRIVATE GARDENS.

Greenhouse Plants.—Remove some of the most backward *Cinerarias* to a north house, so as to preserve their lateness; water those that are in bloom freely, and occasionally with manure-water; keep them free from insects by fumigation. Chinese *Primulas* required for seeding should not be burdened too much; therefore reduce the quantity of flowers on each plant to one or two trusses, according to the strength of the plants. Remove into a corner of some pit the finest *Cyclamens* for seeding purposes; a dozen or so of flowers are sufficient on each plant, and there is no necessity for artificial assistance in fertilisation unless new colours are aimed at. Keep herbaceous *Calceolarias* growing gently, by supplying them liberally with water and keeping them in a light and airy house and near the glass. Re-pot such show and fancy *Pelargoniums* as require it, and, if possible, place them on stages quite close to the glass in houses abundantly ventilated; if a little artificial heat be given at the same time, a beneficial influence will soon be manifest in green healthy foliage and the firm stubby growth which are so productive of abundance of flowers. Violets that were bloomed in pots during the winter may now be transferred to a warm border. Give a little water to such Japanese Lilies as are beginning to grow. Hyacinths and Tulips should be kept as cool as possible, and in light houses. *Lachenalias* are now blooming pretty freely; keep them near the glass, and treat them liberally. Re-pot young *Fuchsias*, pinch the points of the branches at the fourth or fifth joint, and keep the plants in the warmest part of the house. Some of the old plants may be shaken out of their present pots and re-potted in others, according to size, in good open compost. In pruning the old plants, be rather sparing until they begin to grow. *Statice*s should be re-potted and kept in the warmest part of the greenhouse; the old plants may be shaken out of last year's pots and re-potted in smaller ones, for once growth begins in *Statice*s they must never suffer for want of pot-room. Save all seeds of *Solanum Capsicastrum*; cut down the old plants, and use the young shoots for cuttings. Re-pot, and remove for the same purpose the suckers of *Calla æthiopica*. Cut off the ends of the branches, and thin plants of *Veronica Andersoni*; then start them into growth. *Salvias* in pots, and rested during the winter, if now pruned, re-potted, and kept in moderate heat, become fine flowering plants in a short time. *Kalosanthes coccinea* should be re-potted in a compost of good loam and some thoroughly decayed manure. Cut back *Bouvardias* that have done flowering, and use the young shoots for propagating. Cut back, re-pot, and start into growth some plants of the Lemon-scented *Verbena*. Turn out into frames young *Chrysanthemums*, and see that none suffer for want of potting. Re-pot and stake choice *Petunias*, and sow some seeds in light soil in gentle heat, for conservatory blooming; the surplus may be economised for bedding purposes. Train Tree *Mignonette*, and admit plenty of air to dwarf-growing plants in pots. *Mimulus*es of the finer varieties, as well as Musk, may be potted in two parts loam and one of decayed manure, with some sand; they soon grow and form nice flowering plants. Wire baskets containing the latter, and also others planted with *Saxifraga sarmentosa* may now be made up either for the window or for suspending from the roof of the conservatory. Some Globe *Amaranths* may now be sown in moderate heat, and pricked off when the young plants appear. Balsams, Cockscombs, and other *Celosias*, *Cinerarias* for autumn flowering, *Schizanthuses*, &c., may be treated in the same way. Train *Tropæolum*s on their trellises, and give them a little manure-water once a week.

Fern-house.—Any potting that remains to be done here should be attended to at once. Many of the commoner kinds reproduce themselves freely; therefore, keep a quantity of these in small pots; they are useful for intermixing with large plants, the appearance of which is much improved by an admixture of small ones; and, if the latter are allowed to get somewhat pot-bound, their fronds will last in a cut state much better than those from plants more freely grown, and the better plants are saved from mutilation. All ought to be carefully picked over, removing such fronds or portions of them as are naturally decaying, yet do not cut out much that has life in it, as this has a tendency to weaken the plants. As the days lengthen, raise the temperature a little. Potting should now be proceeded with, as it is best to shift Ferns before they begin to grow; otherwise, they receive a check. Over-potting should be avoided, but, where good specimens are required, they should be shifted as they need it, and if for grouping amongst other plants, they should be grown in comparatively small pots. Brown Scale is the greatest enemy of the Fern-house, and, with the approach of warm weather, this pest will begin to increase apace if not checked. Every means should therefore be used to keep it down, as it soon renders the plants unsightly. As soon as growth commences, shade slightly during sunny weather,

and allow more moisture in the atmosphere as well as at the roots. Give air on all mild days, otherwise the fronds push weakly, a condition that should be avoided, as leaves of that kind never maintain a healthy appearance so long as is desirable. If thrips makes its appearance, fumigate frequently yet not too strongly.

Stoves.—Gradually increase atmospheric humidity and temperature in these structures, though very sparingly, and apply water rather more liberally to the roots of the plants. Almost all stove plants will now require re-potting or top-dressing, and insects, if any, must be destroyed; for, should they be spared till next month, they will reward such kindness by committing unlimited mischief. Plants of all kinds should, therefore, be thoroughly cleaned before they are re-potted. In the evening, place over some boiler "at work" or introduce into some warm house or pit, some soil, mixed and ready for potting purposes, for no stove plant should be shifted into cold soil. Shift Palms, using for the purpose a compost consisting of fibrous peat two parts, turfy loam one part, and some sand and finely broken crocks, an open compost, and plenty of water being requisite for such plants. Shake out plants of *Impatiens* and re-pot them in a mixture of loam, leaf-mould, well-decomposed manure, and some silver-sand. Give *Gardenias* a compost of loam and peat in equal proportions, mixed with sand; the same compost, with a little more loam mixed with it, will also suit *Brownias*. *Dalechampsias* should have leaf-mould, loam, and peat, in about equal proportions; *Stephanotis*, fibrous loam, peat, and well-decayed manure; *Sanchezias* and *Rondeletias*, peat, loam, a little leaf-mould, and sand; and *Lagerstroemias*, peat and loam. Indeed, most hard-wooded plants grow freely in good peat and loam, with some silver-sand added; and but few of them will object to the addition of a little leaf-mould. Gross-growing and soft-wooded plants, however, such as *Musas*, *Crinums*, *Eranthemums*, *Torenia*s, *Puyas*, *Pentas carnea*, *Gesneras*, *Lasiandras*, *Coccocypselums*, *Curcumas*, &c., are very fond of some thoroughly decayed manure mixed in the soil in which they are potted; leaf-mould, Mushroom-dung, spent hot-bed manure, &c., may be so used. *Anthuriums*, *Marantas*, tropical Palms, and many other stove-plants, should now enjoy a brisk and moist temperature. Pitcher plants and prunings may be economised for cuttings, that strike in any open material. *Nepenthes* should be re-potted in loose material, such as Sphagnum and very fibrous peat. *Dracænas* and *Dieffenbachias* may be propagated from pieces of the roots and stems, inserted in Cocoa-nut fibre, or similar material, in a brisk heat. Plants of *Bonapartea juncea* raised from seed may now be potted off singly into small pots. Take *Aralias* that have been struck from pieces of the root, and that are now pushing a few leaves, out of their propagating pans, and pot them separately. Prick off *Gloxinias* raised from seed into pans, or pot them singly into thumb-pots.

Indoor Fruit and Forcing Department.—Increase the day and night temperature of Pine-pits, in accordance with the weather, and give a little extra moisture to the roots, especially those of plants swelling fruit; but such as have nearly finished swelling should be kept moderately dry. Shift into fruiting pots all plants requiring that attention, and take off and pot suckers as they become ready. Do not starve young growing plants; for, if once checked, they are almost sure to produce small and premature fruit. Syringe with tepid water the surface of the beds and about the necks of growing plants, especially on fine days. As regards Vines, thin and stop the shoots, thin the berries, and keep up a steady moist temperature. Thin young Peaches where too thick; but do not make the final thinning until after the stoning period is over, and until that time maintain a steady and moderately low temperature. Regulate and thin the young shoots, and syringe morning and afternoon with tepid water on fine days, and once every day, regardless of the weather. If a little top air can be left on at night, and artificial heat given to maintain the requisite temperature, it will be of material importance to the crop. For Cherries, a temperature of 50° or 55°, will be sufficient until the fruit has stoned; afterwards the heat may be increased 10° by sun-heat, and, when the fruit is colouring, a night temperature of 60° and a day one of 75° or 80°, with sun-heat, will not be too much for them. An airy house and a position near the glass is of the utmost importance in Cherry forcing, and a high temperature either by night or day before the fruit has stoned is ruinous. Give manure-water, occasionally, to Fig-trees swelling their fruit, and syringe them freely until they begin to ripen. Pot Figs are commonly used for the earliest crop, and, where houses are not specially devoted to their culture, they may be successfully ripened in the Pine-stove or early Vinery. Stop the young shoots at the third or fourth joint, and remove all root suckers, unless a few are wanted next winter for fresh plants. The earliest Strawberries will now be ripe, or ripening, therefore they are best kept moderately dry and airy. Introduce plants of them for succession into Peach-houses or Vinery shelves, or into houses built purposely for them. For Cucumbers, keep up a bottom-heat of 75°, and an atmospheric.

one a few degrees lower; but, in the event of bright weather, an extra 5° would be rather beneficial to them than otherwise. If the heat from fermenting material be wanting, apply fresh linings or mix fresh dung with the old fermenting material. Sow a good successional crop of Cucumbers and Melons. Kidney Beans should be sown in succession fortnightly, or according to the demand; a Cucumber-house, Pine-stove, or early Vinery, suits this crop perfectly, and the plants must be freely syringed, to keep down red spider. Sow a few Tomatoes at once in a moderate hot-bed, or propagate by cuttings from old plants saved in pots during the winter; plants from these cuttings fruit earlier than from seedlings. Dust some sulphur over the foliage of Potatoes grown in frames, to keep down Fungi, &c.; apply water between the drills, but keep the necks of the plants dry. Rhubarb will soon be obtained abundantly from the open air, *i.e.*, if a forkful or two of litter be placed over the crowns; but a few roots for succession may still be taken into the Mushroom-house. Keep up a constant succession of forced Asparagus, either by placing roots in moderately-heated frames, or by filling trenches between the beds with fermenting material. Start a few more Seakale roots. A temperature of 60° and a humid atmosphere should be maintained in the Mushroom-house. Protect Lettuces in frames from snow and wet, and plant some out as convenience and weather may permit; sow some seeds for succession. Sow a few Capsicums in boxes, and pot them off singly, or prick them off when they are fit to handle. Sow some Celery seeds in a gentle heat. Sow some New Zealand Spinach in a brisk temperature, for summer and early autumn use. Thin Carrots in frames; keep them dry, and shelter them from snow or rain, but expose them freely in favourable weather. Sow some Turnips, Radishes, and Onions, in gently-heated frames, to precede those sown out-of-doors.

Hardy Fruit Trees.—Finish the pruning and nailing of fruit trees on walls as expeditiously as possible, and give the trees a thorough washing with the garden engine. Some kind of protection must be afforded to Apricots and Peaches, so as to preserve their blooms from frost. Fruit trees and bushes may yet be planted, but the sooner the operation is finished now the better. Cuttings of Gooseberries may still be made, and inserted in nursery lines a foot apart, and from 4 to 6 inches asunder in the row; cuttings put in in autumn are, however, preferable to those inserted in spring. The cuttings should be 10 inches long, and divested of all buds except three or four at the top. No buds should be buried in the soil, nor be allowed to exist on the 3 inches of stem just above the ground. Scions for grafting should be taken off, if not already done, and "heeled in" until wanted for use. Make fresh plantations of Strawberries if necessary; remove all runners from old ones; fork over the soil between the rows, and incorporate with it some well-decayed manure at the same time. If a dressing of rough litter be applied between the rows after the ground has been forked over, it will serve as a mulching, and the rains will wash down nutriment from it to the roots, while the surface will form a clean resting-place for the forthcoming crop.

Kitchen Garden.—Make plantations of Jerusalem Artichokes in lines from 2 to 3 feet apart, in any odd corner of the garden. Plant Horseradish sets 15 inches deep, in deeply-trenched ground, in rows 18 inches asunder. Plant the main crop of Potatoes. Autumn-sown Angelica should now be transplanted in rows 2 feet apart, in rather moist soil. Mint may be divided and transplanted alongside of the Angelica, in lines 15 inches apart. Seakale roots may be transplanted for next year's crop, and some seeds of it sown thickly in beds. Divide the roots of such plants as Hyssop, Chamomile, Pennyroyal, Sage, Savory, and Rue, and transplant them into fresh beds. Sow some Marrow Peas; a good plan is to plant four rows of Potatoes, then a row of Peas, and so on; this gives the Pea crop more light than it otherwise would have. Sow a full crop of Beans, and draw some earth to those that are above ground. Sow some Leeks for transplanting; also some Parsnips in lines 20 inches apart, in deeply-trenched ground. Sow likewise some Cos Lettuces on a warm border, and plant out those that have been wintered in frames. Sow some round-leaved Spinach between rows of dwarf Peas or elsewhere; also early Horn Carrots at once, if the ground is in good order. Sow a crop of Onions as soon as the ground is in good condition for its reception, and, if Parsley has not been already sown, some may now be put in. Sow also some Asparagus seeds in drills 18 inches apart, but do not transplant last year's seedlings till April. Gradually remove the protecting material from the necks of Globe Artichokes. Sow some Brussels Sprouts and other members of the Cabbage tribe for autumn use. Of Rocambole, Garlic, Chives, and Shallots, transplant cloves or offsets at once.

WOMAN is like Ivy—the more you are ruined the closer she clings to you. An old bachelor adds: "Ivy is like woman—the closer it clings to you the more you are ruined."

SOCIETIES, EXHIBITIONS, &c.

THE ROYAL HORTICULTURAL SOCIETY AND GUINEA SUBSCRIPTIONS.

Will you kindly allow me a small space to answer objections raised to the guinea subscription plan. At the Wednesday meeting, the other day, I was placed near some good specimens of their respective branches of the profession, two well-known nurserymen and two first-class gardeners. One of the former suggested that I was trusting too much to gardener subscribers; as one of the gardeners spoke out well for his class I left them to settle the matter between them, but afterwards had the objection raised more fully. Will you now allow me to answer it? I never contemplated the social position of the society being lowered, or that the renovated society should consist, in a very large part, of gardeners, though I believe that a considerable accession of these more working bees would greatly strengthen it. A head gardener, to keep his situation in a large place, must be a superior man, and it is only the best of these (such as those who work so actively on our committees) who would take enough interest in general horticulture to make them afford the guinea annual subscription. In very many cases their influence would make their employers join the society. Judging from the letters that come to me, the idea of the guinea fellowship has been most warmly taken up by people in as high social station as that of the present fellows, and they talk of influencing their friends (presumably of the same class) to join with them. I see the acting council has published, *in extenso*, in one of your contemporaries the society's accounts for the past year. Let anyone look through these, bearing in mind that much of the cost of Chiswick goes for furnishing South Kensington, and judge for himself whether a society with the guinea subscriptions of 5,000 fellows would not have far greater working power than the society in its present state has with the much larger income, of which the lion's share goes to keep up a square for the Kensingtonians.

GEORGE F. WILSON.

Heatherbank, Weybridge Heath.

THE LINNEAN SOCIETY.

AN article, which appeared in *Nature* about ten days ago, referring to what took place at this society's meeting, on the 5th instant, is stated by the *Globe* to have been somewhat one-sided. It relates to certain changes made in the bye-laws, which are unsatisfactory to many of the fellows. Into all these changes, it is unnecessary to enter, as several of them are of little importance. Their chief effects are to remove the disability of fellows of the society to hold any office of emolument in its service, and to transfer the appointment of paid officials from the hands of the fellows to those of the council; and to enable the council to pay for the editing of the "Journal and Transactions" of the society, which has hitherto been done by the honorary officers. Some objected to the last of these changes, others wished to retain the abnegation clause in its integrity; but all who opposed the action of the president were, not unnaturally, averse to allowing the appointment of their paid officials to be taken entirely out of their hands. That there is some reality in this grievance may be inferred from the fact that the present librarian, who has performed the duties of his office most satisfactorily for many years, was appointed by the society at large in opposition to the nominee of the council. But besides the possible inconvenience of the appointment of a paid official in such a manner as to render him responsible only to the council, the objectors to this course have another argument on their side. This transfer of the power of appointment is in direct contravention of the charter of the society, which definitely places all elections and appointment of the officers of the society in the hands of the fellows only. It is, of course, impossible for a bye-law to override the charter by which the society is incorporated, but the opposition feels that if the new bye-law is acted upon, the position of the society may be very seriously compromised. We hope that, at the approaching general meeting, the fellows may be able to arrive at a satisfactory solution of their difficulty.

OBITUARY.

THE current number of the *Belgique Horticole* contains a notice of the death, and a review of the life, of M. L. Jacob-Makoy, of Liège. Readers of horticultural journals are familiar with his name as that of one of the most successful cultivators of Camellias, Cape plants, hardy Rhododendrons, Roses, and Dahlias. So far back as 1845, the houses of M. Jacob-Makoy contained no fewer than 200 species of Palms.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE WHITE LILAC IN WINTER.

AFTER the sweet Violet—sold by millions of bunches—perhaps the most welcome plant in the flower-shops of Paris in winter and spring is the white Lilac. It has for a good many years been popular in Paris and other continental cities, and more recently has been frequently seen in Covent Garden, invariably imported from Paris. The production of this white Lilac has long been a source of interest to cultivators, on seeing snowy fragrant masses of it in the shops so early as October. Many persons have supposed it to be a white variety of Lilac, but this is not so; it is the common kind forced into bloom in the dark, and, though the blossoms are of as pure a white as most white flowers, they are simply blanched, just as the shoots of Seakale are blanched. At first, the white variety of the common Lilac would seem to be the most suitable for forcing in the above-named manner, but those who have tried it found it much less suitable. In the dark it does not make such a vigorous growth as the common Lilac, and, oddly enough, the flowers do not come of so pure a white. The French force the common Lilac in great quantities, for yielding these white blossoms, both in pots, and planted out in beds under glass. The plants intended to be forced are cut round with a spade in early autumn to induce them to form flower-buds more abundantly, and this also facilitates their removal in a compactly-rooted manner at a later period of the same year. They are at first, when taken up and placed in the house in which they are to be forced, kept somewhat cool, but soon the heat is increased till it reaches from 80° to nearly 100°, and abundance of moisture is supplied at the same time, both at the roots and over the tops; in the last case by syringing with tepid water. The chief point, however, is, that from the day the plants are placed under glass they are not allowed to receive a gleam of light, the glass being completely covered with *paillassons*, or woven straw mats, such as are much used on the Continent for covering frames, pits, and all sorts of garden structures in winter. Thus they get the Lilac to push freely, and gather its white blooms before the leaves show themselves much. The heat and moisture and complete darkness effect all that is desired. The Paris growers commence to cut the white Lilac at the end of October, and continue to do so till it comes in flower in the open ground. Up to the present time, the white Lilac blossoms have rarely been seen with us except when imported; but we are glad to say that a well-known and excellent plantsman, Mr. Howard, gardener at Bedford Hill, Balham, near London, has produced it this winter abundantly, and in a simple manner. In autumn, and at various periods throughout the past winter, he dug up some bushes of the common Lilac and placed them in a darkened stokehole-shed used for forcing Seakale, &c. This structure is heated by a hot-water pipe which passes through it, but not to so high a temperature as that which is used by the Paris growers. In fact, the conditions are such as gardeners commonly employ for forcing Seakale, and any roots which they desire to force and blanch. From this shed, in which the bushes have flowered abundantly through the winter, Mr. Howard has gathered quantities of pure white Lilac, with all its fragrance perfect. Thus, Mr. Howard has proved that the production of this charming addition to our winter forced flowers may be effected wherever Lilac bushes are grown in the shrubberies, and where Seakale, Mushrooms, or the like are forced in a shed. As the Lilac, in a free-flowering condition, is usually a goodly-sized shrub, more head-room will, of course, be required for it than for the other subjects named. One grower in Paris found that ventilation, even that afforded by a broken pane, caused the flowers to commence assuming their natural colour. Among the coloured varieties found to succeed treated in this way, the best were the Lilas de Marly and Charles X. The Persian Lilac tried in this way has not been found to suit.

THE TREE MEDICK (MEDICAGO ARBOREA).

At p. 148, you ask if any of your correspondents have noticed this plant at Brighton or elsewhere. I have known it as growing freely in most exposed situations at Weymouth for the last twenty years, in front of some of the villas. It is planted against the palings, and entwines its branches through the rails, forming, when cut with the knife or shears, a pretty close-growing evergreen hedge, generally covered with its bright orange flowers throughout the whole year. I may just say that I was at Weymouth the other day, and picked some flowers of the Medicagos there, and, as many persons are much interested about what grows well or best on exposed sea coasts, I will mention a few that I can say brave the most stormy locality. One locality I saw last week covered with sea spray as with a shower of rain. In this spot, upon a strong blue (Oxford) clay, I planted last year about 2,000 trees and shrubs, of as many kinds as I could, on purpose to try their sea-resisting properties. They were exposed to the N.E., E., and S.E. winds, and were close to the beach, up which the storms often hurl the dashing waves in wild fury, bathing everything in salt and water, and leaving every vestige of vegetation drenched with wet. In such a locality one would have thought all sorts of trees would have perished. I give below a list of some kinds that I found sea-proof, and this, too, after encountering one of the fiercest storms that has visited the Weymouth coast for several years. But it is not the winter storms that destroy the trees. April and May are the fatal months; just as the young growth begins, and the plants are full of sap, it is, at the sea-side as it is inland, the time when vegetation suffers most, when exposed to pinching frost and cold N.E. storms, the plant in full growth succumbs with more certainty at this period of the year, when the thermometer is at 6° to 8° below freezing, than it does in midwinter with the glass below zero. I will mention one plant that the slightest frost in spring destroys, whilst it will stand unharmed through the severest winter; this is the *Cupressus funebris*. Such is the effect of spring frost upon it, that it has been found almost impossible to keep it alive. But to return to the sea-coast and the plants I find do best upon it; these are mostly those kinds that have got thick, leathery, shining, or glaucous leaves, and those that are covered with cottony down. Amongst the first, I may instance the *Euonymus* tribe, as they, *par excellence*, hold the first place; no storm or sea-spray seems to injure them, however severe; I planted many hundreds of them in the bleak place I mentioned above, not one has suffered, but, on the contrary, they are shooting their young growths as if it were mid-summer. Then follow *Pittosporum* Tobira, *Camellia*, *Escallonia*, *Daphne*, *Mahonia*, *Griselinia* (as hardy as the *Euonymus*), *Olea ilicifolia*, *Phillyrea*, *Evergreen* Privet, *New Zealand* Flax, *Bay*, *Ivy*, *Rhododendron*, *Hydrangea*, *Veronica*, *Laurustinus*, *Arbutus*, *Ardisia*, *Brooms*, *Cotoneaster*, *Eleagnus*, *Eugenia*, *Eurybia*, *Garrya*, *Double and Single Furze*, *Evergreen Oak*, *Fulham Oak*, and the evergreen sort called *Austriaca sempervirens* (this is a grand sea-side tree), *Photinia dentata*, *Pyracantha*, *Cock's-Spur Thorn*, *Raphiolepis*, *Skimmia*, *Pyrus japonicus*, *Sambucus*, *Ribes sanguineum*. Amongst *Coniferae* but few will brave such a locality as I have mentioned, and of this tribe the best is *Araucaria imbricata*, the *Silver Fir*, and *Picea Nordmanniana*; all others of the tribe perished in May, even the celebrated seaside Pine, *P. austriaca*, failed. Amongst woolly-leaved plants, I may set at their head *Cineraria maritima*, *Stocks*, *Centaureas*, *Gnaphaliums*, *Cerastiums*, *Buddleia*, *Salvias*, *Santolinas*, *Lavender*, and *Rosemary*. Of glaucous-leaved sorts, pre-eminent is *Sea Purslane*, *Silene montana*, *Horned Poppy*, *Eryngium maritimum*, and *Frankenia fruticosa*. Amongst many sorts of Grasses, I may mention *Arundo Donax* and *conspicua*, *Pampas Grass*, and *Dactylis glomerata variegata*, and I must not forget *Coronilla glauca*, *C. Emerus* and *valentina*; and of trees, *Scotch and Canadian Elms*, *Turkey Oak*, *Beech*, and *Horse-Chestnuts*. The above are what I find to resist the best in the most exposed places; but, on getting a little away from the immediate beach, a greater variety succeeds. I have just finished planting some thousands of all sorts, at Weymouth, and hope to be able to give you an account of their behaviour next year. JOHN SCOTT.

What is the best Stove for a small Conservatory?—I have a conservatory 18 feet by 12 feet, with a span roof 15 feet to the top. It used to be heated by an ordinary portable stove, with a descending flue, which never acted, so the stove was taken away, a large copper pipe still remaining available for a flue. We have tried Joyce's stove, and several gas stoves, not connecting them with the piping above-named, but the smell is very bad, and we cannot sit in the adjoining drawing-room. I ought to say that the conservatory is too far from the other hothouses to be connected with them. Can any of your correspondents recommend any stove which we could connect with the copper piping, which would contain fuel enough to last a winter night and just keep the frost out?—R. J. B.

NOTES OF THE WEEK.

— WE are informed, by M. Boissier, that the handsome purple-flowered *Geranium*, recently figured and described in the *Gartenflora* under the name of *G. Backhousianum*, is, in reality, *G. armenum*, described at p. 878 of M. Boissier's "Flora Orientalis." This plant, in its wild state, is only found in Armenia, whence, some years since, M. Boissier received seeds of it, which first germinated in the Botanic Garden at Geneva.

— THE sap of the *Rhododendron* and *Laurel* are strong poisons, and, when cattle partake of the leaves, death is often the result. A Scotch ox died last week from eating the dead leaves that had been thrown into a field some days previously.

— ON Saturday evening, during some rejoicings at Wardour Castle, the seat of Lord Arundell, on the result of the Claimant's trial, a small cannon burst, and Mr. George Ford, the gardener, was struck by a fragment of the metal, and so much hurt that he died in the course of the evening. A boy was also killed on the spot.

— MR. PHILIP BARNES, long known to many frequenters of the Botanic Gardens in the Regent's Park, died the other day at the age of eighty-two. Thirty-four years ago he founded the Royal Botanic Society, and was the oldest fellow and father of the society.

— THE current number of the *Botanical Magazine* contains figures of the following plants:—*Odontoglossum Roezlii*, a handsome white-flowered Orchid from New Grenada; *Bauhinia natalensis*, a white-flowered Leguminous shrub, from Natal; *Arabis blepharophylla*, from California, a rosy-flowered species, now often seen in good collections of hardy plants; *Nunnezharia Geonomæformis*, a pretty dwarf Palm from Guatemala; and *Rhipsalis Houlletii*, a singular-looking plant belonging to the Opuntian section of Cactuses, and supposed to be a native of Brazil.

— M. JEAN SISLEY, of Lyons, has recently sent to the *Revue Horticole* an extract of a letter from his friend, Dr. Henon, who is at present in Japan, in which the latter states that he was much surprised to find, in the neighbourhood of Ikouno, several specimens of Bananas growing in the open air, which died down under the winter frosts, but made fresh growth in the following spring. These, he adds, were cultivated for ornament only. It would be interesting to know what species of Banana is thus alluded to, as we do not suppose the climate of Ikouno can be much milder than our own; and a hardier kind of Banana than any of those with which we are, as yet, acquainted, would be a material acquisition in our gardens and pleasure-grounds.

— IN the *British Medical Journal* for February 21, Dr. J. Dixon, of Whitehaven, publishes a case of a boy who exhibited severe symptoms of poisoning after eating Mistletoe berries. The patient was fourteen years of age, and was found lying in the street in a state of insensibility, within forty minutes of the time of eating the berries. The first impression was that he was in a state of alcoholic intoxication, but no trace of alcohol was found in the breath or subsequent vomit. An emetic of sulphate of zinc was administered, which brought off eight partly masticated berries. There were indications of considerable cerebral hyperæmia, which was appropriately treated, and the boy was well the next morning. He stated that soon after eating the berries he began to feel giddy, and from that time had no recollection of what transpired.

— ACCORDING to the *Bulletin Thérapeutique*, an attempt made by a Paris merchant to utilise the sewage of that city in the cultivation of labiate plants in the plain of Genevillers has been so successful, that at the present time three hectares of land ($7\frac{1}{2}$ acres) are devoted to the raising of Peppermint alone. The plant is said to grow with such vigour, that three collections are made in each year, whilst the essential oil obtained from it by distillation is asserted to be superior in delicacy of aroma and flavour to that imported from England. So satisfied are the directors of the Pharmacie Centrale with the results, that they express their readiness, should any pharmacien be sufficiently enterprising to extend the experiment to the neighbourhood of the manufactory at St. Denis, to undertake to use all the produce.

— WE have to record the death of Dr. Neil Arnott, an event which took place the other day at the advanced age of eighty-five. To horticulturists he was best known by his treatise on "Warming and Ventilation," and by the stoves which bear his name. For this and for other novel applications of science, to the preservation of public health, the jurors of one department of the Universal Exposition of Paris of 1855 awarded him a gold medal, to which the Emperor added the Cross of the Legion of Honour. As the inventor of the "Arnott stove," the "Arnott ventilator," and the water bed, for which many a sufferer owes him a debt of gratitude, it is not likely that his name will soon be forgotten; but it deserves to be recorded in his honour that he constantly refused to patent his invention, from the wide use of which he might have reaped, had he pleased, a handsome income. This, however, he declined to do; he

sought a higher reward than that which money could have given him; and, accordingly, what he sought he found before his decease.

— IN order that some idea may be formed as to the enormous extent of land required to grow trees for building and other purposes, in Europe alone, it may be stated that no less than 500,000,000 of acres are at this moment estimated to be in cultivation as woodlands, which is a very large per-centage on the whole area.

— THE coloured plate of the current number of the *Revue Horticole* represents the flowers of *Hydrangea acuminata*, a very hardy, vigorous-growing, and handsome species, from Japan. The umbel bears, on its outer margin, a single row of large sterile flowers, the petals of which are of a fine rose-colour, and are cut or scalloped on the anterior edge. The centre of the umbel contains a great number of very small fertile flowers, the colour of which is of a much deeper rose. This species, unlike some other *Hydrangeas*, thrives well in the full sunshine. It is offered for sale by MM. Thibaut and Keteleer, nurserymen, Sceaux, Paris.

— ONE of our correspondents in Paris writes to us (says the *Pall Mall Gazette*) that the most superb bouquets of artificial flowers are being prepared there for presentation at Chiselmhurst on the 16th inst. In most of them Violets predominate. One, which is exhibited in the Boulevard Haussman, is of great size, and is composed of Red Roses, in the centre of a circle of white flowers, and an outside one of blue. The whole is, at it were, powdered with golden bees, and some Laurel twigs artistically twined, form the following inscription:—"To Napoleon IV. on his birthday, the 16th of March." One immense bouquet of Violets has already been sent to Chiselmhurst. It measures 3 feet in height, and is fully $2\frac{1}{2}$ yards in circumference at the broadest part. It is composed of dark and light-coloured Violets, surrounded with leaves of the same flower, and around the centre is a circle of flowering Heather, emblematic of the Scottish descent of the Empress.

— THE last number of the *Gartenflora* contains a description and coloured plate of a very handsome species of Saxifrage, which, up to the present, seems to be very little known or appreciated by cultivators. This species, which is named *S. florulenta*, Moretti, is a native of Northern Italy, in the region of the Maritime Alps. It forms a dense and handsome rosette of lance-shaped, sharply-pointed, radical leaves, very closely crowded together, the entire rosette being roundish in outline, 4 inches or so across, and nearly 3 inches deep. From the centre of the rosette it sends up a very stout flower-stem about 10 inches high, which, at blooming-time, is covered, throughout its entire length, with a great profusion of rose-coloured flowers, arranged in a thyrsoid panicle. The plant, as figured in the *Gartenflora*, is one of the most effective species of Saxifrage we have seen, and is well worthy the attention of all lovers of hardy plants. We believe Mr. Maw was the first to introduce it into English gardens.

— IN the report of the directors of the Chiswick Gardens, it is stated that a trial of Grapes will forthwith be instituted there. Many new varieties of the Grape Vine, it is observed, have been introduced into our gardens within the last few years, and it has been thought desirable to devote a house to the growth of these, with a view to a closer observation of their peculiarities and merits. The small curvilinear Vinery in which the different sorts of White Muscats had been brought together some years since for a like object, which has been accomplished, has been set apart for this purpose. Such work as this, and the trials of vegetables and flowers which are every year made at Chiswick, well befit a society like the Royal Horticultural, which was founded for the advancement of horticulture. It is to be wished that circumstances permitted more of this kind of work to be taken in hand, and that the strife and bickerings which have of late been too notorious might be abandoned, and a united and unanimous effort made to put the affairs of the society on a more secure foundation.

— AT a recent sitting of the Institut Egyptien, Dr. Schweinfurth pointed out that many of the cultivated plants which are not known in the wild state in Lower Egypt are represented by identical or nearly allied spontaneous forms in the countries adjoining the Upper Nile. The common Luffa, or Washing-gourd (the fibrous skeleton of the fruit of which is sometimes sold in this country as a substitute for sponge), is wild in Central Africa, and only known as cultivated in Egypt. He finds the origin of the Vine of Egypt in a wild Abyssinian species. The Olive he seems inclined to refer back to the shores of the Red Sea; while the Sycomore Fig, Doum Palm, and Date all seem to him to belong, in a wild state, to the south. From the remarkable but well-known fact that the Lotus (*Nelumbium*) has disappeared from the whole Nilotic region within historic times, and that the Papyrus is not now found beyond 9° N. lat., he arrives at the conclusion that the climate of Egypt has lost the characteristic features which formerly united it with that of tropical Africa, and that the natural productions of the country have gradually become more northern.

THE FLOWER GARDEN.

TALL BELLFLOWERS.

By J. C. NIVEN, Botanic Gardens, Hull.

THE genus *Campanula*—with which, in its widely-distributed representative, the common Hairbell of our heaths and hedge-rows, and the Canterbury Bells of our gardens, we are all familiar—is one to which the gaiety of our herbaceous borders is, in no small degree, indebted. The result of the close and careful analysis of the natural order *Campanulaceæ*, made by De Candolle for publication in his “*Prodromus*,” led to a slight dislocation in the old typical genus of the order, by which sundry offshoots sprang into existence; and, while a large majority of species of *Campanula*, according to old authors, were retained as Bell-flowers, certain distinct forms were made sponsors for new genera on account of special structural peculiarities, into the details of which I need not here enter, but content myself by saying that these peculiarities are co-existent with a distinct general habit and contour. Foremost amongst these new genera stand *Platycodon* and *Adenophora*, to the former of which I wish now to direct attention. The title *Platycodon*, which is of Greek etymology, literally means broad-bell, and has been given to this genus, which embraces a small group, in which, although the base of the corolla is somewhat contracted, the limb expands broadly into widely-diverging segments. It has also a marked peculiarity in its unexpanded flower-buds, which are so much inflated as to justify the name by which it is known amongst Orientals, viz., the “balloon plant,” a name which, no doubt, will acquire general popularity.

Platycodon grandiflorum.

This was originally an introduction from Chinese Tartary, about the close of the last century, and was then supposed, as coming from the East, to be, if not tender, at least only half-hardy. Under the somewhat restricted mode of culture to which it was subjected as a pot-plant, it so rarely produced more than one flower on each stem, that there were some doubts as to whether it was justifiably referred to Jacquin's *Campanula grandiflora*, in which the flowers were described, from wild specimens, as usually occurring in terminal clusters. It was, however, found, on reference to the “*Herbarium*,” that occasionally the stems were unifloral, even amongst the native specimens. Possibly, in a wild state, as in cultivation, the number of flowers depended very much on the circumstances under which the plant was grown, and also the age of the plant from which the specimen was taken; as, in my experience, I have never known, except in a solitary instance, more than one flower produced in the first season of blooming. The same remark applies to many of our very best long-lived perennial plants; hence the frequent dissatisfaction expressed by over-sanguine cultivators, who forget that in proportion to the natural longevity of the plant is the time required to attain its full power of floral development. *Platycodon grandiflorum* is a thoroughly good herbaceous plant, perfectly hardy in light dry soils, but most impatient—as, indeed, is *P. autumnale*—of damp and undrained situations, where its

*Platycodon autumnale*.

thick fleshy roots are sure to decay—sometimes from below, upwards; but more generally from above, downwards, rotting off just at the neck. As the specific name would indicate, the flowers of *P. grandiflorum* are much larger than those of its closely-allied species *P. autumnale*, being as much as 2 to 3 inches across, of a deep blue colour, with a slightly slaty shade therein, reminding one a good deal of the old *Lisianthus Russelianus*, now so rarely met with in cultivation. They are produced in clusters at the summit of each of the branches, which proceed from the old root-stock, rising to a height of about 18 inches, and being very slender at the base. If neglected in the matter of supports in their early stage of growth, they are sure to fall to the ground, thus giving the plant, however beautiful its blossoms may be, an untidy appearance. This a little forethought will readily obviate; but, be it noted, if such a result occurs from early neglect, it is almost impossible to remedy it when the flowers are nearly developed, as branch after branch will break away, if made to assume the usually erect position, in the process of tying. When down, it will be better to leave them as they are, allowing the bloom to compensate, by its beauty, for any untidy appearance that the plant may present, merely taking the precaution to peg down the branches, else the sportive winds may whisk them round, and effect their total dislocation from the parent stock. Possibly the best position for such a plant would be overhanging a rock-ledge in a sunny corner of the rock-garden, where a somewhat negligent character of growth would be in keeping with its situation, and its flowers, produced on a level with the eye, would be shown to great advantage. Like most of the *Campanulas*, it has a tendency to sport in colour, and to revert from blue to white through various modifications. Equally pretty and acceptable, as a garden plant, is the white variety; though it is by no means so frequently met with as the blue type.

Platycodon autumnale.

This species comes from China and Japan, and I am not sure if those botanists who look upon it as nothing more than a slightly modified form of the Siberian plant, may not be correct; be that as it may, its general characteristics, as regards growth and habit, are, under cultivation, both distinct, and constant, and give it a much better defined specific character than that which many universally recognised species possess. Compared with *P. grandiflorum*, it is both taller and more robust in growth, attaining a height of 3 feet under favourable circumstances; its leaves are narrower, but more densely arranged than those of *P. grandiflorum*; and its flowers, though smaller in size, are produced in greater quantities and are pretty evenly distributed along the upper half of the stems—this arrangement is shown in the accompanying representation of the plant. From its taller stature, and, also, the fact that its young shoots are far more woody and vigorous in their growth than those of *P. grandiflorum*, its true position should be in the second or third rank of the herbaceous border. Besides a white variety, we find in this species, a tendency to become semi-double, by a sort of “hose in hose” re-duplication of the corolla, similar to what occurs in many of our *Campanulas*. This variation I have not noticed in the large-flowered species.

Cultural Remarks.

There are one or two specialities in the matter of cultivation that apply equally to both species. First, as regards removal; if a strong well-established plant is to be transplanted, let it be done in the month of May, when growth has commenced; the thick fleshy roots are sure to be, more or less, damaged in the process, and nature must be in an active state to repair such damage. If this be done during the winter, when the plant's energies are dormant, decay from the mutilated parts of the root upwards, is sure to take place, and the strong probability is that the entire root-stock will become affected. The spade must be looked upon as a decidedly warlike implement to use among these plants; one unlucky thrust through their brittle crowns and they, the plants, are gone for ever. Indeed, the less such an implement is used, in borders devoted to the culture of herbaceous plants, the better. In cutting down the stems in autumn, it is usual, with a view to neatness, to cut close to the crown. This, however, as Nature herself teaches

us, is not at all times good practice, and this especially applies to the *Platycodons*; if cut close, their hollow stems form conducting pipes to carry water into the very heart of the plant, and the result is decay from above downwards. The same caution is applicable to many other plants besides *Platycodons*. As regards propagation, the best mode is that of raising seedlings. Unfortunately, our climate is ill adapted to the maturation of seeds in general, and especially so with regard to *Platycodons*; they, however, seed freely on the Continent, and from that source a supply can readily be obtained. The young shoots, taken off when about 3 inches long, in spring, will strike if placed in a gentle bottom-heat, but not freely. I have seen it stated that the fleshy roots, cut into lengths and placed under similar treatment, will grow; but my experience only realised the development of buds at the upper end, accompanied by decay in place of root-development below, and the final result was failure. To those who possess strong vigorous plants of either species, I would say: Don't disturb them, even at the pressing wish of your best friend who may covet a portion thereof; rather get a packet of seed, and exercise all the patience you may happen to possess, and the result will be more satisfactory both to yourself and your friend than if your well-established plants had been mutilated in an attempt at division.

BEDDING CALCEOLARIAS.

THE following directions as to how these should be propagated may be of use to beginners. The *Calceolarias* bloom mostly in summer, and scarcely can a shoot be then found that does not contain an embryo flower-spike. Such shoots make bad cuttings; and, besides, they are then so soft and watery, that they do not strike well; and, although, we might like to propagate our next year's stock at that season, they would grow too much before winter, and would not only require transplanting, two months' extra attention, and pinching, but they would also occupy more frame-room during winter than later-struck cuttings would do. The proper time for propagating such *Calceolarias* is the end of September and October. For this purpose, prepare a cold wooden or turf frame on a dry basis, fill it to within 6 inches of the top with sandy loam, and over that spread some clean silver-sand. Then select nice stubby side-shoots, as firm as possible, pick out any flower-spikes that are visible, remove one or two of the base-leaves, cut horizontally below a joint with a sharp knife, and dibble them thickly, regularly, and firmly into the frames, giving them a sprinkling of water, through a fine rose, to settle the soil and to prevent the cuttings from flagging. Keep the frames close and shaded for a day or two; but afterwards remove the shading, and only use it again during the succeeding month to counteract the effects of bright sunshine. Such cuttings take a long time to root; but, if the atmosphere of the frame is kept dry, and the plants free from damp by dredgings of wood-ashes, dry dust, and old lime-rubbish, they will root satisfactorily during winter, and in spring will yield tops for additional cuttings; but, whether employed for cuttings or not, they are best pinched off. These frames require no further care beyond protection, by means of covering the sashes, in the event of frost, and banking up the sides, if of wood, with soil. Wooden boxes, seed-pans, or pots might also be used for striking *Calceolarias* in; in which case they might be wintered in any pit, greenhouse, or conservatory. Whether they are propagated in frames or boxes, they should be transplanted further apart than they previously were into other frames, filled with rich open soil, in which they will become fit for planting out by the middle of May, if the shoots have been attentively pinched when they required it. In autumn, too, it is a good plan to draw some earth around the necks of the old plants, so as to induce the emission of roots from that portion of their stems; and, at lifting time, in November, to separate every rooted branch, and plant them as independent plants in frames. They will yield abundance of cuttings in spring, but it is from a few old plants, lifted and saved in frames for the purpose, we get our chief supply of such young-rooted plants. Spring propagation is often a matter of uncertainty, but, as fine a lot of *Calceolaria* cuttings as I ever beheld, I saw last year

in the frame-ground at Battersea Park, and these were struck in February. These cuttings were selected from old plants wintered in frames, and fully exposed every fine day by drawing the sashes completely off them, consequently they were pretty hard and well-seasoned. They had been inserted in cool frames, precisely as advised for autumn cuttings, and a failure could scarcely be found even in four lights of them, and by bedding-out time they had formed very serviceable, well-rooted, stocky plants. Spring cuttings, however, are mostly rooted in hot-beds, in boxes or pans, and often as many of them damp off as survive to become plants; nevertheless, where the stock is deficient, this mode must be resorted to. It is best to strike them after the middle of March in pure sand, in a hot-bed or propagating-pit, where there is no stagnant atmospheric moisture, and, when rooted, to pot them, or put them in boxes in light sandy soil, still keeping them in warm quarters, for a few days. After that, gradually shift them into places in which there is less heat. Powdered charcoal or wood-ashes, strewed on the surface of the soil amongst the cuttings, are great preventives of damp, and a judicious use of the watering-pot should be exercised.

W. F.

A SPRING FLOWER BED.

I AM glad to find your artistic correspondent, Miss A. Hassard, recommending spring bedding, and I am sure that her arrangement of colours must be perfect. The accompanying plan, but

little altered this winter from last spring, was so much admired by some of my friends, that I venture to send it to you. The oval is cut on the turf, the grass on the inside being slightly raised. In the centre stands an inverted root of a tree, about 3 feet high, densely clothed with Ivy, which hangs in a fringe all round; the inside of the root is filled with *Centaurea candidissima*, which gives it a cheerful appearance in winter, and, should it survive till spring, will furnish abundance of cuttings. In the oval, the curving lines 1 and 2 are crimson and white Daisies alternately crossing each other (8 inches wide); 3, (of which there are eight small ovals) is Pansy Imperial Blue Perfection (Henderson); 4, Pansy Sunset, bright yellow with black eye; 5, a large blackish-purple Pansy, found by a neighbour in an old-fashioned garden, and increased by him. It is a far better bedder than the well-known Cliveden Purple. 6, Pansy Cliveden Blue. This forms the groundwork of the whole bed. All the Pansies and Daisies are planted thickly, which ensures a mass of bloom. All my other Pansy and Daisy spring beds are arranged in patterns, except where Tulips are used, when one variety only is planted as a groundwork. The oval before mentioned is nearly 5 feet in width of the flower-belt, and between 40 and 50 feet in extreme length. PANSY.

Cytisus fragrans.—This makes one of the prettiest of all early spring blooming window-plants, and deserves to be more extensively grown than it is for this purpose. It bears an abundant supply of sweet-scented yellow flowers, and is easily grown in any ordinary apartment. All the attention it requires is to cut it down after flowering, and either to syringe or sprinkle the plant every day while making its young growth. It does well in any room window if protected from frost.

GARDEN DESTROYERS.

SLUGS AND SNAILS.

THESE are often troublesome, both in our outdoor and indoor gardens. They are equally at home in the plant-stove or Cucumber-house, with a winter temperature of 70°, or under a hand-light of Lettuce or Cauliflower plants, silently doing their work of destruction, unless prevented by hard frost. The means required for the destruction of these and other garden pests are almost as varied as the different plants and situations to which their depredations are extended. There are few Orchid-growers who have not had cause to lament their presence, in the shape of young growths, flower-spikes, and roots eaten off; for here their operations are not interrupted by excessive droughts or pinching frosts. The wonderful powers of instinct possessed by even such pests as these are scarcely known to those even who make their habits a life study. In the open air, where slugs and snails are more numerous, and where their food abounds in greater quantity than in plant and fruit houses, we have not an opportunity of fully seeing how they are attracted to a given spot where food suited to their taste exists. A bed of crisp Lettuce, Cabbage, or a row of winter Celery is a favourite haunt with them. Here, however, it might be supposed that, in their nightly peregrinations, they accidentally discovered their feeding-ground; but, in the Orchid-house, the power which they exhibit of discovering food which they like is a subject for contemplation. I have often observed that a slug will travel over the surface of a pot in which is growing a *Dendrobium nobile*, a *Cattleya*, *Vanda*, or similar upright plant, for a score of times without ever attempting to ascend into the head of the plant—unless it is in bloom, in which case they are certain to find their way straight to the flowers; after which they will descend, and return to some favourite hiding-place, often at the opposite end of the house, returning regularly every night to feed on their dainty dish, unless means are taken to cut short their career. Being animal as well as vegetable feeders, they are extremely fond of fat. I have frequently dropped tallow about in places where they were least likely to find it, but seldom did many nights pass before they made its acquaintance. Slugs do serious harm in the Orchid-house by eating indiscriminately whatever young roots are made above the surface of the soil, as well as young growth and flower-spikes. They do not often exist here in great numbers; but a few continually get in, often in the shape of eggs, in the potting materials, or they find their way in under the doors. As soon as the unmistakable slimy trace is apparent, the best way is to get a few sweet Apples, if in season—of these they are very fond—slice them and lay them about plentifully; look them over two or three hours after dark, when the slugs are almost certain to be caught feeding. Small bits of fat meat or crisp Lettuce leaves can be used in the same way. There is a small snail, not more than three-sixteenths of an inch in diameter, which, when full grown, smells strongly of Garlic if crushed. If numerous, it is very annoying, eating the flower-spikes and young growth when they first begin to push. Sliced Apples or Potatoes should be laid about in quantity on the surface of the pots, looking them over in the morning, and an hour or two after dark; perseverance in this way will shortly rid the Orchid-house of their presence. If tan is allowed to lie for any considerable time after it is taken from the pits before being used, it is sometimes much infested with this species of snail. I have seen it introduced by thousands in this way into a pit of fruiting Pines, and, when they began to push, the snails set to them in such quantities as to cause every fruit to become deformed. In the Cucumber and Melon-house, and in pits and frames devoted to the cultivation of these plants, slugs are generally troublesome, finding their way in among the fresh soil, which is frequently required in such houses. The best way is to constantly keep some of the materials advised for the Orchid-house laid down to entice them, occasionally looking them over. Pieces of board about a foot square, laid down upon the surface of the soil under which they take shelter in the daytime, make good traps. In the Mushroom-house, if troublesome, they must be sought for by candle-light diligently until caught. In Fern-houses, where masses of rock-work

exist, they are sometimes very troublesome, destroying the young fronds of some Ferns as they appear, such as *Adiantums*, *Thamnopteris*, some *Polypodiums*, &c. They have such facilities here for hiding and breeding that it is difficult to eradicate them if once they are allowed to get to a head; continual trapping with materials such as above advised, and frequent hunting for them by candle-light, will, if persevered in, clear the house of them.

Slugs Out-of-doors.

It is out-of-doors, however, that they exist in quantities, and it is here that they frequently sorely tax both the patience and the perseverance of the gardener. It is often said that slugs and weeds are the natural consequence of bad gardening; this in some measure is true, but not always. If the land is kept continually stirred by the hoe, as it should be, for the due admission of air and the destruction of weeds, slugs are destroyed thereby in great numbers; and in gardens completely walled round, and where there is no Box edging for them to harbour in, a thorough system of good culture will soon reduce their numbers so as to render them comparatively harmless. But where the soil of the kitchen-garden is of a heavy adhesive nature, and happens to be adjoining to Grass land, with only a growing fence of some kind for a division, through which they can come by thousands—as they may be seen doing on a damp April morning—the work of keeping them under is continuous. All ground that has been trenched, ridged, or dug over in the autumn, should be gone over with the pick, when hard frost occurs, turning it up roughly as deep as the frost has penetrated. This will destroy numbers. In the spring and summer some recommend a few ducks in the kitchen-garden; these will destroy very great numbers, and they will also spoil both Peas, Lettuces, and other crops, rendering their presence as objectionable as the pests which they are introduced to destroy. Numbers of slugs may be got rid of by placing small heaps of refuse vegetable tops on the ground for a few days, and then removing them to the rubbish-heap, which should always be liberally mixed with quick-lime before it is returned to the garden. But the most effectual method I have ever tried for destroying them in quantities is to procure, in April, May, or June, a plentiful supply of air-slaked lime. On a warm damp evening at dusk (if in June, after a thunder-shower all the better), take and sow by hand the whole of the garden over with lime, so as to give the ground the appearance of a sprinkling of snow. Thousands will receive their quietus on the first sowing, but numbers that have only got a slight powdering will throw off their slimy coat, lime and all. To make sure of these, the ground should all be gone over a second time forthwith; and if trouble is taken to see the effect which the second application has upon those that have escaped the first dose, it will be seen that a very small quantity destroys them, owing to their not having the power to throw off a second slimy jacket. If the colour of the lime is objectionable, a little soot may be added, but not in such quantity as to weaken the caustic properties of the lime. Two or three applications of this description during spring and summer will greatly reduce their numbers.

Plants most Liable to Attack.

Care should always be taken not to plant on the same ground two crops in succession that are particularly subject to the ravages of snails or slugs, such as Lettuce after winter Broccoli. I have seen half an acre of Peas, after winter Celery, completely destroyed, almost every Pea eaten off before they appeared above ground. In old gardens an occasional dressing of salt in the autumn or winter, half a pound to the square yard, over ground that is trenched or dug over, will greatly benefit the land as well as destroy the slugs and other pests. Slugs are amongst the greatest enemies with which the Dahlia-grower has to contend. Many make a circle round the plant with lime or soot; but this gets wet and becomes baked, and the slugs then crawl over it without difficulty; and, if the dressing is kept renewed repeatedly, it becomes injurious to the plants. The short bristle-cuttings from the brushmakers are the best material with which to strew the ground round the plants. In either a wet or dry state, this material sticks to slugs as they attempt to crawl over it. Wheat straw chopped

fine, or Wheat chaff, is also an excellent material for strewing round the collars of herbaceous plants, such as Delphiniums, Phloxes, double Rockets, or other choice plants. It is not only a protection from the slugs, but, also, from severe frost. Slugs are, often, very annoying amongst Strawberries when in considerable numbers, destroying much of the best fruit, and the mulchings required for the Strawberries are very favourable for the protection of the slugs. In this case I have found no method for their destruction equal to laying down every two or three yards, amongst the plants, a piece of flat tile, and looking these over twice a week through April and May. An active boy will go over a considerable breadth in a couple of hours, dropping the slugs into an empty flower-pot, or any vessel in which they can be taken and destroyed. If this is persevered in, by the time the fruit ripens they will be reduced in number so as not to do serious damage. In gardens that have been neglected, where slugs abound in large numbers, it frequently happens in a damp and showery spring that it becomes almost an impossibility to plant anything out in the shape of Cauliflowers, Cabbage, Lettuce, or anything they will eat. You may strew the ground with wood or coal-ashes amongst the young plants, dust with lime and soot until the plants are so overdone with it that they refuse to grow, and still find it impossible to keep the slugs in check. In such cases there is no resource but hand-picking morning and evening. This slow and unsatisfactory business should, however, be dispensed with as soon as their numbers can be reduced by the more general means already advised, and, above all, by adopting a thorough system of cultivation. Deep trenching buries great numbers of both them and their eggs, so deep as to cause them to perish. The removal of all refuse vegetable matter as soon as the crops are cleared, keeping the ground, as far as possible, amongst growing crops continually stirred, as also all ground from which the crops have been gathered—this, more especially in dry weather, is destructive both to them and their eggs, exposing them to the scorching sun, and to their natural enemies the birds.

Large Wall-snails.

The large wall-snail, that bears its house on its back, is sometimes very troublesome, especially on Peach or Cherry walls. If left unchecked in spring, it quickly denudes Cherries of their leaves whilst they are young and tender, doing serious mischief. The growing fruit of Nectarines, being, unlike the Peach, smooth, is an especial favourite with them. It is surprising the damage half-a-dozen of these snails will do, every night breaking into a number of fresh fruit; and they are by no means so easy to find as might be supposed. They get under the leaves and behind the branches, and continue their depredations until the last fruit is gathered; and, when ripe, attacking Peaches and Nectarines alike. In the winter they take up their abode in any open joint in the wall where the mortar has become defective, under the coping, or right over the wall at the opposite side, or under anything that may be lying near the foundation under which they can pass the winter. The best traps I have found for them are empty Seakale-pots, with the lids on, placed on the ground at intervals of a few yards on each side of the wall, a little before the leaves begin to fall. If these are examined once a fortnight during the autumn, the snails will be found attached to the inside of the pots, and before Christmas not many will escape. At the same time, every crevice in the wall on both sides should be carefully looked over, for a number of the small fry will be in existence, and must also be destroyed.

T. BAINES.

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

Moles in Flower-beds.—I shall feel much obliged to any of your correspondents who will kindly inform me of some effectual means of getting rid of these troublesome little burrowers. I have tried an iron spring-trap without much success.—G. S. W.

Traps for Catching Blackbirds.—I beg to inform your correspondent "R" (p. 162), that the steel or iron rat-traps for catching blackbirds may be obtained from any ironmonger in his neighbourhood. They are only the miniature steel traps, so commonly used by ratcatchers, the larger ones being used by gamekeepers for catching rabbits, cats, and other vermin. I find the best bait for tying on the plates of the traps is a small piece of a ripe Apple or Pear, these being tougher to peck at than Gooseberries or Currants; and the blackbirds, in their efforts to devour them, are invariably caught by their necks or head, and killed instantly.—WILLIAM TILLEY, *Welbeck*.

THE GARDEN IN THE HOUSE.

NATURE-PRINTING LEAVES AND GRASSES.

BEFORE proceeding to give the following directions for nature-printing Ferns, leaves, Grasses, &c., I will make a few remarks on the machine for applying the necessary pressure; and, also, on the paper. I use Bradford's No. D. roller-press, which is better known in the laundry than in the printing office. It consists of two 12-inch India-rubber-cased rollers fixed in a strong wooden frame, with screws to fasten it to a piece of wood projecting from a wall. The pressure is obtained by means of a strong spring and screw, which are put in motion by turning a handle. Now, I am not sure that better impressions could be obtained by using a higher class machine, such as a lithographic press for instance; I think, perhaps, it might be more convenient in working. To those who have one at command, I would say, try it; I have not had the opportunity, I have used an ordinary copying press, but the prints are wanting in sharpness. With regard to the paper, choose that of a fair quality, and free from manufacturers' marks; I think it is called, in the trade, "wove-paper." Albumenised paper answers well, and gives a photographic appearance to the print, but it is too expensive for general use. The size I have found most convenient, and quite large enough to take a good specimen of most Ferns, is $17\frac{1}{2}$ by 11 inches the half sheet. If it is desirable to use a larger frond than the half-sheet will take in, I double it previous to drying, of course arranging it so that the character of all its parts may be seen; or I cut it in half and take a print of each part on separate papers, which I have only to lay end to end and I get a full-length portrait. The necessary articles are rather numerous, but, with the exception of the press, they can be had for a few shillings. The price of the press I have just described is £2 2s.

As regards requisites, I get a small jar of printer's ink (black) a little linseed oil, a 5-inch roller, such as is used by printers; a piece of smooth slate, about 16 by 6 inches; an old table-knife, worn thin; a paper-knife; a quantity of paper, as previously described; four pieces of thin card-board, $18\frac{1}{2}$ by 12 inches; two pieces of chamois leather, and a press. Cut the two pieces of leather a little smaller than the card-boards, take two of the boards, lay a leather on each, then stitch the board and leather together all round the edge, at the same time stretching the leather, just a little, to take out the wrinkles. This pair of boards I shall now call pads for the sake of distinction. The other pair may be fastened together with two or three strips of tape, so as to resemble a book-cover. Procure the fronds, leaves, or whatever is to be printed, dry them between sheets of blotting-paper under heavy pressure. If the rachis, or mid-rib, is too thick (as will be seen if the parts near it do not come out clearly in the print), it must be cut thinner with a sharp knife, taking care to preserve the scales on the part left.

All being ready, proceed as follows:—Put a small quantity of ink on the slate, add a few drops of oil, and mix well together with the knife, then take the roller and work the ink all over the surface of the slate. I cannot give the exact proportions of ink and oil; the proper consistency will soon be found by a little practice. Now, the ink must be taken from the slate to the pads, which is best done by working the roller alternately on the slate and the leather until the ink is evenly distributed over the latter. Lay the pads together and pass them several times through the press, in order to get the ink well in. After this, just a touch over with the roller occasionally will be found sufficient. It is necessary to have an assistant (a little boy would do) to attend to folding the paper and to pass it through the press &c., as it is impossible for one who does the inking to keep his hands from being soiled. So far, all has been preparation, and some may think it rather a long one; but it is not so much to do after all. Now for the actual work. Lay the dried frond or leaf between the pads, and pass them two or three times through the press. Then separate them carefully. If the frond adheres to the pads, the paper-knife will be found useful. Let your assistant open a sheet of paper and lay on the clean pair of card-boards, place the frond in the middle of the half-sheet and fold the other half over it, also fold the boards, and pass them once through the press. Remove the frond and two faithful prints will be the result.

Should they, however, be a little too black, which is sometimes the case, take another impression without re-inking the frond. In this way, I have frequently taken four; of course, each is a little lighter than the preceding one. It will be seen that the same frond may be used till some accident renders it imperfect. Care must be taken that nothing gets attached to the frond, for so fine a thing as a hair would spoil the otherwise beautiful prints. Anyone having a machine, the rollers of which are not cased with India-rubber, may get on capitally with a piece of sheet-rubber the same size as the card-boards, cutting it half through down the middle, so that the part uncut may act as a hinge. Place the boards containing the frond or leaf within this, previous to putting it through the press. I forgot to say that the ink takes better if the paper is damped a little. The prints must be thoroughly dried before being laid together.

Teignmouth.

THOMAS SMITH.

WREATHS AND GARLANDS.

THESE rank among the prettiest styles of floral decorations, their only drawback being that some practice is wanted to make them nice and light-looking. Long pieces of wire are required for the foundations, and some bundles of Moss to keep the stems of both flowers and Ferns fresh. There are so many flowers suitable at all times of the year for this kind of decoration, that I need not enumerate them, as the selection must depend on the size and description of the wreath or garland intended to be made, and, as a rule, light and airy-looking flowers are the best to select. As each flower is bound on to the foundation after having been previously wired, it should be drawn out into the required position, and plenty of damp Moss should be bound round its stem, so as to preserve its freshness. For small sprays, use very little Moss, for, were it to appear, it would tend to make the wreath look heavy, but in a large garland its appearance does not matter so much; indeed, if the Moss is fresh and green, its being shown will be an improvement. Though the Moss should be damp, permit no water to remain therein, beyond what does so when pressed, after being washed, for, if water is allowed to drip from it, it would spoil anything the garland might happen to touch. A few sprays of *Lygodium scandens* look light and elegant twined through wreaths of any description. Heavy flowers should, as a rule, be avoided, as, though in themselves they may be handsome, they tend to give a heavy appearance to the wreath, which no amount of dressing with Ferns or other foliage will obviate. I am of opinion that if fewer *Camellias* were employed, and more of other flowers substituted, such as *Bouvardias*, *Stephanotis*, &c., wreaths that are exhibited in the florists' windows would often have a lighter and more elegant appearance than they sometimes present. Sprays of Ivy intertwine charmingly in this style of decoration; but young sprays of a good colour and with small leaves should be selected. Another creeper admirably suited for this purpose is the Japan Honey-suckle.

A. H.

HOW TO ARRANGE VIOLETS EFFECTIVELY.

THESE charming little flowers are difficult to arrange, so as to be effective, owing to the slenderness of their stems, but this difficulty may be obviated; and Violets, when properly treated, will last in perfection for a considerable length of time. The usual way in which Violets are attempted to be kept fresh is to put them in water tied up in the bunch, as when bought, but the stems are never all of the same length, and the consequence is that, in reality, only about half of them reach the water, and the other half becomes withered, causing the whole bunch to be thrown out as dead, whereas only half of it is in that condition. The style in which I like best to see these

simple little flowers arranged is as follows:—Take an ordinary saucer and fill it with fresh-looking Moss, such as grows in woods or is sold in the market in bundles, and which has previously been well washed; build the Moss up in the form of a little mound in the saucer, keeping the fresh points of the Moss to the front, so as to make it look as fresh and velvet-like as possible. The water should be well pressed out of the Moss, but enough moisture should be left in it to keep the flower-stems placed in it fresh. Round the edge of the saucer Fern fronds should be arranged, so as to hide the china; and, for this purpose, the tips of the common Brake are best. Then take the Violet blooms and make them into bunches, say, eight or ten in each bunch; their stems should be then bound together with a piece of binding wire. The binding wire, besides keeping the stems together, makes them firm, and renders them capable of being bent into any position required. When as many of these little bunches are made as are considered to be sufficient, they should be dotted over the ground-work of green Moss. A few Snowdrops, if procurable, placed here and there amongst the Violets, produce a charming effect, and a mixture of white Violets also looks very well in an arrangement of this description. The addition of a few fronds of Maiden-hair Fern, too, tends to lighten the general effect. The Moss should be well damped every morning, and, if this be not forgotten, the Violets will keep fresh and emit their sweet perfume for many days. Some use the leaves of sweet-scented *Pelargoniums* in place of Fern fronds, but the perfume of the *Pelargonium* leaves quite overpowers that of the Violets, therefore Ferns are best, and there are few places in which a frond or two of them cannot be had.

A. HASSARD.

Upper Norwood.

A Floral Wreath.

Sibthorpia europæa as a Window Plant.—This pretty little plant is, perhaps, better suited for the window than for either the flower-garden or conservatory. It is easily cultivated, being particular neither as to soil nor situation; it seems, however, to like a sandy loam mixed with leaf-soil, or decayed manure best, and the more light and air it gets the better it thrives. During late spring and summer it requires plenty of water, but in winter it should be kept moderately dry. When it begins to make fresh growth, it should be re-potted; shake away part of the old soil, use fresh material and re-pot in the same sized pot in which

the plant was formerly growing. In the event of any of the plants, at re-potting time, being too large, divide them into two or more pieces, and pot each portion separately. Shorten back the old growths at potting-time, so as to induce the plants to break afresh. They may be readily propagated by means of cuttings, divisions, or seeds. They thrive apace either in stoves, cool green-houses, frames, or windows, but, under all circumstances, the pots, or baskets, containing them should be suspended, so as to permit the Moss-like growths to hang over the edges, and form a dense drooping coverlet for the pot or basket. Coconut-shells, or any other little ornamental pot or basket, may be used for this *Sibthorpia*, which is one of those plants that grow better alone than when associated with other plants; therefore, small pots or baskets should always be used for it in preference to large ones. When at the Lawson Nurseries, Edinburgh, a short time since, I saw some hundreds of a variegated form of this plant. Its leaves were deeply marked with pure white; and, if anything, I think the habit of the variegated sort is dwarfer and more compact than that of the common green-leaved kind.—W. FALCONER.

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE

***Sonchus laciniatus pinnatifidus*.**—This is a very graceful plant for dinner-table decoration, as, having such finely-cut leaves, it has a beautiful light-looking appearance. It is a plant of quick growth, and is easily increased by means of cuttings or seeds.—R. H. B.

Button-hole Bouquets.—Very pretty little bouquets of this kind may now be seen in the shop windows and also in Covent Garden Market. A very effective one may be made of white Hyacinth flowers, and a bloom or two of *Scilla sibirica*, or white Hyacinth, and a pip or two of *Euphorbia jacquiniæflora*, backed in both cases either by a fresh Rose-leaf or Maiden-hair Fern. The Rose-buds with their own foliage are always fresh, fragrant, and effective, and few button-holes equal these for the winter months.—B.

THE ARBORETUM.

ON THE TENDERNESS AND DECLINE OF THE LARCH IN BRITAIN.

I REJOICE to see that this subject is attracting the attention of your correspondents. I have been a close observer of arboriculture in Scotland—no less than in the north of England—during fully fifty years, and began to plant Larches myself as long ago as in 1825 and 1828. Even at that time young plantations containing this popular tree, of which all were so confident in their praises, occasionally exhibited unexpected signs of sickness, though the older woodlands on all sides of them, which had been formed twenty years previously or more, were full of fine robust Larch trees. In 1830, I saw the then magnificent forests of Dunkeld and Blair Athol; but even then great misgivings were beginning to be felt by planters in the Lowlands, and not always to be accounted for by the tree having been placed on dead-flats, on heavy tills, or on poor ferruginous sub-soils unsuited to its Alpine nature. Ominous whispers were rife that the young Larch plantations were no longer healthy and prosperous, like those of an earlier date, but were liable to a peculiar kind of “blight,” and to a fungus upon the stem. Afterwards came tales of downright destruction of the saplings by frost in various places, and then we heard an alarm about a new malady of ulcerated stems and effusion of resin on the diseased parts. All these appearances were regarded as specific maladies or diseases. They were never perceived to be consequences of weakness and tenderness in the constitution of the plants affected, and especially presenting themselves after the young trees had suffered from frost-bite. Blights, whether of an animal or vegetable character, readily develop themselves upon the surfaces of the trees so weakened, and, with their sap, perhaps, chemically altered by the cold they have only barely been able to resist. Individual plants of hardier constitution will be seen altogether free from blight, from fungus, and from ulceration. The Larch forests in the Tyrol are full of instruction to the arboricultural traveller, as I can personally testify. Nature never scatters the seeds of her own majestic trees from out of the cones until the latter are opened by the warm vernal sun in March and April, that is to say, not until the seeds themselves have been thoroughly wintered upon the trees, and their maturity confirmed by the severe frosts of the climate; whilst they continue to imbibe the resin and essential oils peculiar to their species. Compare such seeds, extracted by sun-heat from cones gradually matured until March, with the produce of British or North-German plantations, gathered, half-ripe, in November, from inferior trees, and then kiln-dried in order that the immature cones may be made to open and yield up their contents. Even if gathered in the Tyrol itself in November, they are not ripe.

Can any one wonder that our Larches are now poor sickly plants, ready to perish from frost-bite or chilblain, which mother Nature vainly strives to medicate and heal by resinous effusion? In the so-called Larch-disease we find the ever-repeated old story. The after-symptoms of the malady are mistaken for the malady itself. Tenderness is the disease; cold is the destructive agent; ulceration and fungus are the consequences; and resinous effusion and intumescence are Nature's efforts to heal the sore. Good and sound seed, from our British woodlands, may be procured in limited quantities from the summits of healthy Larches, when felled in February or March, after the cones have been fully wintered, and exposed to every frost and storm upon the trees. They may also be gathered in February or March from the pendulous side-branches of healthy trees. The largest cones, and the reddest or brightest, are ever the best. Extract the seed by laying them in the April sun upon a sheet, on the floor of a room or of a greenhouse. Give them two or three weeks to open, sprinkle them, at intervals, with water from a pan with a rose, in imitation of April showers, and at last thresh the cones with a stick repeatedly. The seeds must be sown very shallow, and as thick as may be, in some half-shaded situation in the garden, say, under an east or west wall, and carefully protected from chaffinches for some time after the plants have appeared. This is the way by which healthy Larches may be procured

in small numbers, to be used as principal trees, and carefully inserted in favourable localities in our woodlands. And, if we be willing to pay a proper price, similar plants will in time be supplied by nurserymen, both from British and from Tyrolean seed, in considerable numbers. But it is doubtful whether we can wisely adhere to the practice of using Larch as a cheap nurse-plant for Oak and other hardwood. At all events, let us understand that the ordinary seedlings are only good by accident, when they happen to come from well-wintered seed, and from healthy parent trees. And here let me recommend a more general use of the Scotch Fir and the Spruce as nurse-plants. Moreover, we possess, both in England and Scotland, a valuable but neglected variety of the Birch, very superior as a nurse (to Oak, Ash, &c.) to the white or ornamental Birch commonly cultivated, but which last grows much too quickly and too tall for an efficient nurse. The variety desiderated is the common brown Birch of our open plains, which we see among the Oaks and Hazels in so many coverts, holts, and thickets. It comes sufficiently true from seed, though differing only as a variety from the white Birch, and united with it by intermediate crosses or sub-varieties between them. But this common brown Birch is the hardiest of all, and is the most ready to reproduce itself as coppice, which is a great merit. It does not become too tall and domineering like the graceful and pendulous white Birch, which has been far too exclusively cultivated. The brown Birch is rigid and erect, of lower stature; its bark often partly brown, partly white. Another nurse-plant of great value is the Silver Alder (*Alnus incana*), a native of Sweden, of Germany, and the Tyrol. It is as hardy as the Birch, and does not require so moist a soil as the common Alder. It both ripens seed well and throws up numerous suckers, so that it is quickly becoming known to planters. In conclusion, let it be remembered that cones of the Scotch Fir, or Pine, are never truly matured until February or March. If we gather them in autumn, we are sure to propagate an inferior and tenderer offspring, which will probably prove short-lived. Early luxuriance is no recommendation. Spruce-cones must be gathered up as they fall from the trees, during winter or in early spring. The cones of both these trees open readily in the sun. As a general rule, the cones of all exotic Coniferæ should be allowed to hang as long as possible, to be thoroughly matured by time and frost, ere we cull them.

R. C. E.

THE FEVER GUM-TREE.

THE many very interesting accounts which have been published with regard to the *Eucalyptus globulus* do not seem to have exposed all of its values. And we find in “Comptes Rendus,” of October 6, a note presented to the French Academy of Sciences by M. Gimbert, in which he describes another value equally as great as those with which all are so familiar. From reports received from various reliable sources, it seems to have been determined that in localities where the *Eucalyptus* flourishes there has been a complete disappearance of intermittent fevers. “A tree,” says the author, “springing up with incredible rapidity, capable of absorbing from the soil ten times its weight of water in twenty-four hours, and giving to the atmosphere antiseptic camphorated emanations, should play a very important part in improving the health of malarious districts.” It has the property of absorbing, directly and rapidly, the water of shallow marshes, thus preventing fermentations which are produced, and paralysing the animal miasma proceeding from them which might arise from them. The predictions with this regard, which were made in 1869, have in all cases been realised. The author furnishes a few of the numerous results, which are very interesting. The English were the first to experiment in their sanitary plantations in Cape Colony, where they were eminently successful. Two or three years were found sufficient to change the climatic conditions, and the aspect of the malarious districts of their possessions. Some years ago the Algerians took occasion to spread the *Eucalyptus* throughout the French possessions in Africa, and the following are some of the results obtained, as communicated by M. Trottier:—“About twenty miles from Alger, at Pondouk,” he says, “I owned a property situated near the river Hamyze, the emanations from which produced intermittent fever among the farmers and their servants every year. In the spring of 1867 I planted upon this farm 13,000 plants of the *Eucalyptus globulus*. In July of that year—the season in which the fevers appear—the farmers were completely free from them. In the meantime, the trees had scarcely attained a height of more

than 8 or 10 feet. Since that time the settled population has been entirely free from fevers." Fourteen thousand Eucalyptus trees were planted upon the farm of Ben Machydlin, in the vicinity of Constantine. It has for several years past been noted for its insalubrity, being surrounded with marshes throughout the entire year. The trouble entirely disappeared, and the soil became perfectly dry in five years. The atmosphere is constantly charged with aromatic vapours, the farmers are no longer troubled with disease, and their children are bright with health and vigour. The operations of the manufactory of Gué in Constantine were rendered wholly impracticable during the summer on account of the pestilential emanations from the marshes with which it was surrounded. M. Saulier conceived and put into practice the idea of planting a large number of Eucalyptus trees in these marshes, and in three years about 12½ acres of the marshy soil were converted into a magnificent park. The water completely disappeared, and the health of the workmen has since been in good condition. In consequence of the large grove of Eucalyptus globulus on the farm of Maison-Carrée, which is situated in a district in which the inhabitants formerly succumbed to the malaria, similar hygienic revolutions have taken place. It is stated by land-owners in Cuba, that, there also, the paludal and telluric diseases have disappeared from the malarial districts where the Eucalyptus has been cultivated. According to Ramel, Australia is very healthy where the Eucalyptus flourishes, and unhealthy where the tree is not found. On the banks of the Var, near the entrance of a railroad bridge, is situated a garrison-house, near which earth-works were thrown up to dam the river in order to build the bridge. The malaria arising from it made it necessary to change the guard each year. Two years ago, M. Villard, the engineer in charge of that section of the road, planted forty trees in the vicinity of the building, and since that time this post has been the most healthy in the country. These evidences fully establish the fact that the Eucalyptus globulus has a good effect in preventing the spread of malarial diseases, and that it may serve decidedly practical purposes in this particular. Throughout our entire South and South-west many valuable enterprises have been wholly impracticable from causes stated above; and, if the examples thus set before us were followed throughout the South, there is no doubt that many of the dismal, swampy, and marshy districts, hitherto entirely worthless, may be transformed into beautiful, pleasant, and healthy sections.—*Monthly Report of the Department of Agriculture.*

Thujopsis dolabrata from Cuttings and Grafts.—This Conifer may be readily raised from seeds, cuttings, and grafts, but the two latter methods are practised most. I find cuttings, too, make the best and longest-lived plants, and they strike freely if taken off in August and September, and inserted in pots filled with sandy peat, surfaced with sand, and half filled with crocks. The cuttings should be pricked thickly and firmly into the pots, and the pots should afterwards be placed, for the next two months, in cold frames, when, if the cuttings have callused, they may be removed to a close and gently heated pit, so as to induce them to root. When rooted, they should be removed to a shelf in the pit, and, after a few weeks, transferred to another pit or frame, and, if the cuttings are in a thriving condition by next spring, they may be potted off singly in small pots. When grafted, I find that, although the stock and scion unite kindly enough, and, under favourable circumstances, grow well together for a few years, the union is never so complete as to ensure permanent success, for a rough blast of wind or unfriendly touch soon snaps them asunder; whilst other Conifers, side-grafted in the same fashion and treated in the same way, are almost as strong at their union as elsewhere. I should advise those, therefore, who purpose grafting this Conifer, to graft it close to the ground, and, in re-potting or transplanting, to plant deeper each time than before, so as to encourage the emission of roots from the scion, which in this way will ultimately be able to support itself independently of the stock.—FORRES.

Red Pine.—What is the botanical name of the Red Pine from British North America? Is it the *Pinus australis*, or Long-leaved Pine, which is described by Mahan (an American civil engineer) thus:—"This tree has but little sap-wood, and the resinous matter is uniformly distributed throughout the heart-wood, which presents a fine compact grain, having more hardness, strength, and durability than any other species of the Pine, owing to which qualities the timber is in very great demand." This author, though an American, does not mention Pitch Pine. Are there the following four distinct Pines from America:—White Pine, Yellow Pine, Red Pine, and Pitch Pine, and what are their botanical names?—L. [The Red Pine is not the *Pinus australis*, or Long-leaved Pine of the Southern States; it is *Pinus resinosa*, and forms dry woods from Maine to Pennsylvania, westward to Wisconsin, and northwards. It is a tree of

50 to 80 feet high, belonging to the Scotch Pine section, with leaves in twos, and has reddish and rather smooth bark; the cones are about 2 inches long, and sometimes aggregated in large and close clusters; it has been erroneously called the Norway Pine. The colloquial names, mentioned in the above inquiry, do all occur in North America, and most of them represent more than one species of Pine; for they have been carried with them by the settlers to California, and there applied to other trees of allied nature which occur there. The White Pine is the name applied to the Weymouth Pine (*P. Strobus*), and in California it is transferred to *Pinus monticola*. The Yellow Pine is the name applied to *Pinus mitis*, which occurs in the southern parts of eastern America, on dry and sandy soil, and reaches westward from New Jersey to Wisconsin. This is a valuable timber, durable, fine-grained, and fitted for flooring, &c. In California, the name Yellow Pine is usually applied to the *Pinus ponderosa*. The Pitch Pine is *Pinus rigida*. It extends along the eastern coast of North America, from Maine to the west of New York, and southwards, common on spare sandy rocky soil. This species belongs to the section with leaves in threes. The *Pinus australis*, also, is sometimes erroneously called the Pitch Pine.—A. M.]

Ornamental Peaches.—Of these, several varieties were sent out last spring by Mr. J. P. Berckmans, of the Fruitland Nurseries, Augusta, Georgia, who has a fancy for getting together the unusual forms of the Peach. Some are worthy of a place in a collection of ornamental trees. The pyramidal would hardly be taken for a Peach-tree if one was not near enough to see the character of the leaves. Its branches all turn upwards, and the general aspect is that of a Lombardy Poplar. The purple-leaved was rather a disappointment. Its leaves, to be sure, are purplish-red in the spring, but it loses its colour as they mature, and the tree is then as green as any other. The young leaves of the second growth are also coloured. The Australian dwarfs are very promising. These are said to have originated from the Peen-To, the flat Peach of China. Two specimens that I have are beautiful bushes; the joints are so close together that the foliage is singularly crowded. They have not bloomed yet, but are said to have double crimson flowers and good fruit. Mr. B. sent me leaves of a curious cut-leaved variety, which he discovered in a bed of seedlings, and which we may hope to know more of.—*Agriculturist.*

Cost of Planting the Paris Boulevards.—The following items of the cost of planting a young Chestnut or Plane-tree (say, three or four years old) on the Boulevards of Paris, are given in a late number of *La Municipalité*:—Excavation of the ground, which is generally heavy, 15 mètres, at 4f. per mètre = 60f. The same quantity of vegetable soil to re-place that taken out, at 4f. per cubic mètre = 60f. A prop for the tree, 13 to 19½ feet high = 1f. 50c. Drainage, by means of earthenware tiles = 11f. 15c. Pipes for supplying water = 2f. 50c. Cast-iron grating round the base of the tree = 46f. 69c. Carriage of the tree and the prop, and placing them in position = 5f. Iron guard round the tree = 8f. 70c. Cost of the tree = 5f. Workmen's wages = 1f. 69c. Annual interest on the cost of every tree that has to be re-placed in twelve years = 18f. Total, 220f. 23c. From this is to be deducted the value of the soil excavated = 18f. 23c., leaving 202f., or £8 1s. 7½d., the net cost of every tree planted.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Kolreuteria paniculata.—To what height does this grow—does it blossom and is it hardy and ornamental?—SUBSCRIBER. [This Chinese tree is perfectly hardy in the south of England, where it grows to a height of some 30 feet. It bears foliage not unlike that of the common Ash, and terminal panicles of yellow flowers, which are succeeded by bladder-like fruits. The tree is very ornamental, and may be seen at Kew.—ED.]

A Swarm of Squirrels in an Old Oak Tree.—Some men felling timber in a wood near Cudham, Kent, the other day cut down an old hollow Oak tree, when upwards of thirty squirrels rolled out, most of them dormant or in a state of semi-sleep, but, upon being roused, they dispersed to various parts of the copse. A large stock of Nuts and Acorns was found, stowed away in the hollow of the tree, which had been collected as a provision for the winter. It is common to find squirrels laid up for shelter during winter, but it is seldom such a swarm is found together.

Vitality of Tree Seeds.—An instance is mentioned in the *Prairie Farmer* by Dr. Hubbard, where seeds of the Burr Oak, buried beneath the surface of a well-drained piece of land, remained thirty years in a dormant state, till thrown up nearer the surface, which caused them to germinate. It is familiar to nurserymen that Peach stones buried compactly a foot or two below the surface will remain dormant for a time, and it would be an interesting subject of enquiry to ascertain to what length the period might be extended by deep and compact burying, for different kinds of tree and other seeds.

Cryptomerias and Deodars from Cuttings.—Can I increase these by means of cuttings, and, if so, at what season should I attempt the operation, and in what aspect should they be planted?—SUBSCRIBER. [Cuttings of *Cryptomerias* and *Deodars* strike freely, if made of the half-ripened shoots in the autumn. They should be inserted in a soil composed of loam and silver-sand in equal proportions, and placed in a cold frame, facing the north. Let them be kept close and free from frost during the winter. In the following spring, if they are removed to some close pit or frame where there is a little bottom-heat, it will greatly promote their rooting.—ED.]

A NEW RHUBARB (*RHEUM OFFICINALE*).

THE following information respecting the new species of *Rheum*, which is now considered to be the true origin of the Official Rhubarb, has been supplied by Professor Baillon to M. Regnaud for insertion in a new edition of Soubeiran's "Traité de Pharmacie:"—"Besides the *Rheum rhaponticum*, which yields the Rhapontic Rhubarb, Linnæus recognised four species of the genus *Rheum*, to which have successively been referred the origin of the true Rhubarbs of China and Russia. These were the *Rheum Rhabarbarum* (afterwards named *R. undulatum* by Linnæus himself), *R. compactum*, *R. palmatum*, and *R. Ribes*. The latter, to which has been attributed the origin of Persian Rhubarb—or, rather, of the products which are received through Persia—has never been more than a culinary herb. As to the three other species, they have all contributed (from the root) certain European and native Rhubarbs. A species more recently discovered in India (*R. Emodi* or *R. australe*) has, like the preceding, been considered to yield the Chinese and Russian Rhubarbs; but it would appear that it only produces a kind peculiar to India. As to the true plant, a native of Thibet, which furnishes to commerce both the Russian and Chinese Rhubarbs, it has only been known since 1867, in which year M. Dabry de Thiersant, consul-general of France at Shanghai, procured from Thibet some stalks of the species which yields this valuable drug, and which, cultivated in the garden of the Faculty of Medicine, at Paris, and in the Vallée de Montmorency by M. Girandean, have received from M. H. Baillon the name of *Rheum officinale*. It is a very large species, exceeding a man in height, and remarkable for the considerable development of its inflorescence. The leaves answer perfectly to the indications formerly given by Bokharian and Chinese merchants to Pallas and others concerning the true official Rhubarb plant—namely, that the leaves have a limb of a delicate green colour, in shape like an open fan, and also as analogous as possible to that of the leaves of the *Ricinus communis*, or common Castor-oil plant. This new Rhubarb (*R. officinale*) belongs to the same botanical section as *R. palmatum*. The dimensions of the limb of the leaf extend to nearly 3½ feet in each direction; it is, however, a little broader than it is long, and the petiole is about the same length. In the plants of it that have been raised, some leaves have been noticed which were more than 5 feet long. When the plant has become fully developed, it has scarcely any roots, for these are gradually destroyed, and the plant draws its nourishment from the soil only by small adventitious roots which could not be employed in medicine. But, contrary to the other species enumerated, and of which the root can be prepared and employed, this develops above ground a stem and cylindro-conical branches, 8 to 12 inches high, and of the thickness of an arm or a leg. These are the only portions which, cleansed from the so-called bark, divided transversely and longitudinally, and properly dried and prepared, can be used in medicine. They bear leaves, and, after the fall of these, there remains on the surface only the brown dried base of the petioles, together with the remains of the ocreæ; these vestiges together constitute the pretended bark. In the axil of each of these aerial leaves there is necessarily a bud. These acquire frequently a considerable development, and are elongated into leafy branches. Each of these buds, detached at a suitable season, will, in its turn, easily take root from its base, and may thus be used to multiply the plant."

A Decoction of *Bouvardia triphylla*, a Remedy for Hydrophobia.—A drug, which is sold under the name of *Trompantilla*, is said to be successfully used in Mexico for the prevention and treatment of hydrophobia, for which complaint it is freely given in the form of decoction. It consists of short segments of the stem and branches of this plant, varying from one-fourth to three-fourths of an inch in diameter, terete, and slightly bent. There is no perceptible odour to either wood or bark; the former is tasteless, the latter has a slight bitterish taste. The central pith is scarcely a line in diameter, and of a brownish or purplish-brown colour.

Green Lanes.—England surpasses the world in the peculiar beauty of her green lanes. Italy has its skies, Greece its classic ruins, Egypt its pyramids, Switzerland its Alps, Germany its Rhine, America its Niagara; but none of these has a green lane such as there are thousands of in England. The green lane is essentially English, and is confined to England. There are green lanes neither in Scotland nor Ireland—we mean Grassy roads arrayed in greenery, shaded by lofty old hedges, Beech trees, Alders, or Willows, leading to some quiet cot or farm-house, or range of pasture-lands; and often leading on merely to some other green lane, or series of lanes, branching off to right or left, which are there seemingly without any other purpose than that they are there, to feast the eyes of country strollers with the sight of their quiet green beauty.

SUNDRIDGE PARK GARDENS.

SUNDRIDGE HOUSE is pleasantly situated in a finely undulating and well-wooded park, and is sheltered by a sloping hillside behind. Fine specimens of Larch, Birch, Elm, Cedar, Walnut, and fine old Hawthorns are dotted here and there, singly and in groups. The common Larch as seen in the park at Sundridge is one of our finest ornamental trees, which might even be planted with good effect on lawns, where its long lower branches, being undisturbed, would sweep down gracefully on to the mossy turf; its elegant habit is best seen when contrasted with heavier round-headed trees, and when its fresh green foliage makes its appearance about April, it forms an interesting object in any landscape. Sundridge House owes much of its interest to the gracefully undulating and profusely wooded park by which it is surrounded, and from which some fine views of woodland scenery may be obtained. It is, indeed, in point of beauty, far before some Kentish parks of much greater fame. Among the finer trees in the garden we noticed a fine specimen of *Salisburia adiantifolia* 50 or 60 feet high. It is now, of course, denuded of its curious foliage, and in habit reminds one of a very fine pyramidal Pear tree, the colour of the shoots and spurs being nearly identical.

The Conservatory.

From a gardening point of view, the most attractive feature of Sundridge Park is the conservatory, and, as will be seen from our illustration, it is a very beautiful one. Our illustration represents the interior arrangement of this noble structure—one of the finest we have seen for some time, and one, moreover, which combines a handsome exterior with every quality essential to the growth of the vegetation within. The last remark is borne out by the vigorous progress made by the beautiful specimens of tropical vegetation since their introduction. The house is 100 feet in length, by nearly forty feet wide, and thirty-five feet in height, and is constructed almost entirely of iron and glass, having perpendicular sides and a curvilinear lantern-shaped roof of pleasing proportions, supported on light iron-work pillars, which also serve as supports for rare graceful climbers. The house has been designed and built by Mr. Henry Ormson, of Stanley Bridge, Chelsea, who has erected many of the best conservatories in the country. Our engraving, beautiful as it is, gives but a very faint idea of the interior, which would require at least half-a-dozen such views to do it full justice. The central portion of the house is laid out in beds, in which Palms, Ferns, Cycads, Camellias, and other rare exotics luxuriate with something of their native vigour. Around the sides, substantial stone benches have been erected for smaller decorative plants in pots, and beneath these the hot-water pipes are placed and concealed from view by a neat and ornamental cast-iron grating. The hot-water apparatus is of the latest and most approved kind, while the genial temperature maintained is amply sufficient for the choice blooming Orchids and stove plants, which are grown for the purpose of decoration in ranges of plant-houses to the rear of the conservatory. A notable feature is a pair of lean-to curvilinear-roofed houses behind the conservatory, and connected with that structure by doors opening into an alcove, very tastefully decorated with virgin cork, and planted with Orchids, Filmy Ferns, and other choice exotics, the effect of which is considerably heightened by a large mirror which extends the whole length of the alcove behind. These very agreeable adjuncts to the conservatory are very tastefully and systematically arranged in the natural style and planted out with Ferns, Orchids, and choice foliage plants, all of which luxuriate in the most vigorous manner possible. The doorways are fringed with masses of virgin cork, over which *Lygodiums*, *Ficus stipulata*, fresh green *Selaginellas*, *Begonias*, and bright-veined *Eranthemums* ramble in rich profusion, and with a vigour only attainable by planting them out in good fresh soil with ample room to extend themselves in all directions. Conservatories, arranged in the natural style and having the finest specimens planted out, are specially to be recommended, as they are not only effective, but much less trouble is entailed on the gardener than when pots or tubs are employed. Amongst the creepers

VIEW IN THE CONSERVATORY .AT SUNDRIDGE PARK, KENT.

which adorn the ornamental trellises and pillars, we may allude to a fine plant of the white-flowered *Lapageria*, 12 or more feet in height, with leaves 4 inches long by 3 inches in breadth, and of a deep glossy green colour, which betokens the most exuberant health and vigour. *Cobæa scandens variegata* is now very effective, drooping in elegant festoons from the tapering columns as shown in our figure. Among the specimen plants we may mention a fine *Asplenium Nidus-avis* with fronds fully 6 feet long. A fine pair of *Aralia japonica variegata*, and a fine specimen plant of *Dicksonia antarctica*, *D. squarrosa*, *Cyathea medullaris*, and *C. dealbata*. At the time we saw it, the side benches were gay with forced shrubs and bulbs, *Azaleas*, *Roman Hyacinths*, *Tulips*, *Scilla sibirica var. præcox*, *Schizostylis coccinea*, scarlet berried *Solanums*, and other decorative plants. The side stages are margined with ornamental wire-work, planted with fresh green *Selaginella*, and the effect thus produced is very neat and effective, contrasted with the bright-hued flowers above. What is probably the finest specimen of the Double White *Camellia* in the country is here planted out. We do not know its exact size; but perhaps Mr. Dedman, under whose care the house and collection are in such excellent condition, will enlighten us on this point, and on the history of the plant—or, rather, tree; for it is rare, indeed, one sees a finer evergreen indoors or out.

THE KITCHEN GARDEN.

VEGETABLES AND THEIR CULTURE.

By T. BAINES, Southgate.

Trenching.

WHERE good gardening is carried out, the whole of the kitchen-garden should be trenched every three years, a third of the work being done every season. Trenching a piece of ground is an operation of so common-place a character that everyone is supposed to know how to do it, in every description of soil; yet, I have frequently seen ground trenched at considerable expense, that had much better never have been touched than done in the manner in which it was; simply, through the impression that if the work was done deep enough it must be right. All the best surface soil was buried and a quantity of raw unfertile stuff was brought to the surface, in which nothing would grow until some of the soil previously at the surface was again brought up and mixed with it. Whereas, if not more than a couple of inches of this under soil had been brought to the surface, and some 4 inches more of the sub-soil loosened up with the fork and left in the bottom, it would have been in fit condition to have been brought to the surface at the next trenching. All vegetable-matter, in the shape of Cabbage-stalks, or similar refuse, should be buried in the bottom of the trench, and never taken off the land, as is sometimes done; when placed thus, deep below the surface, such material gradually decays, affording food which the roots eagerly lay hold of, helping the crop over a dry time in summer, in a way that shows its value. Strong heavy soils are much benefited by a good quantity of leaves, even a foot thick if obtainable. Being buried in this way, they not only lighten the soil when, at subsequent trenchings, they get more intimately mixed with it, but, from the first, they act as a drain to the soil above them, rendering it so much better to work than it otherwise would be. They also hold a good deal of moisture in which the roots of vegetable crops, during a dry time, delight. Judgment should also be exercised in the selection of the crops to follow each year's trenching. These should consist of the deepest rooting plants, such as Onions, Carrots, Beet, Peas, and Leeks, keeping the surface-rooting Brassica family for the shallower dug ground.

Double Cropping.

Some cultivators are fond of double cropping, but I have long come to the conclusion that there is much more of it done than is profitable, either looked at from a labour point of view, or for its returns in the shape of a crop. The system of double cropping with some things is an advantage, but with others with which it is frequently practised, it is a loss, as well as an inconvenience, preventing the ground from being so well

worked as it otherwise would be. Tall Peas and Celery often go together; unless the rows of Peas are so far asunder as to prevent the possibility of any gain in the crop obtained from a given space of ground, the Celery always suffers by the drawing effects of the Peas, and, in gathering the latter, the ground gets so trampled as to require a good deal of labour before it is fit for earthing up the Celery. In a hard winter, Celery so grown never stands the frost so well as if grown openly by itself. Peas with rows of winter Broccoli betwixt them are open to the same objection; the Broccoli gets injured in gathering the Peas, and becomes drawn, rendering it in anything but a condition to stand the effects of frost. The results of double cropping of this description is like "a wrinkle on Wrinkled Peas," with which a noted horticulturist favoured the gardening world a short time back, and which was simply to mix Dwarf Peas with tall ones in sowing, so that the sticks might carry pods lower down than it was natural for the tall Peas to bear, forgetting that the ground could only support so many and no more, consequently by sowing these dwarf Peas along with the tall ones, he must have so many fewer tall ones in each row. By growing rows of Cabbages or Winter Greens alternately with Potatoes, there is the advantage of the Potatoes receiving more room and air in their early stages than they otherwise would have, rendering them better able to withstand the attacks of disease later on in the season. I do not, however, mean to say that any amount of room that could be given will render Potatoes disease-proof in seasons when that malady appears in a virulent form; but, where Potatoes are grown with plenty of room, they are generally less affected than where space is limited. If the Potatoes are mid-season varieties—the best for cultivation whilst disease so often makes its appearance—the Cabbages get plenty of time to grow after the Potatoes are cleared off. The following crops, I have found, can also be grown together with advantage:—Tall Peas I always sow 6 feet apart, sticking them as soon as they are up, and then sowing a row of Spinach between them. This comes off before the Peas are fit to gather, does no harm, and is, so far, a gain. Celery trenches I make 3 feet wide, planting two rows in each trench, leaving 3 feet betwixt the trenches (if less than this is left the points of the roots of the Celery will be cut in earthing-up); on this 3-feet space I make a shallow trench that will hold water, in the bottom of this I sow a row of Lettuce, thinning them well out (always sow Lettuce in summer, never plant, as they bolt in half the time the sown plants do) and giving plenty of water. In this way Lettuce can be got as large as York Cabbages, and all cleared off before the Celery wants earthing-up.

Parsley.

There are few things so continuously in demand as Parsley, and a plentiful supply of it through the winter is always desirable. For many years I have never sown Parsley more than once, and never transplanted it. Onions I sow in rows a foot apart; at the time of sowing, I put a pinch of Parsley seed in a yard apart in every third row of Onions. When the Onions are thinned, the Parsley is also thinned to a single plant in each place. This does not in the least interfere with the growth of the Onions, but as their tops begin to go down, the Parsley begins to grow in earnest; and such Parsley; every plant will run from 18 to 20 inches across. About the end of October I move a quantity of these plants with good balls, filling up one corner of the ground so as to be covered with frames. Parsley grown strong in this way will not suffer from frost near so much as the poor starved stuff often met with. A good way to preserve Parsley through the winter, and anything but ugly in appearance, is to take some flour barrels, get a 2-inch auger and bore their sides with holes a foot apart every way; put 6 inches of soil in the bottom of the barrel, then draw the roots of a good plant through the bottom holes, fill up with soil till the next holes are reached, draw in some more plants, and so on, until the barrel is full, then put four or five plants on the top; place the barrels in a cool house where they can get plenty of light. The produce, in both quantity and quality, will be such as will not disappoint anyone who gives the method a trial, and they are not unsightly. The plants should be really strong for this purpose or the produce will be proportionately small. As to the cultivation, in

general, of vegetables there is nothing like growing everything in rows; it takes a little more time to sow in this way than broadcast, but it saves a great deal afterwards in labour, by the freedom with which the hoe can be used amongst the crops.

Manchester Market-gardening.

The market gardeners, who grow for the Manchester market, and the surrounding districts, manage some double crops well. The quantity of Onions, especially autumn-sown ones, for growing small in the spring, consumed in the manufacturing towns is enormous. The tons of Lisbon and Tripoli seed that some of the seedsmen sell every autumn would scarcely be credited. The ground is well prepared, generally by a crop of early Potatoes being taken off it; it is laid out in beds, 4 feet 6 inches wide, and along with the Onions is sown a sprinkling of hardy green Lettuce, and Altrincham Carrots; if the Lettuces run two or three to the square yard, and the Carrots one to the yard, they are thick enough; the beds are then planted with two rows of Strawberries, kept clear from weeds during the autumn. The first thing to come off in the spring is the Lettuce. The Onions are begun with as soon as they are as thick as a common lead-pencil, going over all the ground, taking the largest first, and so on until they are cleared. The Carrots all remain for seed, and interfere little with the Strawberries, which, being planted thin, get as much light as they require, and bear fine crops. When the Carrot-seed is ripe, it is gathered and bunched, the ground cleared, and the Strawberries allowed to remain for several years. This is the way in which the bulk of the noted Altrincham Carrot-seed is grown; but not the choicest brands," which are saved from selected roots planted in the spring, and which, for quality, colour, and general appearance, are unequalled by any Carrot in cultivation. I am not alluding to the rough green-topped roots, generally known as Altrincham Carrots; but to a carefully selected root, as smooth as a gun-barrel, nearly all the same thickness from end to end. On the sides of the beds of the spring-sown Onions is grown Horseradish, for which the Manchester market is so noted. As soon as Onions are sown, the Horseradish is planted. Whipthong-like pieces, quite straight, from a foot to 18 inches long, are planted with a dibble, slanting inwards from the sides of the beds at an angle of 45°; and I have seen Horseradish produced in this way, in a single season, 3 lbs. weight per stick, straight, and free from forks. The Celery grown in that neighbourhood is unequalled, as regards quality and appearance, by any in the kingdom, and the quantity is prodigious. The soil is superior to that with which our London market-gardeners have to deal; but, for some things, the climate is much inferior to that of London. Autumn frame-sown Lettuce for spring planting out are rarely, ever, attempted. Nothing but yellow Turnips are sown. White Turnips in the Manchester market are as unsaleable as yellow ones are in London.

Varieties.

The following is a list of the different vegetables which grow, and which I have proved to be all that can be required as to edible qualities, weight of crop, and general excellence. The greater part are established favourites, with such new varieties as are found superior to older kinds:—

BEANS.—Early Long Pod and Taylor's Large.

FRENCH BEANS.—For forcing—Newington Wonder and Osborn's early Forcing. For general crop—Long-podded Negro and Paris Red Flageolet. This is synonymous with Canadian Wonder; it is the best dwarf bean in cultivation. Excellent in quality, and a prodigious cropper.

RUNNER BEANS.—Scarlet Runner and Painted Lady. The latter, some soils sets better in extreme seasons of wet and drought.

BEET.—Barrett's Crimson. This variety should not be grown too thin in the row, or it is apt, in good soil, to get rather large. When cooked, it is a splendid colour, and it is not liable to run to seed. There is a mistake in many of the new varieties; the colour is in the leaves instead of the roots, which, when cooked, are little better colour than a common Mangold.

BORECOLE.—Buda, Dwarf Green Curled, and Cottager's Kale. In the latter I have always found two colours, green and purple, tinged. In planting, I discard the green, as it is very inferior in flavour and texture to the purple, which is an excellent vegetable, hardy, and not surpassed in flavour by anything except a summer Cauliflower.

BROCCOLI.—Snow's (true), Backhouse's Winter White, Williams's Alexandra (the best late Broccoli extant), and Purple Cape.

BRUSSELS SPROUTS.—Roseberry and Scrymger's Giant.

CABBAGE.—Cocoa-nut (Wheeler's), Early Dwarf York, Hardy Green Colewort, and Red Dutch.

CAPSICUM.—Long Red and Long Yellow.

CARROT.—French Horn and Altrincham Improved.

CAULIFLOWER.—Early London, Walcheren, and Veitch's Autumn Giant. The last is one of the most distinct and valuable vegetables introduced for some years.

CELERY.—A pink sort of my own raising; and Williams's Red and White are really good varieties.

CRESS.—Plain-leaved and American.

CUCUMBER.—Rollisson's Telegraph (True).

ENDIVE.—Green Curled and White Batavian.

LEEK.—Musselburgh.

LETTUCE, Cos.—London White, Victoria Cos (the latter is far the best Cos Lettuce, after midsummer, I have ever met with—large, fine flavour, and stands well), and Black-seeded Bath.

LETTUCE, CABBAGE.—Hammersmith Hardy Green and Wheeler's Tom Thumb.

ONION.—For autumn sowing, Giant Rocca and White Tripoli; for spring sowing, Nuneham Park and Brown Globe; and James's Long-keeping for winter and spring.

PARSLEY.—Myatt's.

PARSNIP.—The Student.

PEAS.—Caractacus, Sangster's No. 1 Improved, Advancer, and Champion of England. The above I sow all at the same time, and, by so doing, they come in nicely in succession. For later on—Champion of Scotland, Ne Plus Ultra, William's Emperor of the Marrows, and James's Prolific, which is the best of the Veitch's Perfection type, and is in every way an excellent Pea.

RADISH.—Olive-shaped Scarlet, Olive-shaped White, and Wood's Scarlet Short Top. The Olive-shaped are the best Radishes in cultivation, and will force well.

SAVOY CABBAGE.—Early Elm and Green Globe.

SPINACH.—Round and Prickly.

TOMATO.—Earley's Defiance and The Trophy.

TURNIP.—Red-top American Stove. The best for all seasons.

VEGETABLE MARROW.—Custard and Long White.

Staking Peas.—To those who have to procure stakes at a great cost, the following method will prove advantageous, being very cheap, simple, and easily performed. A few rough stakes should be obtained, and driven into the ground on each side of the row, about 12 feet apart. These stakes should be of a corresponding height to that of the Peas, and when the required number for a line is inserted, some tar-twine, or other strong cord, may be tied to the end stake, and passed along the line of stakes, making a turn on each within a few inches of the ground, and, as growth progresses, raise the next turn a little higher, advancing in succession, until the plants attain their full height. These lines being run on at the right time, the tendrils of the Peas will clasp firmly round them and support the plants quite equal to the well-known plan of sticking. Some imagine an advantage to be obtained in this way of training, as the lines get a better circulation of air, and pods can be gathered at all times without injuring the haulm.—J. C. M'A.

To Preserve Peas from Mice.—Either from their acute sense of smell, or some wonderful instinct, mice soon discover the whereabouts of Peas and other large seeds usually sown at this season. They are always more troublesome now than they are later in the season, and, it is astonishing what a deal of mischief a small number of mice will do in a short time. Red lead is a good preventive when used as a dressing for the seeds before sowing. I, however, object to using anything of a poisonous nature, when the same object can be easily accomplished by harmless and simple means; and the best and simplest means of preserving early-sown Peas, &c., is to scatter over the surface of the rows a few sifted ashes, just sufficient to give it the thinnest possible covering. I suppose it has the effect of destroying the scent; at any rate, I have never known this plan to fail. It is scarcely necessary to say anything about mousetraps, for every gardener is acquainted with the common brick-traps usually employed in the open-air. The best trap I have ever used for catching mice in rooms or buildings, is one called Pullinger's Patent; it does not require setting or baiting after the first bait of Wheat or Rice has been placed in the receptacle, as the mice cannot get at it. I have, with this trap, caught a large number of mice in a short time. In comparison with other traps it is expensive, its price being 2s. 6d.; but it is substantially made, and, with ordinary care, would last for a great many years, and would, in the long run, prove the cheapest.—E. HOBDAV.

THE PROPAGATOR.

PROPAGATION OF IVIES.

IVIES are propagated by means of cuttings, layers, and grafts. Cuttings make good quick-growing plants, and they root freely and easily; this, therefore, is the method generally adopted for increasing all the common kinds of Ivy. The variegated sorts may also be struck from cuttings, but some of the more delicate and slow-growing kinds are increased by grafting.

Cuttings.

For cuttings, select strong well-ripened shoots, cut them up into pieces about 8 inches in length, and insert them firmly in a bed or wall-border, in lines, from 9 inches to a foot apart, and 2 inches asunder in the row. Before planting, the cuttings should be cut across horizontally, just below a joint, and two or three of the lower leaves should be removed from them; the upper ones should be retained, and, if some leaf-soil and rough sand be added to the border in which they are inserted, it will materially assist them to root quickly. When cuttings are employed they should be put in in October or November, and left for twelve months undisturbed, and, unless the winter is very severe, they will require no protection, but, in the event of its being severe, straw or Fern may be strewn over them. Next autumn, lift and transplant them permanently, or set them in nursery lines a little further apart, so as to allow them to become stronger before they are finally planted out or for convenience. Nurserymen generally pot them in 60-sized pots, and keep them out-of-doors summer and winter, plunged in beds, their shoots being tied to upright stakes. They are thus always ready for sale; and, when potted, they can be turned out free from root-mutilation; when lifted, a large portion of their most serviceable roots are sometimes cut away in the operation. In planting out of pots the ball of roots should be carefully unravelled, every fibre being spread well out. Common Ivies are often struck at once in pots, and kept in pits or frames—in fact, generally underneath stages, but this is a practice not to be recommended, unless the situation is low and damp, and even then it is better to raise a bed for the purpose, a foot above the level of the alleys, than to be troubled with such cuttings indoors.

Layers.

Ivies naturally layer themselves as they trail along the ground, and, in that case, all that is needed is to cut the runner across with a spade, lift it carefully with all its rootlets attached, and transfer it to its new situation. In layering Ivies artificially, select good shoots, stretch them out on the ground, place small pots under their joints at intervals of about 15 or 18 inches apart, cut the joints half-way through and in a longitudinal direction for about half an inch; then peg these joints into the pots, which should be filled with a sandy compost, placing some sand about the incision, and cover the joints over with the ordinary soil to the depth of an inch or two. By doing this early in spring, and pinching out the point of the shoot after it begins to grow, layers thus treated will be found to be pretty well rooted by autumn, when they may be separated, and wintered in frames if badly rooted, but, if well rooted, a sheltered place outside will suit them. When very badly rooted, they may be left uncut till spring. Ivy may also be layered in the ordinary way without the aid of pots.

Grafting.

Grafting is a good way of propagating Ivies, provided suitable stocks are chosen, and, for this purpose, the common Irish Ivy is the best. Good plants from cuttings of this kind, struck out-of-doors in October, should be lifted and potted into 60-sized pots from July to October, using loam, with a little leaf-soil and sand mixed in it, and the plants should be kept in a close frame until they have made some good roots, and any that do not do so soon enough for autumn-grafting may be used for that purpose in the following spring. The chief point to be observed in grafting plants in pots is to have the stocks thoroughly established before they are operated on, otherwise they will be unable to contribute sufficient nourish-

ment to the scion. It is unnecessary, however, to have stocks so young as to be ill-furnished with roots, for, whether they are one or three years old, is matter of little importance. Side-grafting is the method generally employed, and the scions are put on close to the base of the stock; the ligatures used should consist of soft bast or worsted, and both grafting-wax and clay are unnecessary. The operation may be performed any time during autumn, or any time after Christmas onwards through the spring. A union between stock and scion is, however, sooner effected in spring than in autumn or winter; hence, spring should be chosen, as a rule, for grafting. After the operation has been performed, keep all close for a few weeks, a little warmth being beneficial, but not absolutely necessary, and, as soon as a union has taken place, unfasten the ligatures, and, when the scion has become fully established, pinch off the point of the stock, which, before that, should remain intact, and afterwards gradually reduce it as the strength of the scion advances, until it is ultimately cut over immediately above the point of union between graft and stock. At the first pinching of the stock, the plants may be taken out of close frames and placed on side-stages for a time; then let them be transferred to a cold frame. If necessary, the plants may be re-potted. The finer Ivies are usually grown for indoor decoration, but even when destined to be planted out-of-doors they are best grown in pots until they have become good strong plants, when they may be finally planted.

WM. FALCONER.

THE LIBRARY.

WHERE THERE'S A WILL THERE'S A WAY.*

IN "Where There's a Will There's a Way" Mr. James Cash has given an interesting account of the labours of naturalists in humble life—an account which should be read attentively by everybody, but more particularly by gardeners who would wish to rise in their profession. The book records the history of several Lancashire operatives, who, having, in many cases, quite accidentally, as it were, imbibed a taste for natural history, have followed it out during their hours of leisure, and in every case with the best possible results. Such achievements are valuable as indicating what may be done by means of energy and perseverance, even with appliances of the most limited character. We have little sympathy with those who wait for "something to turn up," instead of manfully striking out a course for themselves, and following it up until success crowns their efforts. If societies or clubs organised on the same self-supporting plan as those of Lancashire were diffused throughout the country, an immense amount of good might be effected. The following extract with reference to one of our best muscologists will show the style in which the author has treated his subject:—

"Mr. William Wilson, as a botanist, enjoyed a reputation hardly inferior to that of Sir William Jackson Hooker—whose intimate friend he was for many years—and others, whose names have been more prominently before the public. His *magnum opus*, the 'Bryologia Britannica,' published in 1855, is acknowledged to be the best work on British Mosses that has ever been published, and at the time of his death, on the 3rd of April, 1872, a new and enlarged edition of it was in contemplation. As a bryologist, indeed, no man living was a better authority. The late Mr. Wilson's friend and correspondent, Professor Schimper, of Strasbourg, can be said only to have equalled him, and even that eminent man yielded the palm to our countryman in the matter of manipulation. It is said that, when in Warrington, a few years ago, the professor was astonished to find Mr. Wilson sketching with one hand and dissecting with the other, and he could not find words in English to express his feeling—'Non equidem in video; miror magis.' . . . Only a fortnight before Mr. Wilson died, the publishers of the 'Bryologia,' Messrs. Longmans, wrote, saying that Dr. Hooker, of Kew (the son and successor of the distinguished Sir W. J. Hooker in the curatorship of the Royal Botanic Garden) had expressed an opinion that, as the 'Bryologia' was so frequently asked for, it would be desirable to reprint the first edition as it was, unless Mr. Wilson was likely to be able to prepare a new one in a very short time. The hopes, however, of so many friends, who looked forward to the new edition from Mr. Wilson's own hands—and for which that gentleman had spent two years in gathering material—were cruelly disappointed by his death."

* "Where There's a Will There's a Way." By James Cash. London: Robert Hardwicke, 192, Piccadilly, W.

THE INDOOR GARDEN.

TRICHOMANES RENIFORME.

THIS, to which allusion was briefly made at p. 318, Vol. IV., is one of the most remarkable of all the Filmy Ferns, and is well worth growing either under a glass shade or in a Wardian case as an ornament in a sitting-room. The accompanying illustration gives an excellent idea of the habit of the plant, of which fine examples may be found in Mr. Williams's collection at Holloway. It succeeds well in an open fibrous compost of peat and turfy loam, intermixed with a little living Sphagnum, and coarse well-washed road or river sand, to keep the whole as porous as possible. When the plant is throwing up its young fronds, it should be watered freely, taking care to use water not lower in temperature than that of the room or case in which it is growing. It should never be kept drier during the winter than in summer, but must never be allowed to get altogether dry. It should be sprinkled overhead occasionally with clean tepid water, and the glass with which it is covered should be regularly wiped every other morning. When in good condition, it is one of the prettiest of all tender Ferns.

B.

PHALÆNOPSIS.

THE different species belonging to this genus have long been considered to be the rarest and most beautiful of all Orchids; and, as no collection of the warmer-growing kinds is complete without them, a few remarks on their culture may prove useful. These beautiful plants, with one or two exceptions, come from the hottest and most humid portions of the earth's surface—viz., Java, Borneo, Sumatra, and other islands of the Malayan Archipelago; while a few are found on the Continent of India itself, their principal habitats being Moulmein, Rangoon, and the Eastern Himalaya; one or two are, also, natives of the Philippine Isles. In cultivation, they require the warm humid temperature of a plant-stove, or East Indian house; for, of all

Orchids, these are the least likely to adapt themselves to what is generally termed "cool treatment." *P. Schilleriana*, however, perhaps the hardiest of the whole group, grows moderately well in a warm Cattleya-house, or cool plant-stove, where the temperature does not descend below 50° during winter. But it is best to grow all the species together in a warm corner, where the winter temperature is regular, and never below 60°. When well-grown, few other Orchids rival these in graceful beauty, while they are not only profuse bloomers, but their delicate white or rosy-tinted flowers last in perfection for many successive weeks; indeed, it is nothing uncommon for *P. amabilis* and *P. grandiflora* to be in flower for six or eight months out of the twelve, while it is a rarity to find *P. rosea* except in bloom. Mr. Robert Warner has had over 1,000 *Phalænopsis* flowers fully expanded at the same time in his collection at Chelmsford. Young plants, with only one or two leaves, frequently throw up flower-spikes, and, if allowed to flower, they often seriously injure themselves in so doing. It is best in practice to pinch off all flower-spikes as soon as they appear, until the plant has become thoroughly well established, for nothing tends so much to weaken their constitutional vigour as early flowering. *Phalænopsis* may be propagated by dividing plants that break from the base, and some plants do so very freely, especially if the leading growth becomes checked or injured in any way, while not unfrequently some of the species produce young plants adventitiously on their old flower-stems. *P. amabilis*, *P. grandiflora*, *P. Schilleriana*, but more especially *P. Luddemanniana*, frequently throw off young plants in the way just named. When these plants commence to emit roots, they can be fixed on small flat blocks or bits of teak or acacia-wood, and left on the parent plants until

established firmly in their new quarters, after which they can be severed from the plant and treated as separate individuals. During the summer months, a little fresh living Sphagnum Moss placed around the fleshy roots of plants on blocks is beneficial, as it preserves them from extremes of moisture and exposure to the sun. Small plants do best on blocks suspended in a close warm corner of the house, and near the light. As they increase in size, they can be partially plunged in well-drained pots, taking care, however, not to hamper the roots with too great a bulk of finely-divided compost, which is apt to settle down among the drainage and become sodden, in which case the roots embedded will speedily rot. In Orchid-houses, which are naturally dry, the roots of nearly all Epiphytal Orchids seem quite willing to keep to the shade and moisture afforded by rough lumps of fibrous peat and fresh Sphagnum; but only supply them with a genial temperature, saturated pretty regularly with the soft vivifying humidity in which they luxuriate so vigorously in their native habitats, and the roots will soon creep out into the light and air, wrap themselves round pots, blocks, or anything that comes in their way, or even bind themselves together in bundles. If *Phalænopsis* are grown in pots—and we know that noble specimens are so grown—the compost used should consist of the best fibrous peat obtainable, carefully broken into lumps the size of pigeons' eggs,

or larger, and mixed with an equal quantity of crocks and fresh living Sphagnum. The pots themselves should be thoroughly clean, and may be filled four-fifths of their height with fresh crocks well washed, placing a layer of small ones on the top, and a layer of good tough Moss above that, to prevent the smaller particles of the compost from washing down and choking the drainage below. Elevate the collar of the plant well above the rim of the pot, and gently imbed the lower roots into the above compost, placing a layer of freshly-picked Moss over the whole, so as to form a rounded cone with the plant at its apex. Plants potted in this manner rarely fail to grow well, as the air has free access to the roots; and, unless this is the case, they soon go wrong, while it is almost impossible for them to be injured by any undue excess of water, as there is every facility for any superfluity of moisture to escape. The secret of Orchid-growing is

genial humidity in the atmosphere, small pots well drained, fresh living Sphagnum on the surface of the compost, and an abundant supply of tepid water, and a regular temperature when making their growth. Some of the finest specimens of *Phalænopsis* in this country are grown in pots. A superb example of *P. Schilleriana* in the collection of Mr. Milne, Yewfield House, Arbroath, is growing in a great tub, and bears nearly 200 flowers on a single spike! Mr. Rawson, of Mill Hill House, Halifax, has some remarkable specimens of *P. amabilis* and *P. grandiflora* with ten or twelve fine leaves each, and these are grown in common square wooden baskets, suspended near the roof of an ordinary span-roof plant-stove. On one plant of *P. grandiflora* I saw eighteen flowers on the tip of a branched spike all open at the same time, and these were nearly 4 inches across, and of good substance. It is seldom one sees nine fully-expanded flowers on each side of the tip end of a single spike, as above described; although we occasionally come across a plant bearing fifty or sixty flowers open at once on several great branched spikes. Mr. Turner, of Leicester, grows his noble plants of *Phalænopsis* on semicircular rafts made of teak, and surfaced with fresh Sphagnum only; and when I saw them, some months ago, they were perfect in health and vigour. Messrs. Veitch & Sons, of Chelsea, have a noble plant of *P. Schilleriana* growing on a teak-wood raft, partially plunged in a pot of fresh open compost, as above described. This specimen has ten or more fine speckled leaves in that state of fresh vigorous health so pleasing to the true plant-grower, and it is now bearing a noble spike of nearly a hundred flowers. I mention these diverse methods of treatment in order to show that there are several ways of growing *Phalænopsis* in perfection. They grow best, as a

Trichomanes reniforme.

rule, in a warm, sheltered corner, not far from the glass; and the beginner who would be successful, should try them in different positions in his house until he is perfectly satisfied as to the position in which they do best. Fortunately, some species of *Phalænopsis* have been imported in quantity, and in excellent condition; their price is, therefore, now moderate. Imported plants generally come on long blocks, and, occasionally, a part of the branch on which they grew in their native habitats is lopped off and nailed to the side of the case with the plant *in situ*. If these plants arrive during dull weather or in the autumn, it is best not to disturb them until the following spring, when they may be removed, and either placed on other blocks or potted as above recommended. When well bloomed, the plants are very ornamental from a decorative point of view, or for exhibition purposes; while their waxy flowers are invaluable for cutting, either for bouquets, vase decoration, dinner-table ornaments, or for arranging along with fresh green Ferns or other foliage in ladies' hair, especially as they last in perfection for a considerable time after being cut. The following descriptive list comprises all the species at present introduced to our gardens:—

P. amabilis.—This is generally known as “the Queen of Orchids,” it has dark green foliage tinted with purple beneath, and its branched flower-spikes are borne very freely, its individual blooms lasting a month, or even longer, in perfection. The flowers vary from 2½ to 3½ inches across, and are of pearly whiteness, except the lateral or side lobes of the lip, which are streaked with rosy-crimson. Good specimens of this plant have from eight to fourteen leaves, and bear spikes from 2 to 4 feet long. When well grown it is one of the best of *Phalænopsids*, and its snowy blossoms are useful for cutting. It is a native of Manilla.

P. amethystina (P. Wightii).—This pretty little plant is rather rare in collections, and is not so showy as some of the other species; still it is well worth growing, and lasts a long time in bloom. It has deep green oblong foliage, with wavy margins, and bears short-branched spikes, which vary from 3 to 12 inches in length. The flowers are little more than half-an-inch across, the sepals and petals being white, dotted with rosy-purple at the base. The lip is of a deep amethyst-purple tint, tipped with white, and having two slender horns at its base. It is a native of the Sunda Isles, and has flowered with Dr. Ainsworth, Mr. C. Stead, and Mr. Day, of Tottenham.

P. cornu-cervi (Stag's-horn Phalænopsid).—This is a peculiar plant, somewhat resembling *P. Luddemanniana* in habit, but bearing shorter flattened spikes of yellow flowers, blotched transversely with brown. The flattened flower-spike is a peculiar feature; hence its specific name. It grows well treated like its congeners, and is worth cultivation for the sake of variety. It was discovered by Mr. Lobb, and is known as *Polychilos cornu-cervi*. Native of Moulmein.

P. grandiflora.—This is now one of the commonest of all the species, and may be bought for shillings where guineas were formerly demanded for it. It is one of the best and most profuse flowering of *Phalænopsis*, and grows well either on a block or in a pot near the light. There are numerous varieties of it in cultivation, all more or less distinct, the Bornean plants being for the most part the best. The sepals and petals, like those of *P. amabilis*, are pure white, the lateral lobes of the lip being tinted with golden-yellow; and, in the best forms, the tails at the tip of the lip are yellow, spotted with crimson. The best variety is known as *P. grandiflora aurea*, or *Ruckerii*, and has the side lobes of the lip deeply stained with golden-yellow, while the petals are very broad and more rounded than is generally the case. The varieties of this grand Orchid not only vary in the size of their flowers, but also in the length and breadth of their light green foliage. Mr. Williams, of Holloway, has a fine plant of it, with ten or twelve fine leaves borne on a stem nearly 6 inches high, and this is now producing two very strong spikes. Mr. C. Stead, of Baildon, near Leeds, has a fine plant of the narrow-leaved variety, with fourteen or fifteen leaves 10 to 15 inches long, and only 2 to 2½ inches broad. This is a Bornean plant, and flowers very freely, bearing large flowers of good substance. Native of Borneo and Java.

P. intermedia (P. Lobbii).—This plant is very beautiful, having white flowers shaded with rose, about the size of those borne by a small-flowered *P. Schilleriana*, the lip being of a still deeper rosy-tint. In habit it resembles its allies, and it also does well under the same treatment. It is a native of Manilla. There is a fine variety of this species known as *P. intermedia Portei*, a native of the Philippine Islands, only a solitary plant having been found by M. Porte, its discoverer. Its foliage is light green above, and purple below; being 8 or 10 inches in length. It is supposed to be a natural hybrid, and is one of the rarest of all known Orchids. The flowers are 2 inches across; sepals and petals white, suffused with rose; the lip being of a dark rosy-purple tint.

P. Lowii.—This is a pretty little species that grows best on a block suspended near the light. It bears eight to ten-flowered

spikes, about a foot high; the flowers themselves being of a soft rosy-lilac tint. The front of the column is curiously prolonged, like the beak of a bird. In its native habitat it grows on limestone, fully exposed to the sun, and loses its foliage every year during the hot and dry season; but, here at home, the plant frequently retains its foliage through the winter months. Its leaves are about an inch wide, and 2 or 3 inches long, of a dark green colour, speckled with purple. Mr. Bockett, The Firs, Muswell Hill, has a fine plant of this species, with leaves nearly 4 inches long and 2 inches wide; and it also does well in Lord Londesborough's collection. It should be kept rather dry during winter, and fully exposed to the light, or it is apt to lose its leaves. It comes from Moulmein.

P. Luddemanniana.—This is one of the most beautiful and distinct of all the *Phalænopsids*; having leaves of a bright-shining green, and about 6 or 8 inches long. The flower spikes are very variable in length, but generally about 18 inches or 2 feet; the flowers being of a soft amethyst-purple tint—in the best varieties blotched with brown—the narrow lip being set with a row of white hairs down its centre. There is a poor variety of this plant, having pale yellow flowers, barred with brown, called *P. Luddemanniana ochracea*, but the amethyst-tinted varieties are best. This plant grows very freely in a pot, and very often produces young plants on its flower-stems. There is a fine plant of the best variety in Mr. W. Hadwen's collection at Fairfield, near Manchester, which seldom fails to bear two or three young plants every year. Philippine Isles.

P. Parishii.—This is the smallest, and, at the same time, one of the prettiest of all the *Phalænopsids*. Its leaves are about 2 inches long and of a grey or glaucous tint. The small violet and white flowers are borne five or seven together on spikes about the same length as the leaves. Although not so showy as the larger-flowered kinds, it is, nevertheless, well worth cultivation. Native of Burmah.

P. rosea (P. equestris).—This is a pretty plant, similar in habit to the last named, and worth growing in every collection for its free-blooming qualities. Its flower-spikes are of a deep purple colour, and keep on producing flowers for months in succession. The flowers are of a soft rosy-lilac colour, scarcely more than half-an-inch across, but the want of size is made up for by the numbers produced. There is a good plant in Mr. B. S. Williams's collection, and another at Kew. It is a free grower, and comes from Manilla.

P. Schilleriana.—One of the best of all Orchids with variegated foliage, bearing great branching spikes 3 or 4 feet high, with from 100 to 200 rosy flowers fully expanded at the same time. Few of the other species rival this when well grown, and the plant is hardier in constitution than any of the others at present introduced. The leaves are of a deep green colour, variously mottled and marbled with silvery-grey. The sepals and petals are of a rosy-lilac colour, the lip being tinted with rose and spotted at the base with warm crimson-brown. It does best in a pot, although small plants luxuriate well enough on flat blocks. It is a native of Manilla.

P. Sumatrana.—The foliage of this plant resembles that of *P. Luddemanniana*, and it grows well under the same treatment as recommended for the last-named species. The flowers are white, barred with pale rosy-crimson, and about 2 or 2½ inches across. It flowered with J. Day, Esq., of Tottenham, in 1865, but is still extremely rare in collections, although well worth growing. As implied by its specific name, it comes from the island of Sumatra.—*Gardener.*

Philesia buxifolia.—This pretty evergreen shrubby plant is a native of South America, and is hardy in the warmest parts of England and Ireland; it, however, succeeds best when treated as a cool greenhouse plant. Its leaves are short and stiff, not unlike those of Box, and it produces a profusion of bright rosy-red flowers, the petals of which are thick and fleshy, and not unlike those of *Lapageria rosea*, but much smaller. Indeed, the relationship between the two genera is so close, that Messrs. Veitch raised a hybrid between the *Philesia* and the *Lapageria*, which they called *Philageria*. In this case the *Philesia* was the male and the *Lapageria* the female parent. The finest specimen of the *Philesia* with which I am acquainted is that in Dalvey Gardens, Forres. It is in a 14-in. pot, and is fully 3 feet high and 3½ feet through, a dense mass of erect shoots. It is grown in an airy greenhouse, on a central bench near the glass. Mr. Berry, the gardener at Dalvey, finds that it does not bloom well unless it is considerably pot-bound; therefore, he only re-pots it once in four or five years, using in the operation a compost consisting of peat and loam. It is now three years since the plant in question was last shifted, and the pot is as full of roots as it well can be; indeed, they are even over-running the surface. Its growths are remarkably healthy and strong, many thick-branched shoots, fully 3 feet long, being annually produced. Whilst growing, this plant requires abundance of water, and sometimes a little weak manure-water; but in winter it should only be kept moderately moist.—W. F.

BROAD-LEAVED LACHENALIA.

(LACHENALIA PENDULA.)

THIS is an old plant, but it is one which is rarely met with in collections of bulbous plants. In habit, it is quite distinct from its congeners, having very broad and massive leaves, of a fresh green colour, and not blotched or spotted, as is the case with many of the others. This species was lost sight of for some years, until it turned up at one of the meetings of the Royal Horticultural Society in November last, when it was exhibited in good condition by Mr. Chambers, of the Westlake Nurseries, Spring Grove, Isleworth. Our figure, made from a sketch taken at the time, shows the habit of the plant extremely well. The stout spikes are about a foot high, as thick as a swan's quill, slightly stained, or blotched, with crimson, the flowers being of an orange tint, tipped with green and purple. The segments of the perianth, as shown in our illustration,

Lachenalia pendula.

are all about the same length. It succeeds well, like the other species of the genus, in a cool greenhouse.

Reineckia carnea variegata.—This is a pretty little plant, with green and white variegated leaves that have a somewhat Grassy appearance, and are thickly produced on prostrate or pendent Dracæna-like stems. It produces annually a profusion of showy rosy flowers, and it is easily cultivated as a pot plant in a greenhouse. It grows well in peaty soil, or in loam mixed with leaf-mould, but in this respect it is not particular. Plants of this are useful for growing with Ferns in shady corners, where they thrive almost as well as if exposed to light. They are more suitable for growing in pots than in baskets, because when alone they flourish best. Their slender shoots or stems droop down over the sides of the pots in which they are placed so as almost to entirely hide them. This plant is readily increased by means of cuttings struck in a little heat, or from layers. It is very suitable for windows, as it is tenacious of life, and grows well in a low temperature, and in a shady place.—F. W.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

White Forced Lilacs.—What is the name of the White Lilac which forces so well, and when ought it to be potted for winter-flowering?—SYRINGA. [The White Lilac, seen in our flower markets in winter and spring, is the common purple Lilac forced in darkness, a system of culture largely practised in France. The plants should be potted (see p. 181) in the October previous to that in which they are to be forced.—Ed.]

Scarborough Lilies.—A friend has sent me some bulbs under this name. What are they?—G. S. [Your bulbs are, doubtless, those of *Vallota purpurea*, which, though a Cape plant, is often called the Scarborough Lily. It succeeds perfectly in a greenhouse, and, if treated liberally in summer, especially as regards water, it will flower freely in autumn.—Ed.]

Camellia Cuttings.—When should these be struck? and what is the best method of striking them?—T. G. H., Alston. [August is the best time for striking cuttings of Camellias. Select good firm shoots, cut them about 6 inches in length, and insert them in pots filled with peat and silver sand in equal proportions, and surfaced with the latter. Place the pots containing the cuttings under a hand-glass or frame in a gently-heated pit. When rooted, remove them to the side shelves, but do not disturb them at the root till next spring, when, if they are in good condition, they may be potted singly in small 9-sized pots.—Ed.]

THE FRUIT GARDEN.

RASPBERRY CULTURE.

THE main question at issue between Mr. Taylor (see p. 168) and myself seems to be this: What ought to be the duration of Raspberry plantations? Mr. Taylor says, in effect, do not make a new plantation so long as the old one bears well, and he takes his stand upon a plantation in his mind's eye, from twenty to thirty years old, thereby suggesting that Raspberries ought, at least, to last that length of time. My advice is, do not delay making the new plantation till the old one fails; it is obvious, however, that, whether the period of duration shall be six, ten, or more years, must depend, in some measure, upon local circumstances, always, carefully bearing in mind that it is not easy to do wrong by transplanting too frequently, whilst a mistake in the opposite direction would certainly, for a time, curtail the supply. In the ordinary course of cultivation, I would not take cuttings or save seeds from a sickly plant, and, on the same principle, I would not willingly plant suckers from an exhausted Raspberry plantation. Raspberries are indigenous to Britain, and I have seen acres of them growing wild in woods, but, as might have been expected, I always found the strongest canes and the finest fruit on the outskirts of the thicket where the roots had access to fresh soil, and the canes had more breathing-room. I consider the system of culture that permits them to remain from twenty to thirty years in one place tied up in a most unnatural manner in bundles is but one degree removed from their wild state in their native thickets. There are, I know, in a few spots, deep soils of alluvial origin, where the Raspberry will continue in bearing condition for many years; but even there I am far from admitting that a more frequent removal would not be beneficial. These, however, are exceptional cases, and cannot be fairly considered as applicable to the majority of gardens. Mr. Taylor, in his closing remarks (to use his own words), offers me a nut to crack. In effect, he says, that some years ago he assisted in planting several rows of Raspberries; that for the first two or three years they grew immensely, producing canes like Bamboos, and with eyes a foot apart, and then he adds—Strange to say, they produced very little fruit, and asks what was the reason? I may be allowed to ask, does not this description of early luxuriance tend to confute Mr. Taylor's exhaustion theory started in the early part of his communication. The solution to the problem just propounded lies in a nut-shell; it is, I think, a clear case of "plethora," caused by over-feeding; probably, the plants were planted in trenches full of manure; at any rate, too much food of a stimulating character had been placed in contact with the roots. I have already stated that, in my opinion the land should be deeply trenched for Raspberries, burying the manure at the same time. When bearing commences, and the roots extend, they will, in that case, find food ready prepared for them. Plant without manure, but, if the soil is very inferior, a compost, consisting of burnt earth, lime-rubbish, and loam may be advantageously used, a spadeful or so being put into each hole just to give the roots a start. Above all things, at the commencement of dry weather, do not forget to mulch; the water-cart will not then be so often required; in fact, I seldom water; and, with a soil deeply cultivated and mulched, there is not much necessity for it in nine seasons out of ten. As to frost killing Raspberries, the destruction is not always fairly due to the severity of the weather; there are predisposing causes, induced, in some instances at least, by the system of culture pursued. In the case of over-luxuriance, when I thin the young growths in summer, I leave the weakest and cut away the gross shoots, on the same principle that we pinch a gross shoot in a fruit tree, and, in the winter-pruning, do not cut the canes back to the orthodox 4 feet, but leave them longer, say up to 5 feet, or longer if necessary. If they are trained to wires, espalier-fashion, as I have previously recommended, and trained diagonally in an oblique direction, it will have a tendency to break the back eyes, and the best way of moderating growth is to leave the canes a good length and let them bear well. Suckers not required for new plantations should not be allowed to grow; and, in forking over the ground, they should be cut off without injury to the roots.

E. HOBDAV.

THE DIFFERENT RACES OF STRAWBERRIES.

IN a recent number of THE GARDEN we called attention to the second edition of the treatise "Le Fraisier," which the Comte de Lambertye has written on the history and culture of this fruit, to which much more attention has been paid by continental cultivators than by our own fruit-growers. The following extract from the first section of M. Lambertye's work, which describes the geographical distribution of the original species, will perhaps be interesting to some of our readers. After remarking that the French name of the Strawberry-plant (Fraisier) is derived from the Latin word fragrans, in allusion to the sweet smell of the fruit, the Comte proceeds as follows:—According to Jacques Gay—a learned botanist, who made a very attentive study of these plants—Strawberries may be classed under eight distinct species, which are thus distributed:—Three European—*F. vesca*, Lin.; *F. elatior*, Ehrh.; *F. collina*, Schrb. Three American—*F. chilensis*, Duch.; *F. Virginiana*, Mill., Ehrh.; *F. Grayana*, Elisa Vilm. Two Asiatic—*F. Daltoniana*, Gay; and *F. Nilgerrensis*, the two last being natives of northern India.

Descriptions of the Species.

EUROPEAN KINDS.

1. *FRAGARIA VESCA*, Lin. (The Wild Strawberry).—This is the most common species of all, and is found in the mountainous parts of Europe, as high as the region of the Pines. In the Alps, it ripens its fruit in August, at an elevation of over 5,000 feet. It is found as far north as Iceland and Lapland, and occasionally occurs in Asia and America. Of this species the following are the chief varieties:—(1) *F. semperflorens*, which in France is known under the name of des Quatre-saisons, or de tous les mois. (2) The very curious variety, *F. muricata*, or the Plymouth Strawberry, the petals of which present the strange anomalies of being five-lobed, and green instead of white, while the stamens are transformed into small leaves. The seeds on the fruit are also transformed into leaf-buds. (3) *F. monophylla*. (4) *F. efflagellis*. This variety does not produce runners. (5) *F. multiplex*, with double flowers; and (6) *F. hortensis*.

2. *F. ELATIOR*.—Known in England as the Hautboy, and found in certain localities, here and there, throughout Central Europe. It is generally dioecious, from a partial abortion of the flowers, so that it is often found sterile in a wild state, and sometimes, even when grown in gardens. The chief original varieties of this species, which is known in France under the name of Capron, are (1) Capron royal, of which every plant is fertile, and (2) Capron framboise or Capron noir. All the Caprons, or Hautboys, have a peculiar flavour, very distinct from that of all other kinds of Strawberry.

3. *F. COLLINA*, Schreb.—This species is very widely distributed over Central Europe, and extends partially into Asia. A peculiarity of this kind is, that the calyx covers the fruit in the form of a star, hence its French name of Fraise étoilée. Its principal varieties are (1) *F. pentaphylla* or *F. heterophylla*, and (2) *F. Hagenbachiana*, the variety in cultivation. This is known as the Bargemon Strawberry, and is the famous Majaufe de Provence of Duchesne. Jacques Gay considers it a hybrid between *F. vesca* and *F. collina*.

AMERICAN KINDS.

4. *FRAGARIA CHILENSIS*, Duch. (the Chili Strawberry).—This plant, which is a native of Chili, and probably, also, of California, is only found on the Pacific shores of America. It is distinguished from all other species by the greater size of its leaves, flowers, and fruit. It was introduced into France in the year 1712. The flowers are liable to become sterile from abortion. It does not succeed very well in the neighbourhood of Paris; but is grown on a large scale, and with much success, in the commune of Plougastel, near Brest. Its original varieties are—(1) *F. Ananassa* (the cultivated type, *F. grandiflora*); and (2) *F. de la Caroline*. This Chili Strawberry and its variety, *F. Ananassa*, are the origin of most of the large-fruited Strawberries which have been obtained by hybridisers.

5. *F. VIRGINIANA*.—Mill. Ehrh. The Old scarlet or Original scarlet of the English. This kind is named in the catalogue of Jean Robin (botanist to Louis XIII.), so far back as 1624.

Either from natural hybridisation or from artificial crossing with the Chili Strawberry, it has been the parent of many varieties.

6. *F. GRAYANA*, Elisa Vilmorin (*F. Asa-Gray*).—A North American species, closely allied to *F. Virginiana*. A variety of it (*F. lucida*) has shining leaves.

ASIATIC KINDS.

7. *F. DALTONIANA*, Gay, and 8. *F. NILGERRENSIS*, at present are only to be found in Europe in the condition of dried specimens in herbariums.

From the foregoing original species, numerous varieties have been raised in gardens. A list of twenty-four of the best kinds, classed according to their distinguishing qualities, is given by M. de Lambertye, as follows:—(1) Varieties, which combine all the excellencies of fine flavour, fertility, beauty, and hardiness—Avenir, Gabrielle, Marguerite, Marquise de Latour-Maubourg, Sir Harry, Souvenir de Kieff, and Wonderful. (2) Varieties, which produce the most exquisitely-flavoured fruit—Avenir, Belle Lyonnaise, Carolina superba, Doctor Hogg, Gabriel, Madame Nicaise, Marquise de Latour-Maubourg, Quatre-Saisons, Savoureuse, Sir Harry, Souvenir de Kieff, and Wonderful. (3) Varieties which produce the largest fruit—Anna de Rothschild, Belle de Sceaux, Doctor Hogg, Marguerite, Napoleon III., Muscadin de Liège, Sir Joseph Paxton, Sir Harry, and Victoria (Trollope). (4) Varieties which bear carriage best, and which from the firm nature of the fruit are most suitable for making preserves—Avenir, Belle Lyonnaise, Bonté de Saint Julien, Carolina superba, Madame Nicaise, Marquise de Latour-Maubourg, Sir Joseph Paxton, Souvenir de Kieff, and White Pine-Apple. (5) The latest-ripening varieties—Anna de Rothschild, Bonté de Saint-Julien, Doctor Hogg, Napoleon III., and Wonderful.

Points to be Observed in Judging Orchards.—The following is the scale of points adopted by the committee of the Michigan Pomological Society, for the purpose of facilitating the examination of the large number of orchards in different parts of the State, entered for the premiums offered by the society.

	Apples.	Pears.	Peaches.	Plums.	Grapes.	Small fruit.	Nurseries.
Soil	15	20	10	10	15	20	52
Protection	5	10	25	10	15	10	10
Market	5	10	10	15	10	20	5
Variety and arrangement	15	10	10	10	10	15	25
Culture	10	10	10	10	10	5	15
Pruning	10	10	10	5	15	15	15
Health, and absence of insects ...	20	20	20	20	20	20	20
Fruitfulness	5	5	5	5	5	5	—

Any orchards receiving all the numbers as high as those given, would, of course, be regarded as perfect, and various lower grades of merit would be indicated by smaller numbers. This scale of points would vary somewhat from the above in other States or localities, when the different qualities or departments in management become more or less prominent or important, but such a table would be of great use to any committee about to make similar examinations.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Fruits admitted by the French Pomological Congress in 1873.—Cherry (of the Black Heart class), Pourprée Hâtive. Very large; stalk, long and slender. A productive, very early sort. Raspberry, Surpasse Fastolf—A commendable variety, producing two crops of fruit. Pear—Beurré de Nivelles—An excellent late variety, raised by M. Parmentier. Pear, Jules d'Airolles—A seedling, from M. Léon Leclerc, of Laval. Flesh, delicate, juicy, melting, tender. Ripens in December. Apple, Bouque preuve—A late-flowering variety, largely cultivated around Marseilles. Apple, Rose de Provence—Another good Apple, widely distributed in the south. Grape, Tschouch Safra Usum—Handsome bunches, with large white berries. Introduced from Turkey.

Receipt for Making a Mixture for Painting Vines, Peaches, and Figs.—Take 1 lb. of soft-soap or Gishurst Compound to every gallon of water, and let the water be boiling hot, so as to thoroughly dissolve the soap. Add $\frac{1}{2}$ lb. of flowers of sulphur to every gallon of water, and as much quick lime as will bring the mixture to the consistence of thick paint. Mix all well together when the water is hot, and, when the mixture gets cold, add a gallon of strong tobacco-liquor to it. When painting this mixture on Peach trees, it is safest to reduce its strength by adding a little more water, and some clay as well, so as to take off the whiteness of the lime, which is an eyesore to some when looking at the trees. Before painting this mixture on Vines and Figs, remove all the rough bark, and, when the mixture is dry, it will be seen where any part or crevice in the wood has been missed. Where such occurs, apply the mixture again.—W. TILLERY, Welbeck.

WORK FOR THE WEEK.

Conservatories.

THE materials for keeping up an effective display in conservatories will now have become more plentiful than during winter, and one of the most important considerations is, to see that portions of such things as will bear retarding without injury are at once placed under conditions to ensure their being made available later in the season. Where, indeed, anything like a continuous supply of blooming plants is required, it is quite necessary to have at command a house so placed that the sun will have little influence upon it, except for an hour or two morning and evening. A lean-to with a north aspect is best. Many imagine that such houses are only required by those who retard plants for purposes of exhibition; this is a mistake. By selecting a portion of the stock of Camellias, Azaleas, Epacrises, Geraniums, Cinerarias, Cyclamens—in fact, any of the numerous greenhouse plants that are used for conservatory decoration, the blooming season may be prolonged to almost double its usual length, especially if judgment is used in selecting varieties that are naturally late in flowering. Camellias—*candidissima*, fine white; *Bealii*, red; *Avinia Maggi*, striped;—Azaleas—*Brilliant* and *Juliana*, both red; *Extrani* and *coronata*, both bright rose; *Gledstanesii formosa*, white striped;—Epacrises—*Eclipse*, *grandiflora*, *rubra*, and *miniata* splendens. These, and others, which the careful observer cannot fail to note, can be retarded without injury, so as to come in at a time when they will be found of great use. And it is not only during spring that such a house will be found of the greatest value; it will also be an excellent place in which to harden the stock of Ghent Azaleas, double-flowering Plums, Lilacs, Spiræas, &c., that have been forced, and which frequently, from want of a suitable place, are subjected to treatment ill calculated to render them of use the following season. Later in the season, too, it will suit Camellias well that have set their bloom, and which, from want of proper accommodation, are turned out of doors; still further on in the season, late-flowering chrysanthemums may be kept safely in such a house until the middle of January, at which time they will be found most useful. Large Camellias, which have got leggy from want of judicious pruning when young, or through overcrowding, may be improved in the following manner:—Take, at once, a couple of healthy young plants, in 6-inch pots of any approved kind, place these on the surface of the ball of the plant to be operated upon; then inarch the heads of each of the young plants as low down as they can be put on the opposite sides of the large plant. These will become firmly united during the summer, when they may be severed from their original stems; and, in the following season, before growth commences, the head of the stock may be cut away just above where the young plants have been inarched, when they will commence to grow apace, and, in a little time, make handsome plants. Moveable shading, of thin material, should be got ready, as bright sunshine on a March day makes short work of many things that flower. Pinch out the points of a portion of the stock of Pelargoniums. These will be useful in July, after the early ones are over. Start another batch of Achimenes, Gloxinias, and Tydæas for summer decoration. See that Lilies, breaking through the soil, are not left where they have an insufficiency of light; otherwise they make weak growth, which no care afterwards will put right.

Orchids.

Last month and the present one constitute the recognised season for re-potting Orchids; it is, however, almost impossible to adhere strictly to this rule, other departments requiring so much attention at this busy time of the year; Orchid-potting and overhauling are, therefore, for the most part, done in winter. For such as are quite dormant, winter-potting is quite applicable, provided the plants are kept dry after the operation until required to start into growth. *Cattleyas*, *Cattleyas*, *Angræcums*, &c., also *Oncidiums* on blocks, and others, may be safely treated in this way; whereas terrestrial orchids, such as *Phajus*, *Miltonias*, *Calanthes*, *Sobralias*, *Bletias*, &c., should be shifted just as they begin to grow. Now, when all orchids are in a growing state, a moist atmosphere and a gradually-increasing temperature should be maintained. Sprinkle water on the paths, walls, and stages, and keep a supply in the evaporating troughs. Syringe the plants daily, in time to permit the foliage to get dry before nightfall. Take care that plants on blocks are not put up immediately over pot-plants, as the drip from them injures the leaves of the latter. See to the eradication of insects, such as green-fly, thrips, scale, &c., by fumigating or washing with water in which some soft-soap and Gishurst compound have been mixed. Set traps for cockroaches, in the form of jam-dishes with some scale and water in them, be set amongst the plants, so that, when these pests fall into them, they may get drowned. Phosphorus paste also kills them. Ants may be trapped by means of sponges steeped

in sugar and water, or in other sweet substances, placed here and there amongst the pots. Ants congregate on them in thousands, when they may be destroyed by plunging the sponge into boiling water. After the water cools, wring out the sponges, re-steep them in the sweet matter, and place them again amongst the pots. Fresh bones form excellent traps for ants, which should be thrown into boiling water every morning, as in the case of the sponges. Trap wire-worms with cut Potatoes, and woodlice by means of little pots containing dry Moss.

Indoor Fruit Department.

Pine-apples that have not been already shifted should now be re-potted or transplanted into beds. Whether grown in pots or planted out in frames or pits, the heating material should be entirely or partially renewed. If fire heat is used for bottom-heat, greater care than would otherwise be necessary must be exercised in watering, as the bottom part of the soil frequently becomes dry, when that on the surface is apparently quite moist. Now that the store-plants are beginning to push, the atmosphere, as well as the soil in which they grow, must be kept moist. Ventilate a little during the heat of the day, and cover the frames with mats at night. Fig-trees in pots will be swelling their fruits; therefore, some liquid-manure given to them two or three times a week will be of great importance to the crop; mulchings of manure answer the same purpose. Those on walls or on front trellises should be started in succession, by closing up the house, syringing twice a day, and stopping the shoots at the third and fourth joints. Pot-Vines, if liberally fed, will produce good crops; and, as they are frequently thrown away after bearing, as many bunches may be left on them as they can properly mature and colour. Thin Grapes in general, stop and rub off young shoots, encourage good foliage, and maintain a brisk moist temperature except in late Vineries. All old Grapes yet on Vines should now be taken off and preserved. The dampness of the winter has been rather productive of mouldiness amongst those kept in water-bottles. Regulate the growth of Peaches and Nectarines, and disbud and thin the shoots as necessary; thin out, also, all the smallest fruits, and syringe morning and evening. Keep Cherry-houses well aired. Introduce successions of Strawberry plants, and place them on top shelves in Vineries or Peach-houses, or arrange them near the glass in pits or frames, when a little bottom-heat, given by fermenting material, is very beneficial to them. To plants whose fruit is colouring, little or no water should be given, as it deteriorates the flavour. Sow the main crop of Melons and Cucumbers, and pot off those already up; such as are large enough may be transplanted permanently. Beds for the reception of the seedlings should be formed completely of fresh soil, for from the plants raised now the greatest amount of fruit is commonly obtained.

Hardy Fruit Trees.

Pruning and planting should now be completed, and any training yet undone should also be finished. Espaliers requiring new stakes should have them supplied at once. Any trees loosened from walls for the purpose of "pointing" the latter *i.e.*, filling up holes between the bricks caused by repeated nailing, should be fastened to them again, for the buds are now swelling fast. Fruit trees, however, are not nearly so forward as it was anticipated some two months ago they would be. If not already done, however, no time should now be lost in affording protection to Apricots, Peaches, and Plums on walls. If Strawberry plantations require increasing they should now receive attention. Old plantations of them, if not already done, should be mulched, which will both feed the plants and keep the fruit clean.

Roses.

Roses are now in so forward a state as to almost necessitate immediate pruning in order to have dormant eyes to prune back to. The present time is considered, we believe, by amateurs early for the operation; but, from considerable experience, we think pruning should be done earlier in the season than it is in general. Thin the shoots well out, leaving no wood in the head that is not healthy and fairly vigorous. Study the individual habits of the Roses; the catalogue descriptions of vigorous, robust, and moderate being in some sense guides. For instance, *Maréchal Vaillant*, a vigorous kind, does not bloom if cut in close. Its shoots require to be left at least one foot to one and a half foot in length. Robust Roses, as *Madame Vidot* or *Baroness Rothschild*, with short stumpy wood, should be pruned to a prominent bold eye—the best on the shoot, high or low. The small wood of these sorts never yields blooms worth having, and must be cut clean out. Moderate Roses, as *Mdlle. Bonnaire* or *Xavier Olibo*, need close pruning. They may be cut in almost to the old wood; quite so, when the shoots are weak. The eye to which the shoot is pruned should, if possible, look outwards. If this rule is followed, a hollow head will be formed, allowing air to circulate well amongst

the foliage and flowers. Prune, if possible, after a day's drying weather, as, if the ground is in good order, Roses do not bleed badly. Choose, likewise, fine weather to dig the ground, turning in some manure, unless this has been already done, when a mulching of some short horse-dung (road-droppings, fermented by having been in a heap, are good for them) may be applied early in April. Make good all vacancies in borders where the kinds to be planted are Hybrid Perpetuals, Noisettes, and standards of the Teas, and reserve places for dwarfs of Tea Roses, which are better planted from pots in May. In the forcing-houses a few kinds started in November will be just opening. *Souvenir d'un Ami*, *Madame Falcot*, and the white Hybrid Perpetual *Marquise de Montemart* are amongst the first. Where plants are just breaking, syringe twice a day, which will also supply almost sufficient moisture to the plants; 55° to 60° is a good day temperature, which may fall to about 50° at night. All pot-Roses should now be pruned, as after May, grown under glass, they do not compare favourably with the early flowers from out of doors. It is well, therefore, to get all pot-Roses over by the end of that month. Pot-Roses should always be pruned some days before being started, however slowly, into growth.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY,

MARCH 4.

THIS exhibition consisted almost wholly of nurserymen's productions, foremost amongst which stood those of Messrs. Veitch, who deserve credit for the liberal way in which they show their plants on such occasions. The proceedings of the Fruit Committee were reduced to a minimum, two dishes of Apples, and six pots of French Beans being all the exhibits staged. The attendance of fellows and their friends was anything but numerous.

Miscellaneous Plants.—Messrs. Veitch staged a basketful of fine hardy rosy-purple-flowered *Rhododendron*, named *Early Gem*, a most profuse bloomer, and its deep glossy foliage contrasted well with the flowers. The specimens staged were just taken up from the open ground, and they certainly deserve a prominent position in a collection of early spring-flowering shrubs. The Roses in pots staged by the same firm, though small, were admirable. The pots in which they were grown were neatly covered with fresh Moss, which contributed much to their effective appearance. Among the Tea-scented kinds we noticed *Coquette de Lyon*, pale sulphur; *Madame Falcot*, salmon; *Marcelin Roda*, creamy-white; and *Madame Willermoz*. The hybrid perpetuals were most profusely flowered, and included *La France*, pale silvery-rose; *Princess Mary of Cambridge*, rosy-pink, fine in bud; *Paul Neron*, crimson, with silvery backs to its petals; *Camille Bernardin*, rich crimson; *Marquise de Castellane*, rosy-salmon; *Felix Genero*, deep rose, densely imbricate; *Fisher Holmes*, deep velvety-crimson; *Madame Victor Verdier*, with revolute petals, and fine vivid crimson in colour; *Richard Wallace*, deep rosy-crimson; and *Madame Marie Rady*, a finely-formed flower of a deep rose. Such plants as these are amongst the most useful of all plants for general decorative purposes, in pots or for culture. The Japanese Privet, *Ligustrum japonicum*, was shown by Messrs. Veitch, contrasted with a much better variety, *L. japonicum lucidum*. The former has a dull and somewhat rusty appearance; while the latter has deep glossy foliage, as bright, but much larger than that of the broad-leaved Myrtle. One of the most interesting features in the show was a collection of *Clematis*, staged by Messrs. Veitch. These plants bear great white, lilac, or purple, star-shaped flowers, very easily grown. Miss Bateman, a large-flowered waxy-petalled variety, and a most profuse bloomer; *Albert Victor*, lilac-purple; *Lady Londesborough*, very large and fine soft lilac; *Lucy Lemoine*, fine white semi-double, with lance-shaped sharply-pointed segments. This is likely to become a favourite. One of the most curious points in both the specimens of this plant is the production of variegated foliage and bracts among the foliage in the whorl, immediately below the flowers. Messrs. E. G. Henderson & Sons, of St. John's Wood, staged a group of *Cyclamens*, and a basket containing twenty-four well-bloomed plants of *Soldanella montana*. Messrs. Standish & Co., of Ascot, staged a nice group of *Spiræas*, *Lily of the Valley*, *Hyacinths*, and other spring flowers. From Messrs. Barr & Sugden came a box of *Iris reticulata*—one of the finest of the early-blooming kinds. It has sharp angular glaucous foliage, and bears solitary dark purple flowers marked with golden-yellow. A nice variegated form of *Imantophyllum miniatum* was staged by Mr. E. J. Barker, Exotic Nursery, Little Hampton, under the name of *I. Barkerii*; the bright green foliage of the normal form is, in this instance, heavily striped with creamy-yellow; the plant staged was not well grown, and there is little doubt that a well-grown specimen would obtain a first-class award. Mr. W. Bull exhibited a nice plant of *Encholirion corallinum* with arched glaucous foliage covered with dark irregular marks, and bearing a crimson flower-spike with golden flower-buds. A cut specimen of a *Medinilla*, supposed to be new and named *M. amabilis*; it is similar in habit to *M. magnifica*, but taller, and bears large erect spikes of rosy-lilac flowers, without the large bracts so characteristic of the last-named species.

Orchids.—A fine bank of these was set up by Messrs. Veitch, including the following rare species:—*Angræcum citratum*, a dwarf

species, resembling a *Phalænopsis* in general habit, and bearing long spikes of creamy-white flowers, each furnished with a curious bent spur; *Dendrobium Boxallii*, nearly resembling *D. crystallinum* in flower, with the habit of *D. Wardianum*; it has white sepals and petals tipped with rosy-lilac, the lip having a large central blotch of yellow. In this group was a fine plant of *Dendrochilum glumaceum*, bearing fifty or sixty spikes of its graceful grass-like flowers among foliage of the freshest and healthiest description. *Epidendrum paniculatum* is a tall-growing species, bearing a large terminal panicle of flowers, not unlike bunches of the common Lilac in form and colour. A plant of *Dendrobium thyrsoiflorum* bore two fine drooping spikes of its elegant flowers. The sepals and petals are pure white, the lip being of the deepest orange-yellow colour, very much fringed around the margin. A plant of *Odontoglossum Hallii* bore five very large flowers; and several specimens of *O. Alexandræ*, *O. gloriosum*, *Ada aurantiaca*, *Lycaste cruenta*, and *Vanda suavis* made up the display. Mr. Bull staged a fine healthy plant of *Cymbidium Mastersii*, bearing a seven-flowered spike of flowers. Mr. Denning staged a plant of *Epidendrum Imperator*, bearing two spikes of crimson blossoms with a white-crested lip.

First-class Certificates were awarded to the following:—

Clematis Lucy Lemoine (Veitch), a free-flowering variety with fresh green foliage, and ample semi-double white flowers.

Rhododendron Duchess of Edinburgh, a vivid crimson-coloured variety, and a welcome addition to the already beautiful group of greenhouse species.

Epidendrum Imperator (Denning), a tall-growing species with deep green glossy foliage, and long terminal spikes of crimson flowers, having an elegantly-fringed lip. The plant grows a yard in height.

COVERING IN COVENT GARDEN MARKET.

IT is, to a certain extent, gratifying to learn that at "an extraordinary general meeting" of the Market Gardeners, Nurserymen, and Farmers' Association, lately held at the Bedford Head, Covent Garden, it was announced that his Grace the Duke of Bedford had at length determined to cover in Covent Garden Market; and a model of the proposed roofing was exhibited and taken into consideration by those assembled. Of the advisability of being thankful for small mercies there can be no doubt, especially when we reflect on the weary length of years during which the most desperate attempts were made to "get at" the late Duke of Bedford, and induce him to accede to some structural reform on his magnificent but shamefully neglected Covent Garden estate. London has every reason to be grateful to the present head of the princely House of Russell for entertaining a proposition which, if carried out, will shelter the stall keepers and their customers from the inclemency of the weather. It is, however, somewhat vexatious to learn from our contemporary, *THE GARDEN*, that the improvement contemplated will be slight indeed in comparison with what is really required. Several members of the association who met at the Bedford Head considered that the proposed covering was too low; while, by others, a 4-foot opening left on either side was held to be most objectionable. They were told that the lowness of the roof and the side openings were rendered necessary for the convenience of those who occupied the upper rooms over the central avenue of the market. So that it is to be the old, old story over again; the story of a great public want being left but half fulfilled, and of a structure which needs pulling down altogether, and re-building in accordance with modern ideas, being cobbled and patched up in order to serve the "convenience" of persons possessing ostensibly "vested" interests. Boldly and liberally re-built, Covent Garden and the surrounding piazzas might be made one of the most splendid public places in London, and, in a few years, would repay the Duke of Bedford thrice the amount per cent. that his property yields him now. Patched and cobbled up, the market will not cease to demand reform, and some day or another it will have to be reformed altogether, by being abolished as a nuisance. —*Telegraph*.

OBITUARY.

WE have to record, with much regret, the death of Mr. Frederick Barter, which happened on the 15th ult. on board one of the P. & O. steamers, between Malta and Gibraltar. He was a man who was a credit to his profession, though, for some years past, he has not practised as a gardener in this country. He went out to India (after his return from the Isle of Ascension) in the winter of 1869 to fill a position under the Indian Cotton Commissioners, having been recommended from Kew. Though his time (five years) would have expired this year, failing health compelled him prematurely to return. His father, himself an old gardener now nearly seventy years of age, had gone to Southampton to meet his arrival, when he received the sad news that he had been buried at sea. Another of his sons, Charles, fell a victim to fever some years ago up the River Niger whilst botanist to the Niger Expedition under Captain Baikie. Charles was once in the Regent's Park, and sent home many new plants from the neighbourhood of the Niger.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CAN PINE-GROWING BE MADE PROFITABLE?

"THESE are the things that do not pay, are they not?" said a gentleman to me not long ago when looking into my Pine-pits; and, when he said so, it occurred to me that he expressed a very prevailing opinion among proprietors, founded, it must be admitted, upon facts in a good many cases. The question, too, is all the more pertinent now, because the English Pine-grower is likely to find a very formidable opponent in his brother cultivator in the Azores, from which we are yearly getting an increased quantity of fruit of the best description, and which has already had the effect of reducing the prices in our markets considerably. As yet, however, the supply of these Pines has been confined to the autumn and winter months chiefly, and it is questionable if the St. Michael Pine-grower will ever be able to enter into competition with the English grower during the late spring and summer months. English gardeners will, therefore, still have to be depended upon to keep up the supply during these months; and this, I maintain, they can do profitably. Let us begin with good-sized suckers in September. These should be divested of their bottom leaves as far as the stem is of a brown ripe colour; and, after the heels have been cleaned with a sharp knife, they should be potted in 8 or 9-inch pots, deep enough to bury the stem considerably above the base of the bottom leaves. A good fibry turf, chopped small, to which may be added a good sprinkling of bone-dust, is the best soil that can be used; but the Pine will do exceedingly well in ordinary garden soil, sifted and mixed with about its bulk of decayed hot-bed manure, and one-third or more of clean river or silver-sand. It may be said of the Pine—as is said of many trees and shrubs—it will thrive in any ordinary soil if it has head-room, light, and air. The pots should be crocked about 1½ inches deep, and the suckers must be potted very firmly. I always ram the bottom layers with a wooden rammer, and then fill in around the sucker, making the soil as hard as finger and thumb can make it. A compact firm soil is one of the best aids to a woody and well-matured stock. When potted, they should be plunged in the succession pit near the glass, which should be kept clean. Shading in September will only be required on sunny days, and should be discontinued in a fortnight after potting, if all has gone well. A bottom-heat of 85° must be kept up for three weeks, and a top-heat of 75° by night and 85° or 90° by day. The plants should be dewed over with clean tepid water morning and afternoon, except on very dull days, and little or no air should be given during that time. By the fourth week the plants will be fairly rooted, and, if needful, they may be watered thoroughly. Up to this date the syringing will have been sufficient if the soil was in a properly moist condition at potting time, which it should be. After the plants are rooted, however, and a more liberal supply of air is given, they will want more water at the root, and when they are watered, it should be done thoroughly, each plant should get a good soaking. The Pine requires as much water as any ordinary stove plant, and unless it gets it, it will not thrive. Towards the end of September syringing over head should be discontinued, and the bed only sprinkled, but the evaporating troughs may be kept full always. The bottom-heat should also be reduced to 80°, and by the end of October to 75°, while the night temperature may range from 60° to 65°, and the day from 65° to 75°, according to the weather. These temperatures are adhered to here as nearly as possible all the winter, and, by long and constant experience, I find they are just sufficient to keep the roots and leaves in healthy action without growing much, which is all that should be aimed at; growth in winter, under a too high temperature, is only an elongation of the leaves, and is good for nothing. On the other hand, if the temperature, top or bottom, gets too low, the roots will perish, and the leaves will damp off in the hearts of the plants; and if, through timid watering, the soil in the pots is allowed to get too dry, the

plants will go to rest, and, probably, many of them will show fruit prematurely in spring. Against these accidents, growers always put in more suckers than they want, discarding the surplus stock in spring at potting time. By the beginning of March, soil, the same as recommended for the suckers, should be prepared for potting. It should have the chill taken off it before using, and the potting should be done in some comfortable place. At the same time the requisite number of 12 or 14-inch pots should be got ready and crocked, and, when everything is prepared, the plants should be turned carefully out of their pots, the ball of soil just reduced sufficiently to disentangle the roots, and transferred to the larger size, potting firmly as directed in potting the suckers. The plants should then be transferred to their summer quarters, and plunged, at least 2½ feet apart—if more room can be afforded all the better. The bottom-heat must be raised to 80°, and the top-heat to 70° at night, and from 80° to 85° by day, and shading, dewing, and keeping close for a week or two must also be practised as with newly-potted suckers. The prospect of fruit now depends upon the treatment from this date. Towards the end of March the bottom-heat should be raised to 85°, the minimum top-heat to 75°, and the maximum to 85° or 90°, according to the weather. These temperatures should not be exceeded, but they must be adhered to as closely as possible, especially in the bottom-heat, till the end of August, always ventilating freely on all occasions consistently with keeping up the proper temperatures. Water, also, must be given at the roots as often as needful, and in abundance. In addition to watering the plants, I frequently in hot weather, deluge the bed in which the pots are plunged; it helps to keep the atmosphere sweet and moist; but, with plenty of water at the root, a Pine will thrive luxuriantly without shutting up or syringing at all. Frequent waterings with weak liquid-manure should also be given during the summer. If these simple directions are followed, the plants cannot fail to thrive, and, by August, robust stocky plants will be the result, such as will be sure to bear fine fruit the following summer. By September the bottom-heat should drop to 80°, also the top-heat proportionately, and it should still further decline by October to 75°, and the top-heat to 65° minimum, and from 75° to 80° maximum. If this descent is gradual, the plants will complete their maturation and go to rest entirely by November, when the bottom-heat should not exceed 70°, nor the top 75° maximum, nor 60° minimum; nor will the plants require much water at this time, though they must not be allowed to become parched in the least. If fruit is wanted in May or June the plants must be started again by the end of November, and to this end the bottom-heat must be raised to 75° and the top-heat proportionally, and this figure must not be exceeded till the plants show fruit. It is very often at this stage that the prospect of a crop is ruined. It is not at all an uncommon thing for growers to jump the bottom-heat to 85° or 90° at once, and, unless the fruit is almost already visible, which it should not be under proper management, the chances are a hundred to one that the plants will throw up a tuft of leaves instead of fruit, and they will not fruit afterwards. Anyone can satisfy himself on this point by experiment. I would undertake to make the best ripened plants miss fruiting by this treatment. It is exactly the same with forced Strawberries, Peaches, and other things, only a more rational practice is usually adopted with these. The Strawberry, particularly, will not bear pushing at the first; if it is, it will simply throw up a crowd of leaves, and the flower scape will rarely even get out of the socket, and if it does manage that length, the flowers will be weak and useless. Once the Pines have shown fruit, both top and bottom temperatures must be raised another 5°, and, after they have done flowering, they may be treated to the ordinary summer temperatures of the year before, which should be kept up till the fruit is ripe and the suckers are fit to be detached for another stock. If well-swelled glistening fruit, with the juice almost oozing out of the pips, is desired, watering must never be discontinued, even when the fruit is quite ripe, though damping overhead may be given up, and more air given. In other respects, the treatment during the fruiting period should be the same as during the growing season.

J. S. W.

NOTES OF THE WEEK.

— THE fine specimen of *Agave univittata*, in the succulent-house at Kew, is now bearing a flower-spike some 9 or 10 feet in height. This Aloe, which is one of the most distinct of the spicate group, has leaves prettily striped in the centre with yellowish green.

— WE learn, from the *Gartenflora*, that the extensive herbarium of the eminent Greek botanist, Orphanides, has been purchased by Herr Rhodocanaki, of Odessa, and has been presented by him to the University of Athens.

— MR. WILLS writes to us respecting the fine conservatory figured in last week's GARDEN, and requests us to state that the plants in it were supplied and arranged by him. Better, or more suitable subjects, or a more effective arrangement we have not seen.

— A FAIR number of entries, it is said, have been made for the prizes offered by the Royal Agricultural Society for disease-proof Potatoes. The competitors evidently have confidence in the virtues of their varieties, for, in the event of failure, they are liable, for cost of cultivation, to the amount of £20.

— ARTIFICIAL nests have been suspended in many of the trees in the Bois de Vincennes, near Paris, with a view of attracting birds that may prove useful in destroying insects. The attempt was first made last year, with the result of filling about sixty per cent. of the nests.

— IN his address at Trenton, Mr. Quin gives the Strawberry crop of New Jersey at 2,000,000 quarts in favourable seasons, worth, at 16 cents per quart, £60,000; Blackberries, Raspberries, and Grapes, about as much more. He estimates the Cranberry crop at 125,000 bushels of sound fruit (worth about £60,000), and more than half the entire crop of the country, and bringing into use thousands of acres of swamp lands which could not otherwise be employed.

— WE (*Pharmaceutical Journal*) have been favoured with a communication from Mr. Daniel Hanbury, in which he states that having recently had occasion to search some old newspapers in the British Museum, he observed the following advertisement in the *Mercurius Politicus*, No. 435, September 23rd to 30th, 1651, which, though probably well-known to antiquaries, may be interesting to some of our readers:—"That Excellent, and by all Physitians approved, China Drink, called by the Chineans, Tcha, by other Nations Tay alias Tee, is sold at the Sultaness-head, a Cophee-house in Sweetings Rents by the Royal Exchange, London."

— THE common wood Nettle of America has been transplanted to Europe by M. Rossel for the purpose of being applied to textile purposes. It is known botanically as the *Laportea pustulata*, and is perennial. As it is, therefore, unnecessary to sow the seed each year, the plant has, in this respect, an advantage over hemp or flax, while it is said to necessitate less labour and expense in preparing the fibre. In a wild state, the Nettle attains a height of 2 or 3 feet; but we learn that those that have been cultivated in Berlin have already exceeded this limit, and it appears possible that, by care and proper soil, even a still greater altitude may be gained.

— AT a recent meeting of the French Academy of Sciences, M. E. Faivre read a paper detailing a series of experiments in support of the theory that the fluid which supplies the tissue of plants with food ascends beneath the bark. He found that, when strips are cut away from the bark of trees, the buds always continue to develop when a communication is still left between them and the lower part of the tree; while, if this communication is completely destroyed, the buds wither away. If a complete ring was removed beneath the bud, it withered away the more slowly the greater the distance of the strip from the bud. The starch disappeared in these cases from the portions of the wood above the cut piece, and between it and the bud, while beneath the cut it remained unchanged. If cylinders of bark are left, bearing buds, they may be made to develop even into branches.

— THE reports of the ravages made among the Potato crops in the United States last year by the Colorado beetle have naturally caused considerable alarm to growers in this country, as it is feared that this insect pest may be brought over in the large quantities of seed Potatoes which are imported from the other side of the Atlantic. With a view to preventing its introduction, Mr. J. Algernon Clarke, secretary of the Central Chamber of Agriculture, addressed a letter, on the 10th of February, to Mr. Gladstone, calling his attention to the imminent risk to which the United Kingdom, especially Ireland, is exposed, and suggesting that the importation of Potatoes from the United States and British America should at once be prohibited. In reply, a letter was received last week from the office of the Privy Council for Trade, to the effect that, according to the American official reports, it does not appear that the eggs or larvæ of the Colorado beetle have been, or are, deposited or conveyed in the tuber of the Potato; and, therefore, there is considered to be no reason to

prevent the importation of seed Potatoes from America into the United Kingdom until the case is proved to be otherwise. We think this a wise decision.

— OUR correspondent, Mr. George Gordon, A.L.S., author of the "Pinetum," has been appointed one of the jury for awarding the medals at the Great International, Botanical, and Horticultural Congress, to be held at Florence, in May next.

— A HORTICULTURAL curiosity is now on view in the Crystal Palace, in the shape of a Hyacinth with no fewer than eleven flower-spikes, all excellent ones, issuing from the same bulb, the total number of bells being 170. The variety is Norma, a flesh-coloured kind.

— It is worth noting that (according to a report made to the Lyons Society of Industrial Sciences) the Broom (*Sarothamnus scoparius*) which grows so abundantly in many parts of this country, and which has been long known to yield a yellow dye, and a fibre which has been used as thread, may, by a little care, be made to produce a fibre quite equal to hemp, in strength and fineness.

— MESSRS. HOOPER & Co., of Covent Garden, have imported roots of a *Begonia* (*B. octopetala*) new to cultivators in this country. The foliage of the plant, as shown in a beautiful drawing before us, is of a fresh green tint, and, in shape, not unlike that of a very large fancy *Pelargonium*; while the flowers, each as large as a crown-piece, are of pearly-whiteness in front, and deep rosy-carmine behind. It is a native of Peru, and is said to grow well in a cool-house.

— THE second number of the *Illustration Horticole*, just published, contains beautifully-coloured plates of *Anthurium floribundum*, a deep glossy-leaved Arad bearing milk-white spathes; *Lasiandra lepidota*, a very showy greenhouse *Melastomad*, bearing deep rosy-crimson flowers, each as large as a crown-piece, while, in general habit and mode of flowering, the plant has some resemblance to the well-known *Pleroma elegans* (it inhabits the cold regions of the Cordillera of the Andes); *Pritchardia pacifica*, a deep green glossy-leaved Fan-Palm, a native of the Fiji Islands and Polynesia, where it was discovered by the late Dr. Berthold Seeman.

— THE first number of "Orchids, and how to grow them in India and other tropical climates," by J. Jennings, F.L.S., has just been published by Messrs. Lovell, Reeve, & Co. It is a royal quarto, printed on fine paper, and embellished by four coloured plates of the following choice Orchids, viz., *Cattleya exoniensis* (rosy variety); *Dendrobium Wardianum*, a richly-tinted form, first figured in the *Botanical Magazine* as *D. Falconeri obtusum*; *Angræcum sesquipedale*, a good figure of this pearly-white Orchid; and the new *Cypripedium Sedeni*. The author treats his subject in a straightforward manner, likely to be appreciated by amateur Orchid-growers, while some of his Indian experience will be valuable to our cultivators here at home.

— THE Botanical Society of Edinburgh offers a prize of ten guineas for the best and improved essay on the reproduction of *Lycopodiaceæ*, to be competed for by students who have attended the botanical class at the Royal Botanic Garden, Edinburgh, during, at least, one of the three years preceding the award, and have gained honours in the class examinations. The author is expected to give results of practical observations and experiments made by himself on the subject, illustrated by microscopical specimens. The essay and specimens to be given in on or before 1st May, 1876, with a sealed note containing the author's name, and a motto outside. Facilities will be given for carrying on observations and experiments at the Royal Botanic Garden, Edinburgh. A prize of ten guineas is also offered, through the council of the Botanical Society, by Charles Jenner, Esq., for the best and approved essay on the Structure and Re-production of the Frondose and Foliaceous *Jungermanniaceæ*. This prize is subject to all the conditions specified above.

— It may be of interest to know that, in connection with the reception of the Duke and Duchess of Edinburgh, at Windsor, on Saturday last, Messrs. Veitch & Sons, of Chelsea, had the honour of offering to Her Majesty, the Princess of Wales, and the Duchess of Edinburgh, splendid bouquets composed exclusively of the rarest Orchids, Roses, and Lilies of the Valley. The Queen and the Princess of Wales were pleased to receive their's personally from Mr. Harry J. Veitch, Her Majesty retaining also that for the Duchess of Edinburgh for presentation on her arrival at the Castle. The floral decorations for the banquet given on Monday, in honour of the newly-married couple, were very extensive. Five large groups of Palms, Musas, and other fine-foliaged plants, interspersed with choice flowers, were very effectively arranged on the grand staircase by Mr. Jones, Her Majesty's gardener at Frogmore; whilst, in the reception rooms, the fire-places were, as usual, most tastefully filled by Mr. Turner, of the Royal Nurseries, Slough, who also supplied all the plants and flowers required for the banquet table. The whole of the table decorations at Buckingham Palace, on Thursday last, were supplied by Mr. John Wills.

THE INDOOR GARDEN.

ATACCIA CRISTATA.

THIS very curious plant—one of the most extraordinary we are acquainted with—is a native of the islands of the Malayan Archipelago. Though by no means new, it is far less commonly seen than it ought to be, considering the ease with which it is propagated, and the anomalous features it presents in regard alike to aspect and to structure. The love and admiration given to flowers, for the sake of their bright colours and their sweet scent, are well deserved, and there can never be too much of either. We must confess, at the same time, that we like to see intellectual interest in what may be termed the vagaries of nature. Nature's ways are very imperfectly apprehended so long as we rest content with Roses and Lilies, Fuchsias and Primulas. The plant before us was originally introduced into the gardens of Kew, under the generic name of Tacca. The other members of this curious Indian genus have multifid leaves, and the roots are tuberous. *A. cristata*, having undivided leaves and a rhizome, was separated by Presl, who gave it the name of Ataccia; and in this he was followed by Endlicher and Kunth, though both express their doubts as to the necessity of the new genus. What differences may lie in the essential characters appear to be but trifling; and a distinction founded alone, or chiefly, upon habit and foliage, is usually considered unimportant. But, leaving the doctors to decide, we take the name as we find it, and commend the plant to every one who has a liking for the exceptional. The underground portion consists of a short and conical root-stock, marked with the scars of former leaves, and here and there throwing up some small gemmæ or tubers, by the removal of which it is readily multiplied. The actual roots consist of a few coarse fibres. From the crown of the root-stock rise three or four handsome and dark green leaves, the petioles several inches in length, the large and elliptic-oblong blade acuminate, entire, and elegantly veined, the veins flowing in parallel curves. In the midst rises a stout scape,

like that of a Hyacinth, twelve or eighteen inches in height, quite erect, and bearing on the summit a unilateral and half-pendulous umbel of twelve to twenty brownish-purple flowers, each as large as the top of one's little finger. In figure they are not unlike the flowers of the Asarabacca, having a turbinate and six-angled ovary, to which the lower portion of the perianth is adherent, while the six triangular lobes, all of the same size, are reflexed upon it in such a way as to give a circular mouth, of precisely the same truncate character as that of the Cyclamen. But here, instead of pure white, or lovely lilac-rose colour, we have sombre and lurid purple, and, moreover, the matchless twist of the Cyclamen is wanting. So completely are the perianth lobes laid back against the ovary that, at first sight, the flower seems only a circular muzzle, with half-a-dozen stamens for quaint front teeth. The petioles supporting these odd flowers are about an inch and a half in length. Intermingled with the floriferous ones, or, perhaps, rather behind, and somewhat laterally, are many more that are abortive, attenuated to a length of at least 12 inches, and hanging down like thin straight hair, a lock upon either side; while, at the back of all, stand up two enormous vertical bracts, and two smaller ones, the former resembling the sheaths of the common English Arum, but flattened out, and of a cadaverous greenish-purple hue. The

whole thing is so weird and gipsy-like that one almost starts at the supernatural mockery. Had the witches in "Macbeth" wanted a flower a-piece on a certain celebrated occasion, and, had the plant grown at home instead of ten thousand miles away, this Ataccia, of all the productions of nature, would have suited them best. Ovid would have been glad of it for an additional legend in the Metamorphoses. It is very easily propagated; all that is necessary is to detach one of the gemmæ from the rhizome, and place it in a small pot of light loam and peat, giving plenty of water, and preserving it, at all events while the plant is young, in a close moist atmosphere. We have seen the Ataccia in many good collections of curiosities, especially near Manchester, and, no doubt, it is to be had from the leading nurserymen.

LEO GRINDON.

GARDEN AQUARIA.

THE culture of aquatic plants seems, for the most part, limited to our large public and private gardens, such as Kew, Chatsworth, or Syon House; but proper appliances for the culture of the smaller kinds cost but little, and, by adding them to our plant-houses, we may greatly increase the beauty and interest of our collections. A large and expensive structure for growing the Victoria Lily cannot be erected in every garden, but, every one who possesses a plant-stove, greenhouse, or conservatory, may, with but little trouble or cost, devote some portion of it to the cultivation of the more beautiful water-plants. Aquatics and succulents may be grown by the merest novice in plant-culture, since they require so little attention after they are once planted. Watering plants is a source of trouble to most gardeners; but, in succulents, this is reduced to a minimum, while, in the case of aquatics, they are, of course, always well supplied, though a change is occasionally desirable. The introduction of a slate tank into the plant-stove occasions but little extra trouble and expense, while it may be made one of the most interesting features in the house; or one side of the side-benches might

Ataccia cristata.

be covered with several of these shallow tanks placed side by side. Their size will vary according to the width of the staging, but from 3 to 4 feet square, and a foot or 15 inches deep, will, in most cases, be amply sufficient. These portable tanks are, in many cases, preferable to permanent erections, as, during the winter months, they can be removed and stored away in any dry shed until required for the next season, or the water they contain may be emptied out and plants in pots can then be set inside in the usual way. In tanks like those above described, a great variety of the smaller aquatics can be grown that will not be less interesting to the ordinary visitor than the more common terrestrial plants grown in pots. We want variety in our gardens, and the culture of aquatics is one way to set about obtaining it. Among the commoner aquatic plants there are some which should be in every garden, as the Aponogetons, their forked sprays of silvery bracts being most valuable for cutting. *Vallisneria spiralis* is always interesting as a microscopic object, and some of the smaller tropical Water Lilies grown in tanks like those above described, unfold their pure white, bright rose, or coerulean blue flowers, as freely as those of our native ponds and streams. A little good sandy loam is the best compost in which to plant the stronger-growing kinds, while some of the smaller Pistias and Pontederias will float on the surface. These tanks are valuable for assisting the

growth of other plants as well as aquatics; for example, Palms grow far more vigorously during the hot summer months, if the bases of their pots are sunk about 2 inches into the water. This is best effected by setting the pot, in which the plant is growing, on another pot reversed beneath the water in the tank. *Richardias* (Callas) grow far more robustly and flower better if the pots are plunged overhead in the water, and if they are sunk deep enough, say, from 2 to 3 feet, the plant will withstand our climate all the year round, and form a noble ornament on the margins of ponds, lakes, streams, or other ornamental waters. We will now give a short descriptive list of aquatics best adapted for growing in shallow stove-tanks indoors.

Aponogeton distachyon.—An old plant in our gardens, having been introduced from the Cape in 1788, but never very generally cultivated. It is nearly allied to the Lattice-leaf or Lace plant of Madagascar, and has similar venation, but in the case of the *Aponogeton* the intervening spaces between the veins are filled with cellular tissue. It is one of the most accommodating of all plants, as it may either be set in a drawing-room window, planted in a little earth at the bottom of an inverted bell-glass, or it will grow vigorously in a shallow tank in the open air, where it seldom fails to flower freely throughout the spring and summer months.

A. monostachyon bears pretty pink blossoms on its undivided spikes. It is smaller in habit than the last-named, and, being a native of the East Indies, requires the warm humid temperature of the stove aquarium.

A. angustifolium, a narrow-leaved form, was introduced from the Cape in 1788, but is now lost to cultivation.

The Water Fern (*Ceratopteris thalictroides*).—A rare Fern, and one of the few that grow well plunged in water. It grows beautifully in a shallow tank in one of the stoves at Chatsworth, and has recently been added to the Kew collection. It is of a fresh green colour, and a most vigorous grower in a hot moist stove.

Umbrella Sedge of Madagascar (*Cyperus alternifolius*).—We have here a forcible example of the adaptability of plants. Grown in a pot in ordinary compost, this makes pretty little plants 1 to 2 feet high, and well adapted for ordinary decorative purposes; but, if planted in a pot of rich soil, and partly plunged in the tank, it often produces large growths 5 or 6 feet in height. In the Palm-house at Kew there is a curious glaucous variety under this name, with stems between 4 and 5 feet high, the leaves at their apex being only 5 or 6 inches in length. There is also a pretty variegated form, very valuable for decorative purposes, although it is apt to revert to its normal green state. If the plant is grown in very poor soil, with at least one-half of sand, it comes beautifully coloured, each leaf being striped with pure white. This plant is always useful, especially for table decorations, and for grouping along with choice flowers in the drawing-room vases. Its foliage radiates in a gracefully drooping manner from the apex of the slender stems, and is distinct from any other decorative plant.

Limncharis Humboldtii.—This plant bears beautiful, clear, soft yellow flowers among its floating foliage. The general port of the plant is similar to that of *Aponogeton distachyon*, but its leaves are heart-shaped, and the plant is sufficiently hardy to stand out-of-doors in sheltered tanks during the hottest portion of the year only. Grown in the shallow stove-tanks above alluded to, it grows and flowers vigorously, forming a really beautiful object.

Nymphaea cœrulea.—This is a pretty little plant, that grows and blooms well in any plant-stove treated as an aquatic. It has bright green foliage and light blue flowers, both of which float gracefully on the surface of the water. *N. pygmæa* is a charming companion to it, and might readily be grown in an inverted bell-glass a foot wide, as recommended for the *Aponogeton*. It has fresh heart-shaped leaves, and pearly flowers of the most pearly whiteness.

Nelumbium speciosum.—This is the well-known "Sacred Bean" of Egypt, and is best treated as a sub-aquatic, or it can be grown in a tub half filled with good sandy loam covered with about 12 inches of water, so as to keep the roots in a consistent state of moisture. This makes a fine object, having large peltate leaves borne on long stems, and great rosy-tinted *Nymphaea*-like flowers. Its seeds are borne in a peculiar top-shaped head perforated with holes, something like the rose of a watering-pot. It is easily propagated from seeds sown directly after Christmas.

Common Water Lettuce (*Pistia Stratiotes*).—This plant is of a light and fresh green colour, and forms a most interesting object in the stove aquarium, as it floats on the surface of the water in a manner analagous to our common Duckweed (*Lemna*). Its leaves are arranged in a rosulate manner, and are 2 to 4 inches in length, by about half the width, while their general appearance certainly

does give one an idea of Lettuce, whence its popular name. This plant readily propagates itself by offsets.

Pontederia crassipes.—This is a most curious plant, having inflated leaf-stalks to its kidney-shaped leaves, and which give it the general appearance of a *Sarracenia*. It should be grown in every stove tank as a most interesting and curious object.

Vallisneria spiralis.—This is a Grass-like plant, which roots freely into the mud at the bottom of the tank, and sends up its female flowers on long spiral hair-like stalks, often 15 inches to upwards of 2 feet in length. It is a popular plant for indoor or parlour aquariums, of which we shall treat more fully in a future notice.

F. W. BURBIDGE.

CYPRIPEDIUM IRAPEANUM.

THIS rare Lady's-Slipper is a native of the Savannahs of Upper Mexico, where it is found at an elevation of from 3,000 to 4,000 feet. It grows about 2 feet high, the stem bearing 3 or 4 oblong, acute, pilose leaves, with undulating margins. The flowers are large (being 4 to 5 inches across), with broad petals of a clear sulphur-yellow, and a large golden-yellow lip, marked inside with crimson spots, reminding one of a yellow-flowered herbaceous *Calceolaria*. They are borne, one or two, on the summit of the stem, and, in form, resemble those of *C. spectabile*, except that the petals are broader. This plant has been frequently introduced into European gardens, but, from ignorance of its requirements, or other causes, has hitherto been found difficult to keep alive for any length of time. The following communication, on the subject of its culture, from the Comte du Buysson, appears in a recent number of the *Illustration Horticole*, and may be interesting to some of our readers:—

I plant this *Cypripedium* in a deep pot, 7 or 8 inches in diameter, thoroughly drained by a thick layer of crocks and coarse gravel, and then filled with a compost formed of equal parts of turf-soil or alluvial meadow-soil, heath-soil in lumps, and the *detritus* of wood, such as the hillocks of the large wood-ants are composed of (an excellent and handy material, which I use for all my Orchids). In potting, I spread the roots of the plant well out, and cover them deeply, so as to have about 2 inches of soil over the point where the stem issues from the root-stock. This operation should be performed when the plant is about to commence growth, in February or March. The pot should be placed on the front of a shelf or bench in a temperate house, facing the south, in the full sunshine. Water, at first, very lightly, until the stems appear overground, then, by degrees, more freely, according to the state of growth, and, as may be needed, never allowing the soil to become dry, until after the plant has done flowering. When the stems have made their appearance, give air night and day, except in bad weather; when the flowers are fully expanded, remove the pot either into a room, or to a shady part of the green-house. This will prolong the time of flowering, which commences in June and continues for nearly two months. As soon as the flowers shall have all faded, gradually diminish the supply of water, so that the leaves and stem may dry off, when the soil should be left dry from November to March. The plant should then be re-potted and treated in the same manner as before. The long winter rest will secure the preservation of the plant, by permitting the root-stock to become perfectly matured. The treatment is, in fact, the same as that required for plants of the *Gesneraceæ*; the temperature being kept at from 43° to 55° during the season of rest, and at from 66° to 100° during the period of growth in summer.

[To the foregoing, M. Linden appends the observation that he has frequently introduced this plant into his hot-houses, and treated it in almost precisely the same manner as that recommended by the Comte du Buysson, but without success. We understand that this difficult Orchid has been grown, for the last year or two, in the most satisfactory manner by the Messrs. Backhouse & Son, in the York Nurseries.—Ed.]

RENANTHERA COCCINEA AT DALVEY.

THIS, being one of the shyest blooming of Orchids, is usually submitted to a variety of temperatures, varying from that of the intermediate house to that of the warmest department in the establishment, but, at no place have I seen it receive less special care than at Dalvey, and there it not only grows freely and healthily, but blooms abundantly. The Orchid-house in which it is grown is a long

spanned-roofed house, running north-east and south-west, and is heated by 4-in. hot-water pipes, of which there are more at the end nearest the boiler than at the other end, where the *Renanthera* is grown. The winter temperature of this house at the warmest end is 55°, and at the coolest end it varies from 43° to 45°. In the centre of the house is a long bench or table, of Caithness flagstones, on which are set the largest specimens of Orchids, some of which are in pots and some in tubs; whilst, from the roof hang numerous blocks and baskets. On the surface of the bench, between the specimen Orchids, is a thin layer of earth, consisting of peat, charcoal, Sphagnum, crocks, &c., part of it having been placed there purposely, and part of it washed from the Orchid-pots in the process of watering and syringing. In this earth some Orchids, a great variety of Ferns and Selaginellas, together with *Eranthemums*, *Gymnostachyums*, *Achimenes picta*, *Tradescantias*, and many other pretty little old-fashioned plants grow luxuriantly, quite uncared for. Surrounded by this semi-natural vegetation, in a pot on this bench at the coolest end of the house, the *Renanthera* in question is growing. It was originally planted in sphagnum, turfy peat, and crocks, and trained upwards to the roof on strong branched and peeled Oak stakes. It has now, however, out-grown the limits at first assigned to it, and its roots ramble, here and there, over other pots, and amongst the soil on the slate. Mr. Berry, the gardener, attributes his success in flowering this plant to its being allowed to grow in this negligent manner, and to its top being near the glass, where it gets plenty of light, and but little shade in summer.

W. F.

MAMMILLARIA SULCOLANATA.

THIS stout-growing species from high latitudes in Mexico, belongs to the same section as *M. elephantidens*. The *Mammæ*

Mammillaria sulcolanata.

are globose, and terminated by a set of from eight to ten strong reflexed spines, $\frac{1}{2}$ inch in length. It grows from 5 to 6 inches high, and is not so prolific as *M. elephantidens*. At the base of the *Mammæ* is a dense forest of white wool, which disappears as the plant gets old. Its flowers are yellow and $1\frac{1}{2}$ inch in width; indeed the whole of the section has large reflexed yellow flowers, very distinct from those of ordinary *Mammillariæ*, which have short bell-shaped blossoms, which scarcely protrude beyond the spines, and are produced in whorles, while in this section they spring from the apex, as in *Echinocacti*. They do not require much heat, and if not kept well away from fire-heated surfaces during winter they get over-run with red spider, and often die; otherwise they are easily grown, and flower from July to November in the open air in the same way as Alpines do; in fact, if treated like Alpines, except that they must be dry during winter, they do very well. Offsets treated liberally will flower the second season.

J. CROUCHER.

***Sobralia macrantha*.**—This is a splendid Orchid, in the form of a large specimen, but it is a shy flowerer when small. We saw a noble plant of it at Dalvey the other day, which, every season, produces scores of flower-spikes. It occupies a tub 3 feet in diameter, and is growing in a compost consisting of rough fibrous peat, Sphagnum, and crocks; the tub is placed on a central stone table in a span-roofed Orchid-house, and the shoots or reed-like stems, of which there are quite a forest, varying from $3\frac{1}{2}$ to 5 feet in height, run up to within a foot of the glass. The night temperature of the house is about 45° in winter, and 65° in summer. As regards watering, it gets abundance, both at the root and overhead in summer; but, in winter, owing to the low temperature at which the house is kept, it only gets enough to keep the roots from suffering, and not a drop overhead. The roots of this *Sobralia* being fleshy and very brittle, the greatest care is exercised in re-potting it, an operation, however, only needed at intervals of several years, as by keeping it pot-bound, it is more floriferous than if it were permitted to have more root-room.—W. F.

Rare Orchids now in Bloom.—*Vanda Cathcartii*, a tall-growing species resembling a robust *Renanthera*, bearing pendulous spikes of fleshy-streaked brown flowers, with a lemon-yellow lip. *Angræcum citratum*, a pretty little species, bearing slender spikes of creamy-white flowers 16 inches long, the flowers being very regularly arranged, and each furnished with a curiously bent spur; *Lælia Jongheana*—In habit this is identical with *Cattleya marginata*, and has rosy-lilac flowers with a fringed lip; *Masdevallia Lindeni*, a richly-coloured species, bearing flowers of the finest silvery-purple or majenta. No coloured drawings at present published have done justice to these richly-coloured Alpine Orchids. They are all readily grown in a cool temperature, and, as they are vigorous in habit, and most profuse bloomers, they deserve general cultivation. *Dendrobium thysiflorum*—This is one of the finest of the whole genus, but, unfortunately, very short-lived. Its flowers are produced on drooping spikes, the sepals and petals being of pearly-whiteness, the latter elegantly fringed; while the crumpled lip is densely set with short hairs, and contrasts well with the other segments, being of a deep orange-yellow. This is the best *Dendrobe* of the class, of which *D. densiflorum* may be considered the type.—B.

***Cymbidium Mastersii*.**—Many Orchids bloom in winter that are not really winter-flowering, but *Cymbidium Mastersii* may be reckoned amongst the best of true winter-flowering plants. It is a native of the East Indies, and requires the temperature of a *Cattleya*-house to grow it well. It may be successfully cultivated in the *Odontoglossum*-house, where it would flower some weeks later than more warmly-nursed plants. The leaves are of a deep green colour, gracefully arched, an inch wide, 18 or 20 inches long, and the flowers are of a yellowish-white colour, with a blotch of yellow on the lip. They are large, and borne thickly on spikes of from 15 to 18 inches in length, as many as sixteen blooms being frequently produced on a spike. If transferred from the house where they are growing when they are opening their flowers to a shady corner in a cooler one, they retain their beauty for a considerable period. They commonly come into flower in November, and continue blooming until January, when *Cymbidium eburneum* may be coming in. Both of these are extremely like one another in foliage, but there is a marked distinction in the construction of the flowers, those of the latter being more beautiful than those of the former. It is also a free-flowering, easily cultivated, showy, winter-blooming plant.—WM. FALCONER.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

***Echeveria metallica*.**—Not only is this a most useful plant for summer decoration in the flower and rock-garden, but it is also a very ornamental plant, especially when it has obtained a large size, for blooming under glass in winter. We have several large plants of it that were lifted and potted last October, when in bloom, that have been in flower ever since, and the long-branching spikes of wax-like flowers have a very striking appearance.—E. HOBDAY, *Ramsey Abbey*.

***Asphodelus acaulis*.**—A plant of this rare plant was exhibited the other day at South Kensington, by Mr. Munby. It has slender Rush-like leaves of a fresh green colour, that curve gracefully in a rosulate manner, the flowers being borne in the centre on a very short stem. The individual flowers are of a rosy-salmon colour, with a streak of green up the back of each segment. The plant is a native of Barbary, and is rare in collections of half-hardy herbaceous plants. Although not showy, its distinct habit and colour recommend it to the consideration of amateurs.—B.

***Crassula quadrifida*.**—This is a most profuse-flowering plant, the inflorescence of which somewhat resembles that of *C. lactea*, but is stronger, and the buds and tips of the petals are pink instead of white; indeed, the flower-spike forcibly reminds one of that borne by the London Pride (*Saxifraga umbrosa*). Its leaves are very distinct, being of a bright green and distinctly pitted, while their apices are retuse. Like other species of this genus, it may be readily propagated, and grows vigorously in any ordinary apartment. The compost best suited for it and its allies, is one consisting of crocks, sandy loam, and lime rubbish, on a well-drained bottom. It is a most valuable addition to succulents adapted for window-culture. It blooms in March, or about a month later than the better known milk-white *Crassula* (*C. lactea*).—B.

THE PROPAGATOR.

PROPAGATING AUCUBAS.

THESE are propagated by means of seeds, cuttings, layers, and grafts.

Seeds.

The finest of the berries should be gathered when thoroughly ripe, freed from the pulp by washing in water, and sown in seed-pans half-filled with drainage, and made up with sandy loam. After sowing, store the pans in cold frames or pits, where they had better be kept until the plants have appeared, and have grown sufficiently to require shifting. Then, instead of potting them singly, prick them off into other boxes or into a frame, and keep them well exposed whenever the weather is mild. By the time they are two years old they will be fit for transplanting into the open ground, but this operation is frequently deferred until the third year. When thus transferred, a piece of sheltered ground should be provided for them, and, although partially shaded by trees, that is a matter of no importance, as the *Aucuba* does well in company with such plants as *Hypericums*, *Berberis*, *Ivy*, and *Periwinkles*, that grow under shady trees, and thrive where even Grass can scarcely exist.

Cuttings.

This mode of increase is that which is usually adopted, and, as the *Aucuba* strikes freely, the cuttings are subjected to many different sorts of treatment. Half-ripened wood makes the best cuttings, and August and September are the best months for propagating in this way. Cut off as many branches from the old plants as can be spared, and divide them into pieces having two or three eyes each, and also one or more leaves. For these prepare a cold frame or border at the base of a wall, wooden fence, or hedge, mix a good deal of sand and some leaf-mould with the soil, and, in this, insert the cuttings pretty thickly and firmly. If in frames, cover with sashes, and shade from sunshine, but, if in borders, hand-lights should be employed. Here the plants may remain till next April or May, when most of them will be rooted, and, consequently, may be potted off singly into 60-sized pots, and kept in frames or plunged in ashes in a north border, or they may be transplanted further apart in other frames, or into lines in sheltered and shady positions out of doors. Some prefer nipping out the soft points of the cuttings, so as to induce them to throw up two or three shoots instead of one. Where the object is to strike them quickly instead of slowly, they should be inserted thickly in 48-sized pots, filled with sandy peat, surfaced with silver-sand, and kept indoors in a gentle heat and well shaded. As fine a "strike" as I remember having seen of them was in the Ashburnham Park Nurseries, where the central bed of one of the propagating-houses was quite carpeted with the common sort. In this bed there was a good depth of Cocoa-nut fibre for plunging pot-plants in; the surface was, therefore, levelled, some sand was mixed with it; and between the pots the cuttings were then inserted; here they rooted early and satisfactorily, and were soon fit for potting and for being transferred to a frame. Sometimes strong shoots of *Aucubas* make awkward cuttings, owing to their robust character and the great distance between the eyes on them, but for this there is a remedy and a good one. Use the best cutting-making parts for that purpose, and cut up the other portions into little pieces, each possessing a single eye and a leaf, and insert them, as recommended for cuttings in pots, in gentle heat, putting several in a pot. A little wooden peg should be applied as a support to each eye-cutting, the leaf being neatly affixed thereto, in a somewhat upright direction, by a piece of matting. Thousands of *Aucubas* are struck in this manner under glass cases in the intermediate propagating-houses at Coombe Wood Nurseries, where they root successfully, although put in as late as the end of October or beginning of November. In the same nurseries, too, I observed current year's shoots from 12 to 14 inches in length, propagated as single cuttings, each being inserted in a 48-sized pot, filled with sandy loam, and inserted in the cases in the propagating pits. These, when rooted, would not make nice permanent plants, but they were used as stocks for grafting on in the following spring.

Layers.

This is a convenient mode of propagation, especially where old plants are grown in broken soil, *i.e.* not on turfed lawns, and it is also useful for furnishing us, at once, with large and well-formed plants. The operation is best performed in August and September; it merely consists, as in the case of most other plants, in bending down the branches near the ground, so that they can be fixed in position by means of pegs pushed into the soil near the middle of the branches. A little slip or tongue should be cut at the bend where, also, the branches should receive a slight twist, so as to somewhat check the flow of sap and cause the ends to assume an easy upright posture. Some prepared compost, consisting of sand, peat, and some nice loam or leaf-soil, ought to be placed with the hand round the incision and bend; then level down the other mould, and press all firmly. In this way all the branches that can be brought down should be layered. Thus the plants should remain for two years, without even pruning out the young shoots that the old stock will inevitably produce; for, from these the batch of layers which are to succeed those at present layered should be selected. At the end of two years from the time of layering, lift the young layered plants, knife-dress them a little, if necessary, root and stem, and transplant them in nursery lines for a season or two till required. No sooner are these removed from the parent stocks, than the young shoots, made since they were brought down, should be layered; and so on, year after year, whenever increased stock is wanted.

Grafting.

This is the method pursued when standards are required; it is, however, more applicable in the case of plants for pot-culture than it is for those for outdoor use. Good clean stems of the common sort make the best stocks, and these are mostly selected from the strongest of the seedlings. *A. vera* is the favourite berry-bearing plant, and, consequently, more of that kind are worked than of any other sort. The operation is done in spring, by means of side-grafting in close gently-heated and well-shaded pits, and as the scions become united, the ligatures, with which they are fastened, are undone, and the heads of the stocks are gradually reduced. Grafting the *Aucuba* is a matter of no great difficulty; therefore, wax of any sort is but seldom used, although a little of it is beneficial as far as excluding wet from the incisions is concerned.

W. F.

Curious Experience of a Hybridiser.—The notion current among hybridists that the male parent exerts its influence chiefly over the fruit, while the female gives character to the plant or tree, is, according to my experience, erroneous. In many of my experiments in crossing Grapes, Raspberries, Strawberries, and Cereals, I have found the pollen to exert an almost entire pre-potent influence, so that scarcely a vestige of the character of the female parent was to be found in some of the cross-bred offsprings. Take, for instance, the Black-cap Raspberry crossed with White Four-seasons. Some of the seedlings bore white fruit, exactly like the male parent, and threw up abundance of suckers, but could not be induced to root from the tips of the canes like the female parent. Again, I have sown white sweet wrinkled Indian Corn, and early in the season removed its own pollen, and then, at the proper time, furnished pollen of some common yellow Indian Corn, then again, some pollen of purple Indian Corn; and when the Corn is ripe, I have found, instead of white sweet Corn, yellow Corn and purple Corn in the same ear, and, in some instances, both yellow and purple in the same kernel, distinctly marked; and yet the female parent, the kernel of seed that produced the stalk, was white sweet wrinkled Corn, showing, in my opinion, three distinct results in the Corn experiment, *viz.*, the power of the pollen to change the colour and shape of the Corn; its immediate effect upon the embryo grain to which it is applied; and also a proof of superfœtation, or, in other words, of one seed being the joint issue of two male parents.—Mr. ARNOLD, in *Albany Cultivator*.

The Lattice, or Lace-leaved Plant (*Ouvirandra fenestralis*).—This reproduces itself freely from seeds, which healthy and vigorous plants ripen perfectly in this country. When ripe, the seeds drop all around the parent-plant and grow. These seedlings, when strong enough to handle, may be planted at once in a pan of loamy soil, and immediately plunged in the water a few inches below the surface. Should the seedlings have fixed themselves to the pebbles, these may be removed with them.—W. F.

THE FLOWER GARDEN.

SCARLET-FRUITED CUCURBIT.

(ABOBRA VIRIDIFLORA.)

THIS plant is nearly allied to the common Cucumber of our gardens, and, although not yet generally cultivated, it is a very graceful trailing or climbing plant, suitable either for the cool conservatory, or for out-door culture during the hottest part of the year. It is well adapted for inside window boxes, and, like most other members of the Gourd family, it does fairly in any moist warm border, or it can be grown in hanging baskets. The foliage is of a deep rich green tint, while in form the leaves remind one of the old green-leaved Stag's-horn Geranium grown in old cottage windows many years ago. The plant is specially interesting on account of its scarlet or bright crimson fruits, which are borne in the axils of the much-divided leaves, and are very ornamental, as they contrast well with the foliage. The flowers are of a greenish or dingy white, and may be considered as the least ornamental portion of the plant. Seeds of it have germinated freely with Messrs. E. G. Henderson, sown indoors in spring in light rich soil.

RARE ALPINE PLANTS.

IN a list of new plants just issued by Messrs. Backhouse, of York, we find the following, viz.:—*Campanula Zoysii*: A dwarf species from the Tyrol and Carinthia, of great rarity, forming dense tufts bearing narrow pendent lilac-purple flowers. Blooms very freely, and, though delicate in structure, is of free growth in calcareous loam.—*Gentiana affinis*: A distinct and very handsome Gentian, introduced for the first time, forming dense tufts, 6 to 12 inches high, of dark brilliant blue flowers, which not only clothe the upper portion of the stems at each axil, but also form a dense terminal cluster. Allied to *G. gelida* and *G. septemfida*, the foliage reminding of both these species.—*Leucocrinum montanum*: A charming novelty, which may prove a rival to the Snowdrop as an early spring flower. Blossoms pure white, nearly 1½ inches across, borne on a profusion of stalks about 3 inches high, rising from each tuber. Leaves linear, very narrow. Blooms in the wild state with the melting snow.—*Pentstemon humilis*: Densely clustered, 6 to 9 inches high, more than one-half of the entire plant being a series of whorls of brilliant azure, almost "gentian" blue. Very free and pretty for both rock-work and borders. Rocky Mountains.—*P. secundiflorus*: Another new species from the same source, nearly allied to *P. acuminatus*. Judging by

the dried specimens received, it is equally valuable. The plant is rather taller, less glaucous, and has narrower and longer (linear-lanceolate) leaves, and more numerous rather shorter flowers of a deep rose, with blue segments. As the name implies, the blossoms of this species all "look" to one side of the spike. Being from a great elevation, and doubtless perfectly hardy, these and the other new Rocky Mountain Pentstemons will probably prove a great acquisition, the great defect in the varieties of *P. gentianoides* (so well known in gardens) having been their inability to bear severe frost.—*Romanzoffia sitchensis*: A high Alpine from the Rocky Moun-

tains, with dense tufts of crenated leaves not unlike those of a *Sibthorpia* or dwarf *Chrysosplenium*. The numerous flowers, blooming early in spring, are pure white, and are borne on slender branching stalks 4 to 8 inches high. They seem to combine the forms of *Linnaea borealis* and *Saxifraga granulata*. Distinct and pretty.—*Sparaxis pulcherrima* v. *atropurpurea*: A very dark purple-crimson variety of the well-known species, sent by one of our correspondents in South Africa. The gracefulness of this plant, especially for the margins of shrubberies or ornamental water, can scarcely be surpassed.—*S. pulcherrima* v. *floribunda*: Another distinct and highly-beautiful variety, found inhabiting a special district in Caffraria. Flowers very numerous, often quite weighing down the slender wire-like branched spikes, which are sometimes nearly 3 feet in length. The individual blossoms are of a deep shaded pink and white, more or less flaked.—*Veronica saxatilis Grievei*: A variety of the well-known species, differing in having flowers of a deep rose colour. The individual blossoms are much larger than those of *V. fruticulosa*, and are far brighter and finer than those of the plant long known as *V. saxatilis rosea*, being fully equal in size to the finest forms of the blue *V. saxatilis*, and of the same habit and free growth.

Scarlet-fruited Cucurbit (*Abobra viridiflora*).

GLAND-BEARING BELL-FLOWERS.

THE genus *Adenophora*, like the *Platycodon*, is an offshoot from the *Campanula*, appropriately recognised by Fischer as something more than a mere section of that large generic group. Its most important distinctive fea-

ture, and that from which its name is derived, consists in the fact that it possesses a cup-like glandular disc, whose variation in development is of considerable value in determining the specific distinctions of an otherwise very closely allied group of species. The home of the *Adenophoras*, geographically speaking, is in Siberia and Dahuria, where they enjoy a wide range of wild country, a district which, judging from herbarium and description, will yet yield many more interesting and lovely plants for our wild garden decoration than it has even hitherto done, and its con-
